CYCLOPÆDIA:

OR, AN

UNIVERSAL DICTIONARY

OF

ARTS AND SCIENCES.

CONTAINING

An EXPLANATION of the TERMS, and an ACCOUNT OF THE SEVERAL SUBJECTS,

IN THE

LIBERAL AND MECHANICAL ARTS,

AND THE

SCIENCES, HUMAN and DIVINE.

Intended as a COURSE of ANCIENT and MODERN LEARNING.

By E. CHAMBERS, F.R.S.

Floriferis ut apes in saltibus omnia libant,
Omnia nos— LUCRET.

WITH THE

SUPPLEMENT

AND

MODERN IMPROVEMENTS,

Incorporated in one ALPHABET.

By ABRAHAM REES, D.D. F.R.S.

IN FOUR VOLUMES.

VOLUME THE THIRD.

LONDON,

Printed for J. F. and C. Rivington, A. Hamilton, T. Payne and Son, W. Owen, B. White and Son, T. Longman, B. Law, C. Rivington, C. Dilly, H. Baldwin, H. S. Woodfall, J. Robson, J. Knox, W. Domville, G. G. J. and J. Robinson, T. Cadell, A. Hamilton, jun. R. Baldwin, W. Otridge, N. Conant, J. Murray, A. Strahan, W. Fox, S. Hayes, E. Johnson, W. Bent, D. Ogilvy, G. and T. Wilkie, and W. Collins.

CYCLOPÆDIA:

OR, AN

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

K.

K, A double conſonant, and the tenth letter of the alphabet.

This conſonant has the ſound of hard *c*, and is uſed before *e* and *i*, where, according to the Engliſh analogy, *c* would be ſoft; as in the words *kept*, *KING*; at the end of words it is not much uſed, except after *c*, and chiefly in monoſyllables, as *clock*, *back*, &c. It is now properly omitted in many other words, as *muſic*, *public*, &c. It is alſo uſed between a vowel and the ſilent *e* final, as *close*, *broke*, &c. It likewiſe ends a word after a diphthong, as *look*, *brook*, &c. In the preſent pronunciation, *k* is ſilent before *n*.

K is borrowed from the Greek *koppa*; and was but little uſed among the Latins: Priſcian looked on it as a ſuperfluous letter, and ſays, it was never to be uſed except in words borrowed from the Greek. Dauſquius, after Salluſt, obſerves, that it was unknown to the ancient Romans.—Indeed we ſeldom find it in any Latin authors, excepting in the word *kalendæ*, where it ſometimes ſtands in lieu of a *c*.—Carthage, however, is frequently ſpelt on medals with a *K*: SALVS AVG. ET CAES. FEL. KART. and ſometimes the letter *K* alone ſtood for *Carthage*.—M. Berger has obſerved, that a capital *K*, on the reverſe of the medals of the emperors of Conſtantinople, ſignified KONSTANTINUS; and on the Greek medals he will have it to ſignify KOIAH ΣΤΡΙΑ, Cœleſyria.

Quintilian tells us, that in his time ſome people had a miſtaken notion, that wherever the letter *c* and *a* occurred at the beginning of a word, *k* ought to be uſed inſtead of the *c*. See C.

Lipſius obſerves, that *K* was a ſtigma, anciently marked on the foreheads of criminals with a red-hot iron.

The letter *K* has various ſignifications in old charters and diplomas; for inſtance, KR. ſtood for *chorus*, K.R.C for *cara civitas*, KRM. for *carmen*, KR. AM. N. *carus amicus noſter*, KS. *cuos*, KT. *capite tonſus*, &c.

The French never uſe the letter *k*, excepting in a few terms of art, and proper names borrowed from other countries. Abbancourt, in his dialogue of the letters, brings in *k* complaining, that he has been often in a fair way to be baniſhed out of the French alphabet, and confined to the countries of the North.

K is alſo a numeral letter, ſignifying 250, according to the verſe;

K *quoque ducentos & quinquaginta tenebit.*

When it had a ſtroke at top, K, it ſtood for 250000.

K on the French coinage denotes money coined at Bourdeaux.

KAABA. See CAABA.

KAALING, in *Natural Hiſtory*, the name of a ſpecies of ſtarling, common in China, and not unfrequent in the Philippine iſlands. It is black, but its eyes, legs, and beak are yellow. It is eaſily kept tame, and may be taught both to ſing and talk. It eats rice and inſects in its wild ſtate; but when kept in a cage will feed very heartily on bread, and all kinds of fruit.

KAB, in *Jewiſh Antiquity*. See CAB.

KABANI, in the *oriental offices*, a perſon who ſupplies the place of what we call the notary public. All obligations that are valid are drawn by him; and he is likewiſe the public weigh-maſter, and every thing of conſequence ought to be weighed before him.

KABBADE or CABADE, the name of a military habit of the modern Greeks, which they wear under another garment.

KABBALA. See CABBALA.

KABIN, KHABIN, KEBIN, or KUBIN, a temporary kind of marriage, in uſe among the Mahometans.

The *kabin* is contracted before the cadi, in whoſe preſence the man eſpouſes the woman for a certain time, upon condition that if he quits her at the end of that term, ſhe ſhall be allowed a certain ſum of money.

Some authors ſay, that the *kabin* is only permitted among the Perſians, and in the ſect of Ali; but others maintain, that it is practiſed among the Turks.

KABBOS, in *Ichthyology*, the name of an Eaſt Indian fiſh of the muſtela kind. It grows to about two feet long, has no ſcales, but feels ſmooth and ſoft like the eel, and is of a brown colour; the noſe or ſnout much paler than the reſt, and ſpotted with black. The head is obtuſe, and the eyes placed very near the extremity of it.

KABESQUI or CABESQUI, is the name of a piece of money, equal in value to five deniers and a *maille* of French, coined and current only in Perſia. See *Perſian* COINS.

KADARI, or KADARITES. See CADARI.

KÆADAS, καιάδας, among the Lacedæmonians, a dungeon for throwing their criminals into. It was of the ſame nature with the Athenian barathron, or orygma.

KÆRURIAGHAKA, in *Botany*, a name uſed by ſome authors for the tree which affords the gum elemi of the ſhops.

KÆMPFERIA, in *Botany*. See GALANGAL.

KAFER *alibeuk*, in the *Materia Medica*, the name given by Avicenna to the drug we call *bitumen Judaicum*, or Jews pitch.

KAGHU, in *Botany*, a name by which ſome authors have called the cajou, or caſhew-tree, the fruit of which affords us the caſhew-nuts. See ACAJOU and ANACARDIUM.

KAHIASSCE, in the Turkiſh court; an officer of ſtate, anſwering to our maſter of the ceremonies.

KAIEBACA *debari*, in *Botany*, the name uſed by ſome authors for the ARNOTTO or ROCOU, called orleana or orellana by other authors.

VOL. III. N° 192.

KAIMACHAN, among the Turks. See CAIMACAN.

KAKILE, a ſpecies of Eruca. See ROCKET.

The original ſenſe of this word was not the plant now named by it, but the *ſoldanella* or ſea bindweed. This was one of the plants uſed in the making the pot-aſhes, or alkali ſalt for glaſs and ſoap-making, when thoſe manufactures were firſt brought into uſe; and it had both the names from that ſalt. The *kakile* from *kali*, and the *ſoldanella* from *ſoder* or *ſolda*, another name of that ſalt. Dioſcorides calls this *crambe thalaſſia*, and we find the ſame name turned into Latin and ſtill preſerved, and the plant called *braſſica maritima*, and in Engliſh the ſea-cabbage.

KAKOUSA, in *Botany*, a name by which ſome authors have called the tree which affords the gum elemi uſed in medicine.

KALD, a word uſed by Rulandus to expreſs vinegar.

KALE, in *Botany*. See CALE.

KALE. *Sea*. See CRAMBE.

KALED, a word uſed by ſome of the chemical writers to expreſs volatile.

KALENDAR. See CALENDAR.

KALENDS. See CALENDS.

KALI, or GLASS-WORT, *ſolſola*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: the empalement of the flower is permanent, compoſed of five oval obtuſe leaves; the flower has no petals, but has five ſhort ſtamina, which are inſerted in the diviſions of the empalement; it has a globular germen, with a ſhort two-pointed ſtyle, crowned by recurved ſtigmas; the germen becomes a globular capſule, with one cell wrapped up in the empalement, including one large ſeed. There are ſeveral ſpecies.

The name *kali*, or *alkali*, was given it by the Arabians: among naturaliſts it has been alſo called *ſalicornia*, *ſoda*, &c. and in Engliſh, *glaſs wort*, and *ſalt-wort*: though the *ſalicornia* or SALT-*wort* is now made a diſtinct genus.

Kali grows in great abundance in Egypt and Syria; as alſo in Languedoc and Provence, where it is cultivated by the farmers, who ſow whole fields of it to good effect, and in many other places.

Being burnt, its aſhes made into a ley, and boiled with oil, make the beſt ſoap.

Out of the ſame aſhes, called alſo *pulverine*, is extracted a ſalt, called *alkali ſalt*; which mixed with a fine ſort of ſand, makes the fine glaſs called *cryſtal*.

All the ſorts of glaſs wort are ſometimes promiſcuouſly uſed for the making *ſal alkali*; but the greater glaſs-wort with a cochleated ſeed is moſt eſteemed for this purpoſe.

The manner of making it is as follows: having dug a trench near the ſea, they lay laths acroſs it, on which they lay the herbs in heaps; and having made a fire below, the liquor which runs out of the herbs drops to the bottom, and at length thickening becomes *ſal alkali*; which is partly of a black, and partly of an aſh colour, very ſharp and corroſive, and of a ſaltiſh taſte; this when thoroughly hardened, becomes like a ſtone, and is then called ſoude or ſoda. Miller.

An impure ſoda is prepared from it at Montpelier, where the plant is ſaid to be cultivated for this uſe in the ſalt-marſhes; and a purer kind at Alicant in Spain, from a ſomewhat different ſpecies of *kali*. See KELP.

They make ſuch quantities of it in Languedoc, that they export it into ſeveral other countries, but principally into Italy, where the Venetians manufacture it into thoſe beautiful glaſſes which they afterwards return into moſt countries in Europe. However, the ſoda made here is inferior to that brought from Alicant; the beſt is in little dry ſonorous lumps, of a bluiſh grey colour, and full of little eyes, or holes.

The juice of this plant is cathartic and diuretic, accounted good to purge phlegmatic watery humours; and ſerviceable againſt the dropſy, jaundice, and obſtructions of the liver and ſpleen; half a dram of the juice is reckoned a ſufficient doſe; but it is ſeldom or never uſed in England.

This plant abounds greatly with ſea-ſalt, its juices being properly a ſaline, not an inſipid aqueous fluid; but the difference between the produce of this plant when green and when dry, is wonderful in chemical experiments. If diſtilled while freſh and green, it yields an inſipid water; if a pound of it be gathered freſh and hung up to dry, it will yield only three ounces of the dried plant; this being burnt, is more difficult than any other ſubſtance of a ſeeming like texture to be reduced to aſhes; and the aſhes finally produced from this quantity burnt in a potter's kiln, will yield only a dram and a half of a whitiſh ſalt, and this will but ſlightly ferment with aqua fortis. Four ounces of the freſh herb being boiled in water, and that water carefully evaporated, there will be formed near three quarters of an ounce of pure ſea-ſalt, in its own natural cubic form, faſtened to the bottom and ſides of the veſſel; and when no more ſalt will ſhoot, the remaining liquor being carefully diſtilled, increaſing the fire to a proper degree, the water will firſt paſs over, and then a dry volatile ſalt will be raiſed and ſtick to the top and ſides of the veſſel. The ſalts being purified, there will be found, as the reſult of the experiment, that this herb, while growing, contains about one fifth part of its weight of common ſalt. The herb which had been thus boiled being dried, and afterwards again boiled in four or five pints of water, and that decoction evaporated to half the quantity, the liquor will yield ſeveral different ſmells, as that of a honey comb, that of cabbage, and other pot herbs. And after all this, the boiled herb being left to putrefy, yields the ſmell of animal excrements, and in the ſame manner becomes the reſort of flies, and yields a proper place of habitation, and food for numbers of worms hatched out of the eggs of thoſe winged inſects. Henkel, de Affinit. Veget. et Miner.

All the experiments that can be made with the cubic cryſtals of ſalt, formed in the evaporited decoction of this herb, prove them to be common ſalt; and the volatile ſalt raiſed afterwards by fire from that liquor, in which no more of this cubic ſalt would cryſtallize, is found to be high alkali by its fermenting with the acid ſpirits. The juice of this plant, when it has been fit by, in order to ſhoot, and all its ſea-ſalt has been ſeparated from it by that means, being dried away by evaporation, and the remainder calcined; there is found a ſalt and earthy ſubſtance, which has ſomewhat of a lixivial taſte, but does not run to a liquor by being expoſed to the air. This calcined ſubſtance, being mixed with any of the acid ſpirit, but particularly with that of the vitriol, becomes of a beautiful blue colour, not inferior to the fineſt ultramarine.

If the recent herb *kali* be fit to ferment with common water, it yields, in the different ſtages of fermentation, ſeveral very different ſmells; firſt that of pickled cabbage, afterwards that of earth-worms killed in ſpirit of wine, and afterwards that of fiſh and dried herrings. If this matter be after all this diſtilled, it yields a ſpirit very much reſembling the fineſt ſpirit of tartar, and afterwards an empyreumatic oil, exactly reſembling thoſe of animal ſubſtances; but what is remarkable of, that there can be no volatile ſalt extracted from this putrefied maſs by any art. The reſiduum yields a pot-aſh, which effervesces violently with acids, and with the vitriolic acid becomes a ſal enixum; with aqua fortis a maker nitre; with ſpirit of ſalt, it affords common ſalt, ſuch as that ſpirit was diſtilled from: and with all the acids of whatever kind under proper management, it yields the blue colour before mentioned, approaching more or leſs to the fine colour of the ultramarine, according to the nature of the acid and the proceſs. The ſalt extracted from purified pot-aſh, made in this manner, is of a greeniſh caſt like native borax, and the remainder, after the extracting of this ſalt, on mixing and digeſting with aqua fortis, will become a ſoft gelatinous matter of a truly metallic taſte. The *kali* promiſes to be an uſeful article of the materia medica, and has for ſome time paſt been adopted into practice in this country, as it has long been among the French, both by itſelf and combined with tartar into the neutral ſalt called *ſal* RUPELLINE.

KALI, *ſal*. See SALT-WORT.

KALIPH. See CALIPH.

KALMIA, in *Botany*, a genus of the *decandria monogynia* claſs. Its characters are theſe: the flower has a ſmall permanent empalement, and one petal cut into five ſegments, which ſpreadopen; it has ten ſtamina, which are the length of the petal, and decline in the middle; in the centre is ſituated a roundiſh germen, which becomes an oval or globular capſule with five cells, filled with very ſmall ſeeds. There are two ſpecies.

KALKABRE, a name given by ſome of the barbarous writers to *gagates*, or *jet*.

KAMAN, in *Natural Hiſtory*, a name given by many authors to a ſtone found about the burning mountains, and at ſome times uſed to engrave ſeals on. It is deſcribed as a white ſtone, variegated with ſeveral colours.

KAMAR, a word uſed by ſome writers in chemiſtry, to expreſs ſilver.

KAMINE, a name given by ſome to the BUTTER-*ſtone*.

KAN, or KHAN, the name of an officer in Perſia, anſwering to that of *governor* in Europe.

There are *kans* of provinces, countries, and cities, who have different additions to diſtinguiſh them.

KANASTER, is a name given in America to baſkets of ruſhes or cane, in which they put the tobacco which they ſend into Europe: hence ariſes the name of *kanaſter* tobacco, the beſt of which comes from Makaribou.

KANTREFF, or KANTREV. See CANTRED.

KANG, or *Chineſe ſtove*, is a kind of ſtove that is heated by means of a furnace, which calls all its heat into it. The furnace is adapted to the fire of the ſtove which it is intended

KAMAHAHA, in *Botany*. See RHIZOPHORA.

KAOLIN, the name of one of the two substances which are the ingredients of China-ware. The other, which is called PETUNTSE, is easily vitrifiable, and this *kaolin* is scarce at all so: whence the fire composes from a mixture of them both a semivitrification, which is China-ware. See PORCELAIN.

Mr. Reaumur had an opportunity of examining this substance, not in its native state, but only in form of small bricks, made out of the paste of the powder of the native *kaolin* and water. He found it of a white colour, and sprinkled all over with fine glittering particles; but these he did not judge to be fragments of a different substance mixt among the mass, as are the small flakes of talc in our clays and sands; but that the whole mass was composed of some stone reduced to powder and made into a paste with water, and that these larger spangles were only coarser particles of the powder; the examination of which he promised himself would discover what the stone was of which they were formed. And this was the most worthy a diligent enquiry, since the *petuntse* might easily be supplied by many of our own earths and sands; nothing being required of that but a substance easily turning into a white glass. But the difficulty of vitrifying this other ingredient, renders it a thing much more difficult to be supplied by one of the same nature among ourselves. The comparison of these, with other mineral substances, soon proved that they were of the nature of talc; or, in other words, that *kaolin* was talc powdered, and made up into a paste with water. And to be assured whether the whole mass was talc powdered, or any thing else with a mixture of talc, he separated the particles of the *kaolin* by water, and found the small ones wholly the same with the larger; and that the larger, when reduced to powder alone, made with water a paste wholly the same with the *kaolin*. It is well known, that the fragments of talc have a great resemblance to the pearly part of some shell fishes; and hence unquestionably has arisen the opinion of porcelain being made of sea shells: ignorant persons having seen the talc of *kaolin*, and taken it for a shelly matter. Talc has not yet been successfully used in any of our European manufactures of porcelain; but it is easy to see, from many unanswerable reasons, that since China porcelain is made of a mixture of vitrifiable and unvitrifiable matter, nothing is so likely to succeed with us in the place of the last of these as talc.

1. We know no substance in the fossile world so difficult to reduce to glass as talc, which if put into the strongest of ourfires, in a crucible, is not to be vitrified, nor even calcined. 2. We know no substance which keeps so much brightness after having passed the fire as talc, or that is of so pure a white; whence we may also learn that it is not to the *petuntse* alone, that the China-ware owes its whiteness, but that the *kaolin* is instrumental to the giving it that colour. 3. Talc is transparent, nay, and in some degree keeps its transparence after the action of the most violent fire. If we are to make porcelain of a vitrifiable, and an unvitrifiable matter mixed together, yet it is necessary that the unvitrifiable one should retain its transparence, otherwise it would obscure the mass; and talc is therefore the only known substance qualified for this purpose. Persons who have been at the China works, say, that the porcelain is made of equal quantities of *petuntse* and *kaolin*, and it is therefore a just and exact semivitrification. 4. Talc is well known to have a great flexibility or toughness, and as it is found to preserve this even after it has passed the fire; it is very probable, that it is owing to this property of the *kaolin*, that the China-ware is so much less brittle than glass. Mem. Acad. Par. 1727.

It has been before observed, that we may easily in Europe be provided with different substances, which will, in our porcelain manufactures, supply the place of the *petuntse* of China, and talc appears equally qualified to serve instead of the *kaolin*. For this purpose we may use the common Muscovy talc, or isinglass, used by our miniature painters, to cover their pictures instead of glass, and, by the curious, to preserve objects for the microscope; or perhaps the Venetian talc of the druggists, would succeed even better; at least the process is so rational, as to be extremely well worth trying.

But this *kaolin* is more probably an argillaceous earth, from its forming with water a mass tenacious enough to be made into the loaves into which it is brought over. M. Bomare says, that by analysing some Chinese *kaolin*, he found it was a compound earth consisting of clay, to which it owed its tenacity; of calcareous earth, which gave it a mealy appearance; of sparkling particles of mica, and of small gravel or particles of quartz crystals. He says, that he has found a similar earth upon a stratum of granite, and conjectured that it may be decomposed granite. This conjecture is the more probable, as *kaolins* are frequently found in the neighbourhood of granites.

KAPI, a term in the eastern countires for *gate*.

Thus the chief gate of the palace of the emperor of Persia is called *alla kapi*, the Gate of God. Hence also, the officer who has the command of the grand seignor's palace-gates, is called *topighi bachi*.

KARABE. See CARABE.

KARADRE, a name given by the writers of the middle ages to a stone, of which they record many imaginary virtues, such as the rendering people amiable, sprightly, and the like. They describe it to have resembled crystal, but with a mixture of a dusky white. It seems to have been a foul kind of pebble crystal.

KARAITES. See CARAITES.

KARAT. See CARAT.

KARATA, by some called *ceraguata maca*, a kind of aloe growing in America; whose leaves, when boiled, are made into a thread, of good use for making cloth, fishing nets, &c. Its roots or leaves thrown into the water, stupefy the fishes to that degree, that they are easily taken with the hand: its stalk, when dried and burnt, serves for tinder; and when briskly rubbed on a harder wood, it takes fire, and consumes itself.

KARATAS, in *Botany*. See PINE APPLE.

KARFE, a kind of CINNAMON.

KARKRONY, a building where the royal manufactures of Persia are carried on.

Here are made their tapestries, cloth of gold, silk, wool, and brocades, velvets, taffeties, coats of mail, fabres, bows, arrows, and other arms. There are also in it painters in miniature, goldsmiths, lapidaries, &c.

KARLE, a Saxon word, used in our laws, sometimes simply for a *man*, and sometimes for a *servant*, or *clown*.

Hence the Saxons call a seaman a *buscarle*, and a domestic servant a *huscarle*.

KARLE *Hemp*, a term used by our country people for the latter green HEMP.

KASI, a term in the East, applied to the fourth pontiff of Persia, who is also the second lieutenant civil, and judges of temporal as well as spiritual affairs.

He has two deputies, who determine matters of less consequence; particularly quarrels arising in coffee-houses, which make a great part of their business.

KASTRIL, in *Zoology*. See KESTRIL.

KATKIN. See CATKIN.

KATOU-*cerva*, in *Botany*, a name by which some authors have called the tree, whose leaves are the TAMALAPATRA, or Indian leaf of the shops. See MALABATHRUM.

KATOVINDEL, in *Botany*, the name given by the authors of the Hortus Malabaricus, to a genus of plants, called by some *elate*, and by Linnæus phœnix.

KAURYSAOUL, a body of soldiers who form the laſt of the five corps of the King of Perſia's guards.

They are in number two thouſand, and are all horſe, commanded by the conſtable, and in his abſence by the captain of the watch. They keep watch in the night around the palace, ſerve to keep off the croud when the ſophi goes on horſeback, keep ſilence at the audience of ambaſſadors, ſeize the khans and other officers when diſgraced, and cut off their heads when the ſophi commands it.

KAY, KEY, or QUAY, a wharf or place by the water ſide, in a ſea-port, for the loading and unloading of merchandize.

The verb *cajare*, in old writers, according to Scaliger, ſignifies *to keep in* or *reſtrain*; and hence came our term *key*; the ground where keys are made being bound in with planks and poſts.

The lawful *keys* and wharfs for the lading or landing of goods, belonging to the port of London are the following: viz. Cheſter's *Key*, Brewer's *Key*, Galley *Key*, Wool Dock, Cuſtom-houſe *Key*. Bear *Key*, Porter's *Key*, Sab's *Key*, Wiggan's *Key*, Young's *Key*, Ralph's *Key*, Dice *Key*, Smart's *Key*, Somer's *Key*, Hammond's *Key*, Lyon's *Key*, Botolph Wharf, Grannt's *Key*, Cock's *Key*, and Freſh Wharf; beſide Billingſgate, for landing fiſh and fruit; and Bridgehouſe in Southwark, for corn and other proviſions; but for no other goods or merchandiſe. Deal-boards, maſts, and timber, may be landed at any place between Limehouſe and Weſtminſter; the owner firſt paying or compounding for the cuſtoms, and declaring at what place he will land them.

KAYAGE, the money, or toll, paid for loading or unloading wares at kays.

KEAJA, or KIAHIA, is the name of the lieutenant of the chief officers of the Porte, or the ſuperintendant of their particular court.

KEALE, ſmall fragments reſembling chips or broken pieces of ſtone of various kinds; ſome of lime-ſtone, others of free-ſtone, and others of rag-ſtone, found mixed among the earth, of the upper ſtratum in many parts of this kingdom, and giving that ſoil the name of *kealy*; hence, ſome of theſe pieces of *keale* are thin and flat like bits of ſlate.

KEALY *ſoil*, in *Agriculture*, is uſed by the huſbandmen for a ſort of land, plentifully ſtrewed with *keale* or *kale*.

KEBER, the name of a ſect among the Perſians, who, in general, are rich merchants. See GABRES.

KEBLA, or KEBLAH, called alſo KEBLEH, KIBLEH, and ALKEBLA, among the MUSSULMEN, denotes that point, or quarter, to which they turn themſelves when they ſay their prayers.

Mahomet, at firſt, durſt not propoſe any other *kebla* to his followers but the temple of Jeruſalem, which was the *kebla* of the Jews and Chriſtians. In the courſe of time, however, being willing to bring them off from any communication in matters of religion, with the Jews and Chriſtians, he appointed them, in the Koran, to turn themſelves, at prayer, towards the temple of Mecca: from which time they called thoſe two temples the *keblatan*, or two *keblas*.

Ricaut adds, that it is not the temple of Mecca, properly ſpeaking, that the Turks call *kebla*, but rather the large ſquare tower in the middle of the amphitheatre of that temple.

The *kebla* of the Jews was the temple at Jeruſalem; that of the Sabians, the meridian; and that of the Magians, the riſing ſun. To this the prophet Ezekiel refers chap. viii. 16.

KEBLA is alſo uſed for an altar; or rather a *niche*, as Ricaut calls it, which the Mahometans have in all their moſques, and which is placed very exactly on that ſide towards the temple of Mecca.

Hence alſo *kebla* comes to be uſed, metaphorically, for the object, or end propoſed, in doing any thing.

Thus, the *kebla* of kings, is their crown and authority; that of men of buſineſs, is money; that of gluttons, good chear, &c.

KEBLA-NOMA, or KEBLEH-NOMA, a name which the Turks and Perſians give to a little pocket-compaſs, which they always carry with them, in order to place themſelves the more exactly when they go to prayers.

KECKLE, on *board a ſhip*. When the cables gall in the hawſe, or the bolt-ropes do ſo againſt the ſhip's quarter, the ſeamen wind ſome ſmall ropes about them; and this is called *keckling*.

KEDGER, or KEDGE-*anchor*, in a ſhip. See ANCHOR.

KEDGING, a ſea-term uſed when a veſſel is brought up or down a narrow river by the wind, though the tide be contrary to it.

To do this, the ſeamen [illegible] and mizen-ſails, and let [illegible] they may ſail [illegible] ſhore, they have a [illegible] or *kedging-anchor*, [illegible] ſhip; and this they [illegible] which means they [illegible] take up the anchor again.

KEDRELÆON, [illegible] *Apocynum*, an [illegible] cedar-tree.

KEEL, the loweſt piece of [illegible] bottom of her hull, [illegible] ſtern-poſt, and the [illegible] If we compare the [illegible] human body, the *keel* [illegible] and the timbers [illegible] unites the whole [illegible] are elevated [illegible] tion of the *keel* [illegible] nuities of the ſides [illegible] unites the bottom [illegible] compoſed of ſeveral [illegible] which, after being [illegible] ed upon the upper [illegible] procured long [illegible] *keel*, there is a ſtrong [illegible] bottom thereof, called [illegible] When a ſhip [illegible] *keel*; and this [illegible] *Ship*, fig. [illegible]

KEEL is alſo a name [illegible] uſed in the river [illegible] Newcaſtle, and [illegible] colliers for tranſporting [illegible]

KEEL, *upon an even*, in *Sea Language*, [illegible] of a ſhip when [illegible] parallel [illegible] zon, ſo that the [illegible]

KEEL-*hauling*, or [illegible] puniſhment inflicted [illegible] great offenders, [illegible] of the ſhip. See DRAWING.

KEELAGE, *Hithernage*, [illegible] the bottom of ſhips [illegible]

KEELERS, in the *Sea Language*, ſmall tubs to hold ſtuff to grave a ſhip's bottom.

KEELING, a name uſed in ſome Engliſh writers for the common COD-FISH. See ASELLUS.

KEELSON, in a *ſhip*, the next piece of timber to the *keel*, lying right over it next above the floor-timber.

KEEP, *to*, in *Sea Language*, is a term uſed on various occaſions: as

To KEEP *the land aboard*, is, to *keep* within ſight of land as much as poſſible. See HOLD.

To KEEP *the luff*, is to continue cloſe to the wind, or to ſail with a courſe inclined to the direction of the wind as much as poſſible, without deviating to leeward. This is alſo called *keeping the wind*. See CLOSE-*hauled* and LOOF.

To KEEP *off*, is to ſail off, or *keep* at a diſtance from the ſhore. See OFFING.

KEEPER *of the foreſt*, otherwiſe called *chief warden of the foreſt*, is an officer who has the principal government of all things belonging to a royal foreſt, and the chief of all the other officers.

The lord chief juſtice in eyre of the foreſt, when he thinks fit to hold his juſtice ſeat, ſends out his general ſummons to the *keeper* forty days before, to warn all under-officers to appear before him, at a day alligned in the ſummons. See JUSTICE *of the foreſt*.

KEEPER *of the great-ſeal*, is a lord by his office, and is ſtyled *lord keeper of the great-ſeal*. He is one of the king's privy-council, through whoſe hands paſs all charters, commiſſions, and grants of the king under the great ſeal; without which ſeal, all ſuch inſtruments, by law, are of no force: for the king is, in the interpretation of the law, a corporation, and paſſes nothing firmly but under the ſaid ſeal; which is, as the public faith of the kingdom, in the higheſt eſteem and reputation.

The lord *keeper* has the ſame place, authority, pre-eminence, juriſdiction, execution of laws, and all other cuſtoms, commodities, and advantages, as the lord chancellor of England has for the time being. Both theſe officers cannot properly ſubſiſt at the ſame time, ſince the ſtatute of 5 ELIZ. The lord CHANCELLOR, or lord *keeper*, is ſuperior in point of precedency to every temporal lord.

KEEPER *of the privy ſeal*, is a lord by his office; through whoſe hands paſs all charters ſigned by the king, before they

they come to the great-seal, and some things which do not pass the great-seal at all. He is of the king's privy-council, and was anciently called *clerk of the privy-seal*: Yet reckoned in the number of the great officers of the realm. 12 Ric. II. c. 11. 27 Hen. VIII. c. 11.

KEEPER, *boat*, in *Sea Language*, one of the rowers, who remains as a centinel in his turn, to take care of any boat and her contents, either when she lies by the shore, or along-side of the ship; or when she is towed a-stern of her.

KEEPING, in *Painting*, denotes the representation of objects in the same manner that they appear to the eye, at different distances from it, for which the painter should have recourse to the rules of perspective. There are two instances in which the famous Raphael Urbin has transgressed these rules: in one of his cartons, representing the miraculous draught of fishes, the men in each of the two boats appear of full size, the features of their faces being strongly marked; and the boats are represented so small, and the men so big, that any one of them appear sufficient to sink either of the boats by his own bare weight: and the fowls on the shore are also drawn so big, as to seem very near the eye of the observer; who could not possibly, in that case, distinguish the features of the men in the distant boats. Or, supposing the observer to be in either of the boats, he could not see the eyes or beaks of the fowls on the shore. The other instance occurs, in his historical picture of our Saviour's transfiguration on the Mount; where he is represented with those who were then with him, almost as large as the rest of his disciples at the foot of the Mount, with the father and mother of the boy whom they brought to be cured; and the mother, though on her knees, is more than half as tall as the mount is high. So that the mount appears only the size of a little hay-rick, with a few people on its top, and a greater number at its bottom on the ground; in which case, a spectator at a little distance, could as well distinguish the features of those at the top as of those on the ground. But upon any large eminence, deserving the name of a mount, that would be quite impossible.

KEEPITHEJA, in *Botany*, the name by which some authors call the tree, on the branches of which the gum lacca of the shops is usually found.

KEEVE, or KEEVEL, a large tub, or brewing vessel, in which ale or beer ferments, before it is tunned.

KEIKEM, in the *Materia Medica*, a name given by the Arabian writers, to a gum used in their time for making of varnish.

Gum lacca is generally said to be the substance meant by it, but Avicenna seems to express by it every thing that was used as varnish. Thus he sometimes means by it the gum sandarach, and sometimes amber. The *gum-cancamum* of the Greeks is also certainly often meant by it; but this is scarce to be mentioned as an explication of the word, it being almost as general a term as itself, and standing with many of the old authors for sandarach, gum lac, and amber, as well as for the gum properly expressed by it. In short, all the gums used in making varnish, are in general called by the names of any one of them, and thus vernix, sandarach, cascamum, and lacca, are made synonymous words, and either stands for each of the things signified by all the words.

KEIRAN, in the *Oriental Learning*, the Persian and Arabic name for the planet Saturn, according to Salmasius. See CHIUN.

KEKIO. See PERN-*oil*.

KELMEJAN, in *Botany*, a name given by some authors to the acacalis, or wild carob-tree.

KELP, in the *Glass-Trade*, a term used for a sort of pot-ashes used in many of their works, particularly for the crystalline metal. It is the calcined ashes of a plant, called by the same name, and in some places sea-thongs, or laces, a sort of thick-leaved fucus or sea-wrack: the *alga angustifolia vitriariorum* of John Bauhine. This plant, if kept moist a little after gathering, will shew afterwards, though long kept, its white salt upon the surface of its leaves. This plant is thrown on the rocks and shores in great abundance, and in the summer months is raked together, and dried as hay in the sun and wind, and afterwards burnt to the ashes called *kelp*, which are used not only in the glass, but in the alum works. This contains an alkali of the same kind with the plant KALI, but more impure.

KEMA, in *Natural History*, a name given by Leo Africanus, and other writers of the African history, to a sort of subterranean production of the vegetable kind, greatly esteemed as a delicious food. The Arabian writers on medicine have often mentioned it, and that under names sufficiently resembling the modern African appellation, such as *cumbe*, *cumah*, *kemah*, and *camba*. They are not the roots of any plant, but a fine kind of subterraneous mushroom, or truffle, white on the outside, and which is generally pretty deep in the earth.

KENKS, in the *Sea-Phrase*, are doublings in a cable of rope, when it is handed in or out, so that it does not run smooth, or when any rope makes turns, and does not run smooth and clever in the block, they say it makes *kenks*.

KENNEL, a term used indifferently for a puddle, a watercourse in the streets, a house for a pack of hounds, and the pack or cry of hounds themselves.

Among sportsmen, a fox is said to *kennel*, when he lies close in his hole.

KENNETS, in our *Old Writers*, a sort of coarse Welsh cloth, mentioned in the stat. 33 Hen. VIII. c. 3.

KENNETS, in a *Ship*, are small pieces of timber, nailed to the inside of the ship, unto which the tacks and sheets are belayed (as they call it) i. e. fastened.

KEPLER'S *Laws*, is that law of the planetary motions, discovered by Kepler: in reality, Kepler discovered two of the fundamental laws of the mundane system, viz. 1. That the planets describe about the sun are as proportional of the times; and 2. That the squares of the times of revolution are as the cubes of the mean distances of the planets from the sun. Sir I. Newton has shewn, that the first of these laws results from a centripetal force which urges the planets towards the sun, and the second, from the centripetal force being in an inverse ratio of the square of the distance.

KEPLER'S *Problem*. See PROBLEM.

KERAMIANS, a sect, among the Mussulmen, so called from Mohammed Ben Keram, its author.

The *Keramians* maintain, that whatever the Alcoran says of the arms, eyes, and ears of God, is to be understood literally: so that they admit the tagisdum, that is, a kind of corporeity in God; which, however, they explain very variously.

KERANA, a long sort of trumpet; somewhat in form of a speaking-trumpet, used by the Persians.

To the sound of this, they add a confused noise of hautboys, timbrels, drums, and other instruments, every evening at sun-set, and two hours after midnight.

KERATOPHYTUM, a name by which Boerhaave expresses the black coral, called also ANTIPATHES, *lithophyton*, and *pseudocorallium*.

The *keratophyta*, in the Linnæan system, are a species of the GORGONIA: they are called the *frutices coralloides*, or sea-shrubs, and generally known among naturalists, by the different appellations of *lithophyta*, *lithoxyla*, and *keratophyta*; epithets intended to convey an idea of their composition, which, at first view, seems to consist partly of a woody or horny, partly of a stony or calcareous substance, variously disposed with respect to each other. Their general form approaches to that of shrubs, having a root-like base, by which they adhere to some solid support in the ocean; and a stem, or trunk, and branches differently disposed; some rising up in one or more different twigs, subdivided into smaller and separate ramifications; while others have their smaller branches connected in such a manner, as to form a curious net-like structure: from this diversity of figure, they borrow the names of sea-fans, sea-feathers, &c. The seeming fibres of the base are, in reality, small tubes, of which the whole shrub consists: these tubes run up longitudinally into the trunk, and are also circularly disposed about the centre of the trunk; the woody part, as naturalists have called it, thus formed, affords, when burnt, a strong smell like burning horn; whence some have called it the horny part. Upon this part is superinduced, a kind of stony or calcareous coat, which covers both trunk and branches to their extremities. In this coat may be discovered, regular orders or pores of cells; and viewed by the microscope, it always appears to be an organical body, consisting of a regular congeries, like the cells in which animals have been formed or existed. Some of this kind of bodies have lost their calcareous covering by the violence of the waves, and other accidents. In some specimens of an advanced growth, the calcareous tubes, just mentioned, find out little cells of animals of the polype kind, with proper openings to them all: these cells are diffused along the branches in some regular order, much in the same manner as they are in the corallines. From the cells, the animals have been discovered extending themselves as well to procure food as materials for the increase of this surprising structure: and, therefore, there is no reason to doubt, that they are animal productions: a small sprig of the *keratophyton flabelliforme, cortice verrucoso obductum*, or warted sea fan, is represented in *fig.* 7. *Tab.* II. *Corallines*. The outside is covered with a crust, full of little lumps like warts; which, when dissolved in vinegar, discover the contracted bodies of polypes, like claws. C and C 1 are two views of one of the warts magnified: C 2. is the appearance of the polype, when the cretaceous matter was dissolved: C 3. represents the particles that compose the incrustation magnified. D, fig. 8. represents a sea-willow,

willow, or *keratophyton dichotomum, caule & ramulis leviter compressis*. On both edges of the flat branches, are regular rows of little rising cells in the calcareous part, with small holes for an entrance to each. Ellis's Hist. of Corallines, chap. 5. See CORALLINES.

KERF is the notch or slit that is made by the saw between two pieces of wood, when they are sawing asunder.

KERFE-KARUMFEL, in the *Materia Medica*, a name given by Avicenna, and others, to the wood of the clove-tree, as the wood of the cinnamon-tree was called *berse darsini*; and many others in the same manner.

KERI *Cetib*, are various readings in the Hebrew Bible: *keri*, signifies that which is read; and *cetib*, that which is written. For where any such various readings occur, the wrong reading is written in the text, and that is called the *cetib*; and the true reading is written in the margin, with ק under it, and called the *keri*. It is generally said by the Jewish writers, that these corrections were introduced by Ezra; but it is most probable that they had their original from the mistakes of the transcribers after the time of Ezra, and the observations and corrections of the Masorites. Those *Keri-chetibs*, which are in the sacred books written by Ezra himself, or which were taken into the canon after his time, could not have been noticed by Ezra himself; and this affords a presumption, that the others are of late date. These words amount to about a thousand; and Dr. Kennicott, in his Dissertatio Generalis, remarks, that all of them, excepting fourteen, have been found in the text of manuscripts.

KERMES, a kind of little animal, found in great plenty on an evergreen of the oak kind, and forming excrescences or *nidules*, of considerable use, both in physic and dying. See COCCUS.

The *kermes*, called also *scarlet grain*, and by the Greeks *coccus baphica*, by the Latins *vermiculus*, by the French sometimes *vermillon*, or *grain de gale*, or *vermeil*, is about the size of a juniper-berry, round, smooth, and glossy; of a beautiful red colour, and full of a mucilaginous juice, of the same dye; it is found adhering to the bark on the stem and branches of a peculiar sort of scarlet oak.

The *kermes* is the most famous, and most valuable creature of its kind, and is properly an insect of the gall-insect class, and of that genus whose figure resembles a sphere, from which a small part had been cut off. This species is found on a particular kind of the ilex, known by the name of the *ilex aculeata coccigiandifera*. This never arises beyond the height of a small shrub, and is very plentiful in the uncultivated parts of Provence and Languedoc, and in some other places; as in Spain, in the islands of the Archipelago, and particularly in Crete. The peasants make their harvest of these animals, from off these shrubs, at the proper season; and though the history of this drug is a subject well worthy the attention of every naturalist, yet it is but of very late years that it has been enquired into with any degree of accuracy. Messrs. de la Hire and Sedileau opened a way to the knowledge of it, by their history of the gall-insect of the orange-tree; but all the advantages that might have been expected thence, were not soon obtained, nor was the resemblance and strict analogy between the flat and spherical gall-insects so soon observed, as might have been expected.

The *kermes*, when at his full growth, appears a small shell fixed to the branches of this shrub, or seems a purse or bag, the covering of which is sufficiently strong, bright, and shining, and of the colour of a ripe plum, and covered with the same sort of whitish powder, as that fruit is when ripe. This powder, the people of the place call the flower of the *kermes*. Those who have never seen *kermes* otherwise than in the shops of the druggists, may naturally think it of a reddish brown; but this is not its natural colour, but it is the effect of the vinegar they use for its preservation; that remaining on the branches, and which has not been affected by vinegar, having nothing of this colour, but exactly that of ripe sloes in the hedges.

There are two kinds of *kermes*; the one, that which has been already described, which is of the colour of a plum, and which lays red eggs. The other is whitish, or somewhat reddish, and is covered in the same manner as the other, with a white powder, and lays its eggs in the same manner. Its growth is the same with the other, and at the same seasons, and its eggs are white.

The young insects produced from both these species, are very like, and have a considerable resemblance to woodlice, or millepedes, as indeed have the young of all the gall-insect class. They differ however in colour: those which are produced from the red eggs, are themselves red; they are flat in shape, and somewhat more pointed behind than at the head; their back is convex, with a round arched prominence. This kind has several shining gold-coloured spangles, and is traited on the back, and has several transverse lines across the belly. It has six legs, and two horns nearly as long as his body, and a tail split into two, or forked, the divided parts being nearly as long as his horns, and its eyes are black and shining.

The young ones produced from the white eggs, are of a dirty white; their back is somewhat flatter than that of the others, and the spangles on them, viewed by the microscope, appear of a silver colour, not of a gold. There are a much smaller number of these white than of the red *kermes*, and the people of the country call them the mother of the *kermes*. There are also among the *kermes*, several found, containing, instead of these eggs, the nymphs of two kinds of small flies, which regularly are produced from them, and have both a power of hopping or jumping. The one species of fly is of a fine jet black, and the other is of a dirty white. One of these is a white-winged fly, alike, in all respects, to the gall-insect fly, and is, without all doubt, the male *kermes*; though this very observation of a fly being produced from some of the *kermes*, has been one great occasion of believing the *kermes* to be a true gall.

According as the winter has been more or less mild, the harvest of *kermes* is the more or less plentiful; and the people always presage themselves a fine season, when the spring has been free from frosts and fogs. It is observed, that the lowest and oldest shrubs, are always the fullest of this insect; and the *kermes* produced on those trees, which are in the neighbourhood of the sea, is always larger and finer than from the inland places.

It is no uncommon thing to have two harvests of *kermes* in a year. Those of the latter season are smaller and less valuable than those of the first, and are found not on the branches, but on the leaves of the shrub; which is just analogous to the custom of the gall-insects of all other kinds; all which, about this age, leave the branches to feed on the leaves, where their yet tender trunks can find an easier entrance. See *Tab. of Insects*, N° 36.

From this analogy between the *kermes*, and other insects of the same class, it should seem worth while to try, whether some of those may not possess the same virtues in medicine, at least, if not in the arts. It is certain that the common oak produces a red gall-insect of the very shape of the *kermes*, and of the colour of the paler ones. Reaumur, Hist. Insect. p. 45.

The *kermes* is of a vinous smell, a bitter, rough, agreeable taste; and its pulp, or juice, is pregnant with numerous minute ova.

The animal retains these ova under her belly, till they hatch into a very numerous offspring.

Hence, when the *kermes* is dried, there comes out of it an infinite number of little insects, and flies, so small, that they are scarce visible; insomuch, that the whole inward substance seems converted into them. To prevent this inconvenience, they usually steep the *kermes* in vinegar before it be dry; and thus prevent the exclusion of the ova, and kill such animals as are already hatched. They draw the juice, or pulp, from the *kermes*, by pounding it in a mortar, and then straining it through a sieve: of this they make a syrop, by adding a sufficient quantity of sugar. Sometimes they dry the pulp separate from the husk; which pulp, thus dried, they call *paste of kermes*.

The *kermes* again is of great use in physic: it is cardiac, deficcative, and astringent; it fortifies the stomach, and prevents abortion. Of this is made that celebrated confection called ALKERMES.

The restringent and corroborant confection sold in the shops, is prepared by dissolving, in the heat of a water-bath, six ounces of fine sugar, in six ounces, by measure, of damask rose-water; then adding three ounces of the juice of *kermes*, warmed and strained; and after the whole has grown cold, mixing half a scruple of oil of cinnamon. This confection is taken, from a scruple to a dram, or more, either by itself, or in juleps, with which it mingles uniformly, without injuring their transparency.

The dried grains of *kermes*, if they have not been too long kept, give out, both to water and to rectified spirit, the same deep red colour, and nearly the same kind of smell and taste with those of the expressed juice. The inspissated extracts are considerably bitter, astringent, and of a kind of mild balsamic pungency.

It is, however, of greater use in dying scarlet; for which use the manner of preparing it is as follows: the *kermes* being taken when ripe, they spread it on linen, and at first, while it abounds most in moisture, turn it twice or thrice a day, to prevent its heating, till such time as there appears a red powder among it: this they separate, by passing it through a sieve, and then again spread abroad the grain on the linen, till they perceive the same redness of powder, when they repeat the sifting: thus they

they proceed, while they diſcover any red powder on the ſurface of the grain, which is ſtill paſſing through the ſearce, till it yield no more.

In the beginning, when the ſmall red grains are found to move, as they will always do, they are ſprinkled over with ſtrong vinegar, and rubbed between the hands.—Were not this precaution taken, out of every grain would be formed little inſects, which would be of no uſe in dying.

The grain being quite emptied of its pulp, or red powder, by the proceſs above mentioned, is waſhed in wine, and then expoſed to the ſun; after this, it is put up into the huſks, formed into balls, and along with it the proportion of red duſt that it had afforded.

According to M. Marſigli's experiments, made at Montpellier, the *kermes* has the effect of galls; when mixed with vitriol; and makes a good ink: mixed with oil of tartar, or lime-water, its colour turns from a vermilion to a crimſon colour. In a decoction of turnſol flowers, it retains its proper colour. They have not been able to get any fixed eſſential ſalt from it; but a volatile ſalt it yields in abundance; which, in M. Marſigli's opinion, would have a better effect in medicine, if taken in a liquid, than when enclosed in conferves and confections, which hinder its action.

Woollen cloth, prepared with alum and tartar, acquires, on being boiled with dry *kermes* berries, a durable deep red colour, called *ſcarlet in grain*, from the *kermes* having been formerly ſuppoſed to be the grain or ſeed of the tree; and *Venice ſcarlet*, from the greateſt quantities having been dyed there. This colour wants the luſtre and fire of the cochineal ſcarlet now in vogue, but in return is far more permanent, nor ſubject to be ſtained by dirt, or acrid liquors; and when ſpotted with greaſe, may be cleaned again without injury to the colour.

Mr. Hellot obſerves, that the figured cloths to be ſeen in the old tapeſtries of Bruſſels, and the other manufactures of Flanders, which have ſcarcely loſt any thing of their liveline ſs in ſtanding for two hundred years, were all dyed with this ingredient: that nevertheleſs *kermes* is at preſent entirely in diſuſe among the European dyers, though ſaid to be commonly employed in the Levant, and exported thither from Marſeilles in conſiderable quantities: that when the *kermes* ſcarlet (now called an ox-blood colour) is wanted for tapeſtries, &c. our dyers endeavour to imitate it with cochineal; that as the colour is difficultly hit with cochineal alone, they generally add a portion of Brazil wood; and that the dyes thus produced, though at firſt more vivid than they ought to be, often loſe their luſtre before a year is at an end, and turn white and grey in an extraordinary manner: that *kermes* might again be introduced to very good advantage, as its colour is of the moſt durable kind, and as ſundry ſhades are obtainable from it with leſs trouble and expence than from other drugs.

The ſame author has given a great number of experiments upon *kermes*, with different ſalts and metallic ſolutions. The principal of theſe are as follow:

On adding to the decoction of *kermes*, a ſmall quantity of ſolution of tin, the dark colour of the liquor is immediately brightened, and prepared woollen dyed therein, inclines more to the orange than with the *kermes* alone. With this improvement of the colour, it receives the imperfections, though not all the beauty of the cochineal ſcarlet; all alcaleſcent ſubſtances ſtaining the cloth, that is, deſtroying the effect of the acid ſolution.

Kermes, with cream of tartar, and as much of the ſolution of tin as is employed for the cochineal ſcarlet (without any alum) dyed unprepared cloth of an extremely vivid cinnamon colour. On dipping the cloth in a ſolution of alum, a part of the red re-appeared, but was not beautiful.

With cream of tartar, ſolution of tin, and alum in larger quantity than the tartar, this drug gives purpliſh colours, which vary according to the proportions of the ingredients.

If vitriolated tartar be ſubſtituted to the alum and tartar; and if after the *kermes* has been boiled in a ſolution of a ſmall quantity of this ſalt, the ſtuff be boiled in this mixture for about an hour, the dye proves a beautiful kind of grey, in which the red is little perceived.

Glauber's ſalt, employed along with *kermes*, entirely deſtroys its redneſs, and gives an earthy grey colour. This dye is very periſhable, on account of the particular nature of the ſaline ſubſtance, by means of which the tinging particles are applied; for Glauber's ſalt diſſolves eaſily in cold water, and falls into a powder in the ſun's heat. This obtains equally in all dyes; thoſe drugs which afford moſt durable colours with tartar and vitriolated tartar, give very periſhable ones with the more diſſoluble and calcinable ſalts.

Green and blue vitriol, ſubſtituted ſeparately to alum, but taken in conjunction with cream of tartar, deſtroy likewiſe, or conceal the red colour of *kermes*, which in theſe two experiments has the ſame effect with galls, for it precipitates the iron of the green vitriol which tinges the cloth of a bright grey, and the copper of the blue, which gives a kind of olive dye. It likewiſe gave an olive dye with ſolution of copper made in aqua fortis; a certain mark, that it poſſeſſes, like galls, an aſtringent precipitating quality. It is probably the aſtringency of *kermes*, that renders its dye ſo durable; for all the barks, woods, roots, and other ſubſtances that are aſtringent, yield permanent colours.

White vitriol, employed with cryſtals of tartar, changes the red colour of *kermes* into a violet. A tincture of biſmuth ore, in ſpirit of nitre, and a ſolution of biſmuth itſelf made leiſurely in four times its weight of ſpirit of nitre, diluted with an equal quantity of water, gave alſo a violet dye upon white cloth. See Neumann's Chemiſtry, by Lewis, p. 508, &c.

KERMES *mineral*. The *kermes mineral* was a preparation of Glauber, which the king of France bought of M. de la Ligerie, and made public in 1720. That receipt was in the following form: take a pound of Hungarian antimony, broken into thin pieces, according to the direction of its ſpicula; four ounces of nitre, fixed by chaucoal; and a pint of rain water: boil them two hours; then ſiltre the warm liquor, and when it cools, the *kermes* precipitates. The ſame antimony undergoes the ſame operations with the remaining liquor, to which three ounces of fixed nitre, and a pint of water is added. In a third boiling, two ounces of nitre, and a pint of water are to be added to the former lixivium. The *kermes* thus obtained is about a dram, and is well edulcorated by waſhing it with water, and burning ſpirit of wine on it; then it is dried for uſe.

Mr. Geoffroy ſhews, by many experiments, that the *kermes* is the reguline part of the antimony, joined to a ſort of *hepar ſulphuris*. He teaches us a much eaſier way of preparing this medicine, thus: mix intimately the fine powder of two parts of antimony, and one of any fixed alkaline ſalt, melt thoſe metals in a crucible; then having powdered them while hot, boil them two hours in a large quantity of water; after this, paſs the hot liquor through paper, receiving it into a veſſel, in which there is hot water, the *kermes* ſeparates when it cools. The groſſer parts, which do not paſs through the paper, are to be boiled again, and filtrated as before; and the operation is to be repeated a third time, by which ſix or ſeven drams of *kermes* may be got out of every ounce of antimony. He ſays, he has ſeen effects like to thoſe of mild *kermes* from antimony, reduced to ſuch a fine powder, that none of the ſhining ſpicula are to be ſeen; and that the magiſtery of antimony, made by pouring ſpirit of nitre, or aqua regia, on the powder of antimony, and then edulcorating the maſs with water, has the ſame effects as *kermes*. Mem. de l'Acad. des Sciences, 1734, 1735.

Half a grain, or a grain of this powder, given every three or four hours, produces no violent effects; but by increaſing the doſe, it may be made to vomit, purge and ſweat.

When ſeven or eight grains are taken at once, it chiefly acts upon the primæ viæ, generally as an emetic and purgative. A doſe of three or four grains is ſeldom emetic, and more frequently purgative. When taken in theſe quantities as an evacuant, a little of it paſſes alſo into the viæ ſecundæ & tertiæ. When it is adminiſtered in ſmaller doſes, it paſſes almoſt entirely into the lacteal, blood and lymphatic veſſels. In theſe it occaſions ſuch ſpaſms and oſcillations as it does in the primæ viæ; ſo that it increaſes all ſecretions and excretions, but particularly thoſe of urine, ſweat, and expectoration; according to the doſe, the nature of the diſeaſe, and the diſpoſition of the patient. It produces ſingularly good effects in thoſe diſeaſes of the breaſt which proceed from fulneſs and obſtruction. It may be adminiſtered in any vehicle, or incorporated in a bolus, with other ſuitable remedies. But it ſhould never be joined with acids, when it is deſigned to act as *kermes*.

Some commend this medicine as the moſt univerſal reſolvent, and deobſtruent; aſſuring us, that it almoſt infallibly cures pleuriſies, peripneumonies, aſthmas, catarrhs, anginæ, ſmall-pox, and many other diſeaſes. Others are as poſitive, that it heats and thickens the blood, thereby increaſing obſtructions, and is particularly hurtful in all inflammatory diſeaſes.

This preparation was famous in France, and known by the name of *poudre des Chartreux*, becauſe a Carthuſian monk, who got it from Mr. de la Ligerie, firſt brought it into vogue. See Hiſt. de l'Acad. des Sciences 1720, and the Memoirs for the ſame year, where it is ſaid that Glauber was looked upon as the firſt inventor of this remedy.

Its effects, like that of many other antimonial preparations, are very various, which is frequently owing, as Mr. Geoffroy obſerves, to the different manner and care in making it. He adds, that the more the *kermes* contains of a regulus eaſily revivified, the more it proves emetic. He alſo ſhews how to make a cinnabar with the *kermes* and mercury, and to diſengage the vitriolic acid from the *kermes*. See Mem. de l'Acad. des Sciences, 1734.

KERN, or KERNE, a term in the ancient Iriſh militia, ſignifying a *foot-ſoldier*.

Camden tells us, the armies of Ireland conſiſted of cavalry, called *gall glaſſes*; and infantry, lightly armed, called *kerne*. The *kerne* bore ſwords, and darts; to the laſt were fitted cords, by which they could recover them after they had been launched out.

KERN, in the *Engliſh ſalt-works*, a word uſed to ſignify the cryſtallizing, or ſhooting of ſalt in the brine, when ſufficiently evaporated in the boiling pan.

This word is alſo uſed by the ſeamen for the firſt forming of the bay-ſalt, made by the ſun's heat in the iſles of May, &c. See SALT.

KERN-*ſtone*, in *Natural Hiſtory*, a name given by the common people of many parts of England, to a peculiar ſort of ſtone, which is found on the ſides of hills in ſandy countries, where the hills are rocky. Pyran ſands afford a great many ſtones of this kind; and the manner of their formation is thus: the rocks in the ſides of the hills are continually covered over with the looſe ſand, which the winds toſs up, and the ſparry matter continually oozing out of the pores of theſe ſtones, with the wet, cements the grains of ſand together. When one cruſt is thus formed, another is ſoon added, and ſo on, till the whole maſs is of a conſiderable thickneſs; and the ſpar ſtill ſerving as a general cement, the whole is held together, though but in a looſe way, yet ſo as to reſemble a ſort of ſtone. The little grains of ſand are ſtill viſible in all parts of this ſtone, and are what induced the people to call it *kern-ſtone*, as they call theſe *kerns*, or *kernels*. This account of the origin of the ſtone is eaſily proved, by putting a ſmall piece of it into aqua fortis, for this diſſolves the ſpar, or cement, and the ſand is left looſe.

KERNES, in our *Laws*, ſignify idle perſons, or VAGABONDS.

KERNING, in *Letter-Founding*. See *Letter* FOUNDERY.

KERSEY, a kind of coarſe woollen cloth, made chiefly in Kent and Devonſhire.

KESITAH. This word is to be met with in Geneſis, and in Job; and is tranſlated in the Septuagint and Vulgate ſheep or lambs. But the Rabbins and modern interpreters are generally of opinion, that *Keſitah* ſignifies rather a piece of money. Bochart and Eugubinus are of opinion the Septuagint meant *minæ*, and not *lambs*; in Greek *hecatommion*, ἑκατομμοιον, inſtead of ἑκατον αρνων. Now a mina was worth ſixty Hebrew ſhekels, and conſequently ſix pounds ſixteen ſhillings and ten pence half-penny ſterling. M. de Pelletier of Rouen, is of opinion, that *Keſitah* was a Perſian coin, ſtamped on one ſide with an archer (*Keſitah* or *Keſeth*, in Hebrew, ſignifying a *bow*) and on the other with a lamb; that this was a gold coin known in the Eaſt by the name of a Darie, and was in value about twelve livres and ten pence French money. Several learned men, without mentioning the value of the *Keſitah*, ſay it was a ſilver coin, the impreſſion whereof was a ſheep; for which reaſon the Septuagint and Vulgate tranſlate it by this name. Calmet is of opinion, that *Keſitah* was a purſe of gold or ſilver. In the Eaſt they reckon at preſent by purſes. The word *Kiſta* in Chaldee ſignifies a meaſure, or veſſel. And *Euſtathius* ſays, that *Kiſta* is a Perſian meaſure. Jonathan and the Targum of Jeruſalem tranſlate *Keſitah* a Pearl. Gen. xxxiii. 19. Job xlii. 11. Or nine pounds Engliſh, ſuppoſing, as Dr. Prideaux does, that a ſhekel is worth three ſhillings. A Darie is a piece of gold, worth, as Dr. Prideaux ſays, five and twenty ſhillings Engliſh. See his Connect. P. I. p. 101. See Calmet Comment. upon Gen. xxxiii. 19. Gen. xxv. 12. Job xlii. 2. &c. and Dict. Bibl.

KESTREL, the Engliſh name of a hawk, called alſo the *ſtannel* and the *windhover*, and by authors the tinnunculus and *cenchris*. It builds with us in hollow oaks, and feeds on partridges and other birds.

KETCH, a kind of veſſel, equipped with two maſts, viz. the main-maſt, and mizen-maſt, and uſually from one hundred to two hundred and fifty tons burthen: they are uſed either as yachts, for conveying princes of the blood, ambaſſadors, or other great perſonages, from one place to another, or as BOMB-*veſſels*: theſe are built remarkably ſtrong, and fitted with a greater number of RIDERS than any other veſſels.

KETMIA, in *Botany*, ſee *Syrian* MALLOW.

KETRAN, KITRAN, or ALKETRAN, a name given by ſome of the Arabian authors to the oil of cedar, called by the Greeks CEDRIA. We have of later times formed the word *cedrenum* upon this, and it has ſince been applied to the zopiſſa of the ancients, a compoſition made of pitch and wax melted together, and uſed for covering the bottoms of ſhips.

KETTLE, in the *Art of War*, a term the Dutch give to a battery of mortars, becauſe it is ſunk under ground.

KETTLE-*drums* are formed of two large baſons of copper or braſs, rounded at the bottom, and covered over with vellum or goat-ſkin, which is kept faſt by a circle of iron, and ſeveral holes faſtened to the body of the drum, and a like number of ſcrews to ſcrew up and down, with a key for the purpoſe. The two *drums* are kept faſt together by two ſtraps of leather, which go through two rings, and are faſtened, the one before and the other behind the pommel of the *kettle*-drummer's ſaddle. They have each a banner of ſilk or damaſk, richly embroidered with the ſovereign's arms, or of the colonel, and are fringed with ſilver or gold; and to preſerve them in bad weather, they have each a cover of leather. The drum-ſticks are of crab-tree, or other hard wood, eight or nine inches long, with two knobs on the ends, which beat the drum head, and cauſe the ſound. The *kettle-drum*, with trumpets, is the moſt martial ſound of any; each regiment of horſe has a pair.

The *kettle*-drummer rides always at the head of the ſquadrons, and his poſt is on the right when the ſquadron is drawn up.

The *kettle*-drum belonging to the royal regiment of artillery, is mounted on a ſuperb waggon, richly gilt and ornamented, and drawn by four white horſes, elegantly capariſoned, with a ſeat for the drum-major general.

KEVELS, or CHEVILS, *in a Ship*, are two pieces of timber ruiſed to the inſide of a ſhip, from whence the upper ends branch outward into arms or horns, ſerving to belay the great ropes, by which the bottoms of the main-ſail and fore-ſail are extended.

KEY, a little iron inſtrument, for the opening of locks.

L. Molinus has a treatiſe of *keys*, De Clavibus Veterum, printed at Upſal. He derives the Latin name *clavis* from the Greek κλειω, *claudo*, *I ſhut*; or from the adverb *clam*, *privately*; and adds, that the uſe of *keys* is yet unknown in ſome parts of Sweden.

The invention of *keys* is owing to one Theodore of Samos, according to Pliny, and Polydore Virgil; but this muſt be a miſtake, the uſe of *keys* having been known before the ſiege of Troy: mention even ſeems to be made of them in the nineteenth chapter of Geneſis.

Molinus is of opinion, that *keys*, at firſt, only ſerved for the untying certain knots, wherewith they anciently ſecured their doors: but the Laconic *keys*, he maintains, were ſcarly akin in uſe to our own: they conſiſted of three ſingle teeth, and made the figure of an E; of which form there are ſtill ſome to be ſeen in the cabinets of the curious.

There was alſo another *key*, called βαλαναγρα, made in the manner of a male ſcrew, which had its correſponding female in a bolt affixed to the door.

KEY is, hence, become a general name for ſeveral things ſerving to ſhut up or cloſe others.

KEY, or KEY-STONE, *of an arch, or vault*, is the laſt ſtone placed atop thereof; which, being wider and fuller at the top than bottom, wedges as it were, and binds in, all the reſt.

The *key* is different in the different orders; in the Tuſcan and Doric, it is a plain ſtone, only projecting; in the Ionic, it is cut, and waved ſomewhat after the manner of conſoles; in the Corinthian and Compoſite, it is a conſole enriched with ſculpture, foliages, &c. See *Tab. Archit. fig. 3. lit. c. fig. 50. lit. f.*

M. Belidor makes the thickneſs of the *arch-ſtones* of a bridge, one twenty-fourth part of the width of the arch; but M. Gautier, another experienced engineer, makes their length, in an arch twenty-four feet wide, two feet; in arches, forty-five, ſixty, ſeventy-five, ninety wide, three, four, five, ſix feet, reſpectively: and it is obſerved by Mr. Muller, that the thickneſs allowed by Belidor is not ſufficient to prevent the weight of the arches from cruſhing the *key-ſtones* to pieces by their preſſure againſt one another. Muller's Pract. Fortif. p. 253

The name KEY-*ſtones*, or *arch-ſtones*, is ſometimes alſo given to all the ſtones which form the ſweep of an arch, or vault—anſwering to what the French more diſtinctly call *vouſſoirs*.

KEY is alſo uſed for the eccleſiaſtical juriſdiction; particularly for the power of excommunicating, and abſolving. The Romaniſts ſay, the pope has the power of the *keys*, and can open and ſhut paradiſe as he pleaſes; grounding their opinion on that expreſſion of Jeſus Chriſt, *I will give thee the keys of the kingdom of heaven.*

In St. Gregory we read, that it was the cuſtom heretofore, for the popes to ſend a golden *key* to princes, wherein they always incloſed a little of the filings of St. Peter's chains,

chains, kept with great devotion at Rome; and that these *keys* were worn in the bosom, as being supposed to contain some wonderful virtues.

KEY, in *Poiography*, and *Steganography*, denotes the alphabet of a CIPHER; which is a secret known only to the person who writes the letter, and him who deciphers it. See ALPHABET.

Some ciphers have a single *key*, where the same characters are used throughout; in other ciphers, the characters are varied, and the *key* is double.

KEY, in *Musick*, is a certain fundamental note, or tone, to which the whole piece, be it concerto, sonata, cantata, &c. is accommodated; and with which it usually begins, but always ends.

To get an idea of the use of the *key*, it may be observed, that as in an oration there is a subject, *viz.* some principal person or thing to which the discourse is referred, and which is always to be kept in view, that nothing unnatural, and foreign to the subject may be brought in; so in every regular piece of music, there is one note, viz. the *key*, which regulates all the rest. The piece begins and ends in this; and this is, as it were, the musical subject, to which a regard must be had in all the other notes of the piece. Again, as in an oration there are several distinct articles, which refer to different subjects, yet so as they have all a visible connection with the principal subject, which regulates and influences the whole; so in music there may be various subaltern subjects, that is, various *keys*, to which the different parts of the piece may belong: but then they must be all under the influence of the first and principal *key*, and have a sensible connection with it.

To give a more distinct notion of the *key*, we must observe, that the octave contains in it the whole principles of music, both with respect to consonance or harmony, and succession or melody; and as either scale be continued to a double octave, there will, in that case, be seven different orders of the degrees of an octave, proceeding from the seven different letters, with which the terms of the scale are marked. Any given sound, therefore, i. e. a sound of any determinate pitch or tune, may be made the *key* of the piece, by applying it to the seven natural notes arising from the division of an octave, and repeating the octave above or below, at pleasure. The given note is applied as the principal note or *key* of the piece, by making frequent closes, or cadences upon it; and, in the progress of the melody, no other but those seven natural notes can be admitted, while the piece continues in that *key*, every other note being foreign to the fundamental, or *key*.

For instance, suppose a song begun in any note, and carried on upwards, or downwards, by degrees, and harmonical distances, so as never to touch any notes, but what are referable to that first note as a fundamental, i. e. are the true notes of the natural scale proceeding from the fundamental; and let the melody be so conducted through those natural notes, as to close and terminate in the fundamental, or any of its octaves above or below; that note is called the *key* of the melody, because it governs all the rest, limiting them so far, as that they must be to it, in the relation to the seven essential notes of an octave; and when any other note is brought in, it is called *going out of the key*.

From which way of speaking, viz. a song's continuing in, or going out of the *key*, it may be observed, that the whole octave, with its natural notes, come under the idea of a *key*; though the fundamental or principal note is, in a peculiar sense, called the *key*.

In which last sense of the word *key* (viz. where it is applied to one fundamental note), another note is said to be out of the *key*, when it has not the relation to that fundamental of any of the natural notes belonging to the conciunous division of the octave.

Here too it must be added, with respect to the two different divisions of the octave, that a note may belong to the same *key*, i. e. it may have a just musical relation to the same fundamental in one kind of division; and be out of the *key*, with respect to another.

Now a piece of music may be carried through several *keys*; i. e. it may be given in one *key*, and be led out of that into another, by introducing some note foreign to the first, and so on to another: but a regular piece must not only return to the first *key*, but those other *keys*, too, must have a particular connexion with the first. It may be added, that those other *keys* must be some of the natural notes of the principal *key*, though not any of them at pleasure.

As to the distinctions of *keys*, we have already observed, that to constitute any given note or sound, a *key*, or fundamental note, it must have the seven essential or natural notes added to it; out of which, or their octaves, all the notes of the piece must be taken, while it keeps within the *key*, i. e. within the government of that fundamental. It is evident, therefore, there are but two different species of *keys*, which arise according as we join the greater or less third, these being always accompanied with the sixth or seventh of the same species, the third *g*, for instance, with the sixth and seventh *g*; and the third *b* with the sixth and seventh *b*.

This distinction is expressed under the names of *sharp key*, which is that with the third *g*, &c. and the *flat key*, which is that with the third *b*, &c. whence it is plain, that how many different closes soever there be in a piece, there can be but two *keys*, if we consider the essential difference of *keys*; every *key* being either flat or sharp, and every sharp *key* being the same, as to melody, as well as every flat one.

It must be observed, however, that in common practice the *keys* are said to be different, when nothing is considered but the different tune, or pitch of the note, in which the different closes are made. In this sense, the same piece is said to be in different *keys*, according as it is begun in different notes, or degrees of tune.

To prevent any confusion which might arise, from using the same word in different senses, Mr. Malcolm proposes the word *mode* to be substituted instead of the word *key*. In the former sense; that is, where it expresses the melodious constitution of the octave, as it consists of seven essential or natural notes, besides the fundamental; and in regard there are two species of it, he proposes, that that with a third *g* be called the *greater mode*; and that with a third *b*, the *lesser mode*; appropriating the word *key* to those notes of the piece in which the cadence is made; all of which may be called *different keys*, in respect of their different degrees of tune.

To distinguish then accurately between a *mode* and a *key*, he gives us this definition; viz. an octave, with all its natural and essential degrees, is a *mode*, with respect to the constitution, or manner of dividing it; but with respect to its place in the scale of music, i. e. the degree or pitch of tune, it is a *key*; though that name is peculiarly applied to the fundamental.

Whence it follows, that the same mode may be with different *keys*; i. e. an octave of sounds may be raised in the same order, and kind of degrees, which makes the same mode, and yet be begun higher or lower; i. e. be taken at different degrees of tune, with respect to the whole, which makes different *keys*; and, *vice versâ*, that the same *key* may be with different modes. i. e. the extremes of two octaves may be in the same degree of tune, yet the division of them be different.

KEYS also denote those little pieces in the fore-part of an organ, spinett, or harpsichord; by means whereof the jacks are played, so as to strike the strings of the instrument; and wind is given to the pipes, by raising and sinking the sucker of the sound-board.

In large organs there are several sets of these *keys*; some to play the small second organ, some for the main organ, some for the trumpet, and some for the echoing trumpet. In some these are but a part that play, the rest being for ornament. There are twenty slits in large *keys*, which make the half notes.

M. Bulioutki, of Douliez, pretends to have invented a new kind of *keys*, much preferable to the common ones. With these, he says, he can express sounds, which follow each other in a continual geometrical proportion; and so can furnish all the sounds in music, and by consequence all the imaginary intervals and concords; whereas the common *keys* do but yield some of them.

KEY, in a *Naval Sense*. See KAY.

KEYS, in *Sea Language*, a name given to certain rocks lying near the surface of the water, particularly in the West *Indies*.

KEYS, a denomination given to the seeds of the ash.

KHAZINE, the grand seignior's treasury. See TREASURY, and EXCHEQUER.

Here are kept registers of receipts, accounts of provinces, in drawers, marked with the years, and the places names: here is also kept part of the emperor's wardrobe.

Every day of the divan this treasury is opened, either to take out, or put something in; and the principal officers, who have the charge of it, are all to assist at this opening. The tchaouch-bachi, in their presence, first breaks the wax wherewith the key-hole had been sealed up, and, carrying it to the grand vizir, that minister first kisses it, and then draws out of his bosom the grand seignior's gold seal. In the mean time he looks narrowly after the officer, who when he has done his business in the treasury, locks and seals up the place, and returns the seal to the vizir with the same ceremony as before.

Besides this, there are other apartments for the money, where the officers are never allowed to enter with any cloaths that have pockets in them.

KIBES. See CHILBLAIN.

KICKER *against the spurs*, in the *Manage*, See RAMINGUE.

KID, in *Zoology*, the name by which young goats are called. *See* GOAT.

KIDDERS, those that badge, or carry corn, dead victuals, or other merchandiſe, up and down to ſell: every perſon being a common badger, *kidder*, lader, or carrier, &c. ſays the ſtat. 5 Eliz. cap. 12. And they are called *kidders*, 13 Eliz. cap. 25.

KIDDLE, or KIDEL, *Kidellus*, a dam or wear in a river, with a narrow cut in it, for the laying of pots, or other engines to catch fiſh.

The word is ancient; for in Magna Charta, cap. 24. we read, *omnes kidelli deponantur per Thamefiam & Medowayam & per totam Angliam, niſi per coſteram maris.* And by king John's charter, power was granted to the city of London, *de kidellis amovendis per Thamefiam & Medowayam.* A ſurvey was ordered to be made of the weirs, mills, ſtanks, and *kidells*, in the great rivers of England, 1 Hen. IV. Fiſhermen of late corruptly call theſe dams *kettles*; and they are much uſed in Wales, and on the ſea-coaſts of Kent.

KIDDOW, in *Ornithology*, the moſt common Engliſh name of the LOMWIA, a web-footed bird, common on our ſhores, and called in different places the guillemot or guillem, and the ſea-hen, and ſkout.

KIDNAPPING, in *Law*, is the offence of ſtealing and conveying away a man, woman, or child, and at common law is puniſhable by fine, pillory, &c. Alſo if a maſter of a ſhip ſhall, during his being abroad, force any man aſhore, and wilfully leave him behind, he ſhall ſuffer three months impriſonment. 11 & 12 W. III. c. 7.

KIDNEY, *ren*, in *Anatomy*, a part of an animal, whoſe uſe is to ſeparate the urine.

The *kidneys* are two, ſituate one on each ſide; one between the liver and muſculus lumbaris, on the right ſide; the other between the ſpleen and the ſame muſcle, on the left ſide. In man, the right is lower than the left; but in quadrupeds it is uſually the contrary; they are faſtened to the loins and the diaphragm, by their exterior membrane, and to the bladder by the ureters; the right is alſo faſtened to the inteſtinum cœcum, and the left to the colon; their figure reſembles a bean, or rather a creſcent, being curve on the ſide of the vena cava, and on the outſide gibbous.

There are ordinarily but two *kidneys*, though ſometimes three have been found, and ſometimes four, and ſometimes on the other hand only one. In men they are commonly about five inches long, and three broad, and one and a half thick; their ſubſtance is compoſed of glands, and very ſmall urinary pipes, or canals; the glands form the circumference, and ſerve to ſeparate the urine; the papillæ, or urinary tubes, form the inner part; they come out of the glands, and carry the urine into a cavity in the concave part of the *kidney*, called the PELVIS; whence it paſſes through the ureters into the bladder.

The *kidneys* are covered with two membranes; they have each of them arteries and veins; the arteries come from the aorta, and the veins terminate in the cava; theſe are all called *emulgents*. They have nerves alſo, which take their origin from the plexus renalis, formed by the ramifications of the intercoſtal nerve, and the nerves of the loins.

The lymphatic veſſels of the *kidneys* appear upon blowing by the ureter into the pelvis of the *kidney*.

The *kidneys* ſecrete the urine from the blood, which, by the motion of the heart, is driven through the arteries into the emulgent arteries, and theſe carry it into the little glands; where its ſeroſity being ſeparated, it is received in at the orifices of the urinary pipes, which go from the glands to the pelvis, and thence runs by the ureters into the bladder; the blood, which could not enter the glands, is brought back by the emulgent veins. See *Tab. Anat. (Splanch.) fig. 1. litt. II. fig. 4. litt. b b, c c.*

KIDNEYS, *inflammation of the*. See NEPHRITIS.

KIDNEYS *of fiſh*. Fiſh of all kinds have *kidneys*, but they differ extremely in the ſeveral genera. All the cetaceous fiſhes, and many of the cartilaginous kinds, have two *kidneys*, as quadrupeds have. In moſt of the ſpinoſe kinds, they are found concreted into one. In the ſpinoſe fiſhes they are oblong, and extended throughout the whole length of the abdomen. In the cetaceous fiſhes they are of a roundiſh oblong figure, as in quadrupeds; and as to their ſituation, the ſpinoſe fiſh in general have them extended all along the back-bone, and the cetaceous kinds are on the contrary in the lower part of the belly; they are very long and large in the ſpinoſe kinds, and very ſmall and ſhort in the cetaceous. The urinary bladder is generally ſituated in the lower part of the abdomen in theſe creatures, and often lies upon the rectum. There are generally two ureters, by which the urine is ſecreted from the *kidneys* into it; but the urethra, through which the urine is to be diſcharged from the bladder, is leſs obvious in the ſpinoſe fiſhes. In the cetaceous kinds, it is plainly to be followed either into the vulva, or *foramen ſeminis*.

KIDNEY *beans*, in *Botany*. See *Kidney* BEANS.

KIDNEY *bean tree*. See *Liquorice* VETCH.

KIDNEY *wort*. See HERB *bennet*, and NAVEL *wort*.

KIGGELARIA, in *Botany*, a genus of the *dioecia decandria* claſs. Its characters are theſe: the male and female flowers are ſituated on different trees; the male flowers have an epalement of one leaf, cut into five concave ſegments, and five concave petals, which are ſhaped like a pitcher, each having a honey gland faſtened to the baſe, with three obtuſe coloured lobes; and have ten ſmall ſtamina; the female flowers have petals like the male, but no ſtamina; in the centre is ſituated a roundiſh germen, which becomes a rough globular fruit, with a thick cover, having one cell, filled with angular ſeeds. We have but one ſpecies of this genus, which grows naturally at the Cape of Good Hope. Miller.

KILCH, in *Ichthyology*, a name uſed by ſome for a ſpecies of fiſh of the albula kind, caught in the lakes of Germany, of a fine firm fleſh and delicate flavour, and ſeems very little, if at all, different from the FERRA.

KILDERKIN, a kind of liquid meaſure, which contains two firkins, or eighteen gallons, beer-meaſure, and ſixteen ale-meaſure.

Two *kilderkins* make a barrel, and four an hogſhead.

KILLAS, in *Natural Hiſtory*, a name given by the people who dig in the mines of Cornwall, to a kind of greyiſh white earth, which is of great hardneſs, and ſeems to approach very much to the nature of the *lapis Helmontii* of ſome kinds, only that it is ſomewhat leſs hard than that, and has nothing of the ſepta or partitions that make the character of that foſſil. This earth contains ſo great a quantity of ſpar, that it ferments with acids very ſtrongly, though that ſpar being once diſſolved, and the earthy part of the ſubſtance only left, it will no longer ferment with theſe menſtruums; whence it is evident, that its terreſtrial matter is not alkaline, though the ſpar it contains is ſo.

This is the certain character of what is called *killas* in many parts of Cornwall, where it lies in ſtrata of two, three, or more feet thick, and often beſide this is laid on each ſide of the vein of tin or other ore. But in ſome other parts of England, the miners uſe the ſame word to expreſs a kind of white, brittle, and ſhattery ſtone, ſomewhat like the flag-ſtone with which they cover houſes in Northamptonſhire, and many other counties.

KILLAS is alſo uſed as the name of a flaky ſtone of various colours, ſpangled all over with talc in ſmall flakes in the place where they uſe it. In this ſenſe they generally expreſs themſelves, when talking of the earth deſcribed above, by the phraſe *white killas*. They alſo ſometimes call this flaky ſtone by the name DELVIN.

KILLKENNY-*marble*, a fine black marble full of ſhells, and coralloide bodies, and much uſed in chimney-pieces, &c. See *Coralloide* MARBLE.

KILLOS, a name given by the miners of Cornwall to a ſtone of the ſlate kind, found in the mines there. See GROWAN.

KILLOW, or CULLOW, an Engliſh name for a black earth of a very remarkable ſtructure, ſeeming of a mixed nature between the marbles, ochres, and clay; and uſually containing a large quantity of the matter of the common vitriolic pyrites or ink-ſtone, which gives it a very ſharp unpleaſant taſte, and makes it, when thrown on the fire, emit a ſlight blue-flame of a ſulphureous ſmell, and calcine to a deep red. It is common in many parts of England, Wales, and Ireland. It is lighter than any of the other clays, though that is the genus to which it moſt properly belongs; and it is of an uneven ſurface, and ſhattery ſtructure.

KILLYTH-STALLION, in our *Old Writers*, is where lords of manors were bound by cuſtom to provide a ſtallion for the uſe of their tenants mares.

KILN, a ſtove uſed in the manufacture of various articles. A fabric formed for admitting heat, in order to dry or burn materials placed in it to undergo ſuch operations.

KILN, *brick*. See BRICK.

KILN *for drying hops*. See HOPS and OAST.

KILN, *lime*. The *kilns* uſed for chalk or ſtone, they commonly make in a large pit, which is dug either round or ſquare, according as they have convenience; and is of ſuch a ſize as will be proper for the quantities they intend to burn. They are wideſt at the top, and narrower, by degrees, as they come nearer the bottom. The inſide of this pit is lined with a wall built of lime-ſtones at the outſide, near the bottom, they have a hole, or door, by which they take out the aſhes, and above that ſome have an iron grate, which comes cloſe to the wall all about it; but others arch it over with ſtone, or large

pieces

piece of chalk; and upon this they lay a layer of ſtone, or of whatever elſe they burn in the pit; upon this they place a layer of wood, or coals, and ſo on, layer over layer, to the top of the pit; only they obſerve, that the outermoſt layer be always of the fuel, not of the ſtone. When the *kiln* is thus filled, they give fire at the hole underneath, and the lime is finiſhed in a different time, according to the nature of the ſubſtance. That made of chalk is commonly burnt into lime in twenty-four hours; but lime-ſtone generally takes ſixty hours in burning. Ten buſhels of ſea-coal, or one hundred of faggots, three feet long, will burn forty buſhels of chalk, and this will yield thirty buſhels of unſlaked lime. Where chalk is ſcarce, they work up the chalk rubbiſh into a ſort of ſtiff paſte with water, and make it into a ſort of bricks, which they dry in the air, and then burn them into lime in the common way; but this is not quite ſo good as the other. But lime taken out of the *kiln*, and mixed into a very ſoft paſte with water, and then mixed with ſand, makes a kind of mortar, very much ſuperior to the common ſort. See LIME.

KILN, *malt*. See MALT.

KILNS *for drying maddor, ſaffron*, &c. ſee the reſpective articles.

KILN *for tin-ore*. The place where the tin-ore is roaſted in order to burn away the mundic, and other ſulphureous matters that are mixed with it, is called the *tin-kiln*. This is of a very plain ſtructure; its hearth or floor is made of one large ſtone, and this is covered with another, ſupported at ſix inches height above it. The uppermoſt has a hole in the middle, through which the ore is pounced on the under one; and when it is diſtributed over it in a bed of three or four inches thick, it is burnt by means of a fire of furze-buſhes kept underneath, and communicating with the ſpace between the two ſtones by an aperture behind; the lower ſtone not reaching the wall by ſix inches.

When the ſulphur is all burnt away by the fire, and the flame is no longer blue, the whole bed of roaſted ore is thruſt off the ſtone by the rake into the aperture behind, through which it falls into the open fire. The fire is kept up with new buſhes, and there is a new bed of ore thrown in at the hole above. Thus the fire is kept up day and night, and ſupplies of freſh ore made through the hole by the black tin brought from the buddles of waſhing troughs. When the lower part of the furnace is filled up with the ore thrown into it, there is a hole behind the *kiln*, through which this ore, and the coals and aſhes, are all raked out together, and left in the open air to cool; and the whole maſs thus raked out, with ſometimes be ſeveral days in cooling, the mixture of coals among it keeping it red-hot for a conſiderable time. When it is taken away from behind the furnace, it is waſhed again before it is put into the melting furnace. It is obſerved, that the different ores require for this laſt operation a different proportion, and different ſort of fuel. The moor-tin, that is, ſuch ore as is dug up in the moory countries, melts beſt with moor-coal charred; but that dug on the hills is found to run beſt with a mixture of charcoal and peat in equal quantities. The ſtones uſed for the *kilns* are always moor-ſtone. Phil. Tranſ. N° 69.

KIMBULA, in *Zoology*, the name of a ſpecies of crocodile found in the iſland of Ceylon, and of a very beautiful variegation of colours, being mottled all over with extremely elegant black ſpots ſhining with the gloſs of black velvet.

KIN-*bote*, compenſation for the ſlaughter of a kinſman. See BOTE.

KINAKINA *aromatica*, in the *Materia Medica*, a name by which ſome authors have called the *cortex winteranus*.

KINDRED, in *Law*, are a certain body of perſons of kin, or related to each other. See ADMINISTRATION, AGNATI, COGNATI, CONSANGUINITY, and DEGREES.

KINE, in *Zoology*. See BULL and COW.

KING, a monarch, or potentate, who rules ſingly and ſovereignly over a people.

Camden derives the word from the Saxon *cyning*, which ſignifies the ſame; and that from *can, power*, or *ken, knowledge*, wherewith every monarch is ſuppoſed to be inveſted. The Latin *rex*, the Scythian *reix*, the Punic *reſch*, the Spaniſh *rey*, the French *roy*, come all, according to Poſtel, from the Hebrew ראש, *reſch, chief, head*. *Kings*, both among the ancient Greeks and Romans, were prieſts as well as princes. Virgil, ſpeaking of Anius, king of Delos, ſays,

Rex Anius, rex idem hominum, Phœbique ſacerdos.

As to the Romans, Livy and Dionyſius are expreſs; they ſay, that though Numa inſtituted a great number of orders of prieſthood, yet ſome he diſcharged himſelf, and in perſon. After the expulſion of the *kings*, they were obliged to create a *rex ſacrorum*, a *king* of the ſacrifices, for the adminiſtration of the prieſtly part of the royalty.

Lawyers ſay, the *king* of England is a mixed perſon, a prieſt as well as a prince: at his coronation he is anointed with oil, as the prieſts and *kings* of Iſrael were, to intimate, that his perſon is ſacred.

Among the Greeks, the *king* of Perſia had anciently the appellation of the *great king*; the *king* of France now has that of the *moſt Chriſtian king*, and the king of Spain has that of *catholic king*. See CATHOLIC.

The *king* of the Romans is a prince choſen by the emperor, as a coadjutor in the government of the empire.

The *kings* of England, by the Lateran council, under pope Julius II. had the title of *Chriſt anoiſſimus* conferred on them; and that of *DEFENDER of the faith* was added by pope Leo X. though it had been uſed by them ſome time before.

The title of *grace* was firſt given to our *kings* about the time of Henry IV. and that of *moſtly* firſt to Henry VIII. before which time our *kings* were called grace, highneſs, &c.

In all public inſtruments and letters, the *king* ſtyles himſelf *we*, us; though till the time of *king* John, he ſpoke in the ſingular number.

The Hungarians formerly gave the name *king* to their queen Mary, to avoid the infamy which the laws of that country caſt upon thoſe who are governed by women: accordingly, the bore the title of *king* Mary, till her marriage with Sigiſmund, at which time ſhe took the title of queen.

The laws make it *high* TREASON barely to imagine or intend the death of the *king*; and, becauſe the deſtruction of the *king* may riſque that of his great counſellors or officers, it is felony in any of the *king*'s ſervants to conſpire even that; though in other capital caſes, it is a rule, that *voluntas non reputabitur pro facto*; and an Engliſhman ſhall not, in any other caſe, be put to death, unleſs the deed follow the intent. The *king*'s office (as he promiſes at his coronation) is to preſerve the rights and privileges of the church, the prerogative of the crown, the laws and cuſtoms of the realm, &c. or, as Forteſcue has it, he is *pugnare bella populi ſui, & eos rectiſſime judicare*. See *Coronation* OATH. He acknowledges no precedence in any other prince but the emperor.

The *king* is conſidered by the laws of England as the head and ſupreme governor of the national church. 26 Hen. VIII. cap 1. 1 Eliz. cap. 1. In virtue of this authority, he convenes, prorogues, reſtrains, regulates, and diſſolves, all eccleſiaſtical ſynods or convocations.

He has the ſupreme right of patronage, called *patronage paramount*, over all the eccleſiaſtical benefices in England. He has power, by his prerogative, without any act of parliament, to make war or peace, conclude leagues and treaties, grant ſafe-conducts, give commiſſions for raiſing and regulating fleets and armies, as well as for erecting, manning, and governing forts, and other places of ſtrength, to appoint ports and havens, to erect beacons, light-houſes, and ſea-marks, to prohibit the exportation of arms or ammunition out of the kingdom, diſpoſe of magazines, caſtles, ſhips, public moneys, &c. He has the ſole power of ſending ambaſſadors to foreign ſtates, and of receiving ambaſſadors at home. He convokes, adjourns, prorogues, and diſſolves parliaments; and may refuſe his aſſent to any bill paſſed by both houſes, without giving his reaſons for it. See DOCTRINE.

He may increaſe the number of members of either houſe at pleaſure, by creating new peers, and beſtowing privileges on other towns for ſending burgeſſes to parliament. But this part of the prerogative of increaſing the number of parliament-men, in the lower houſe, ſeems to be given up by the late *kings*. The *king* is entruſted with the ſole power of conferring dignities and honours, ſo that all degrees of nobility, knighthood, and other titles, are received by immediate grant from the crown; either expreſſed in writing, by writs or letters patent, as in the creation of peers and baronets; or by corporal inveſtiture, as in the creation of a ſimple knight. And as the *king* may create new titles, ſo he may create new offices, but with this reſtriction, that he cannot create new offices with new fees annexed to them, nor annex new fees to old offices: for this would be a tax upon the ſubject, which cannot be impoſed but by act of parliament. The *king* has alſo the prerogative of conferring privileges upon private perſons; ſuch as granting place or precedence to any of his ſubjects; ſuch is alſo the power to enfranchiſe an alien, and make him a denizen. Such is likewiſe the prerogative of erecting CORPORATIONS.

The *king* is alſo the arbiter of commerce. Under this branch of the prerogative he has power to eſtabliſh public marts, or places of buying and ſelling; ſuch as markets and fairs, with the tolls belonging to them; and likewiſe to regulate weights and meaſures; to give money, which is the medium of commerce, authority, or to make it current; and the coining of money is the act

of the sovereign power, and the settling of the denomination or value for which the coin is to pass current. The *king* may also at any time decry or cry down any coin of the kingdom, and make it no longer current.

Debts due to him are always to be satisfied in the first place, in case of executorship, &c. and till his debt is discharged, he may protect the creditor from the arrests of others. He may distrain for the whole debt on a tenant that holds but part of the land; is not obliged to demand his rent as others are; may sue in what court he pleases, and distrain where he sues. In all doubtful cases, *semper præsumitur pro rege*: no statute restrains him, unless he be particularly named. In all cases where the *king* is plaintiff, his officers may enter with an arrest; and, if entrance be denied, break open a house, and seize the party; though in other cases a man's house is his castle, and has a privilege to protect him against all arrests.

He has custody of the persons and estates of idiots and lunatics; he is *ultimus hæres regni*, and to him revert all estates, when no heir appears. All treasure-trove (i. e. money, plate, or bullion, found, and the owners not known) belongs to him; so all waifs, estrays, wrecks, lands recovered from the sea, gold and silver mines, royal fishes, &c. belong to him. See REVENUE. He can unite, separate, enlarge, or contract, the limits of bishopricks, or ecclesiastical benefices, and by his letters erect new bishopricks, colleges, &c. See REGALIA.

He can dispense with the rigour of the ecclesiastical laws, except those which have been confirmed by act of parliament, or declared by the bill of rights; as, for a bastard to be a priest, for a bishop to hold a benefice in commendam, &c. He has also power to dispense with several acts of parliament, and penal statutes, by a non-obstante, where himself is alone concerned; to moderate the rigour of the law, according to equity; to pardon a man condemned by law, except in appeals of murder, and in case of impeachments by the house of commons; and to interpret by his judges, in statutes and cases not defined by law.

But though he be intrusted with the whole executive power of the law, yet he cannot sit in judgment in any court; for justice must be administered according to the powers committed and distributed to the several courts.

The law esteems him God's vicegerent on earth, and ascribes various perfections to him, not belonging to any other man. *Rex est vicarius*, says Bracton, *et minister Dei in terra. Omnis quidem sub eo est, et ipse sub nullo nisi tantum sub Deo.* He is said to have imperial dignity; and in charters before the Conquest is frequently stiled *basileus* and *imperator*, the titles respectively assumed by the emperors of the East and West. His realm is declared to be an empire, and his crown imperial, by many acts of parliaments, particularly the statutes 24 Hen. VIII. cap. 12. and 25 Hen. VIII. cap. 28. which at the same time declare the *king* to be the supreme head of the realm in matters both civil and ecclesiastical, and consequently inferior to no man upon earth, dependent on no man, and accountable to no man. See also 24 Geo. II. cap. 24. 5 Geo. III. cap. 27. Hence it is that no suit or action can be brought against the *king*, even in civil matters; because no court can have jurisdiction over him. The law also ascribes to the *king*, in his political capacity, absolute perfection. The *king* can do no wrong; by which ancient and fundamental maxim we are not to understand, that every transaction of government is of course just and lawful, but that whatever is exceptionable in the conduct of public affairs is not to be imputed to the *king*, nor is he answerable for it personally to his people; and farther, that the prerogative of the crown extends not to do any injury: it is created for the benefit of the people, and, therefore, cannot be exerted to their prejudice. In the *king* there is no folly or weakness; no injustice or error; and, therefore, if the crown should be induced to make an improper grant of any franchise or privilege, the law declares that the *king* was deceived in his grant, and thereupon such grant is rendered void, merely upon the foundation of fraud and deception, either by or upon those agents whom the crown had employed. Yet, notwithstanding this personal perfection which the law ascribes to the sovereign, the constitution has allowed a latitude of supposing the contrary, in respect of both houses of parliament; each of which, in its turn, hath exerted the right of remonstrating and complaining to the *king* even of those acts of royalty, which are most properly his own; such as messages signed by himself, and speeches delivered from the throne; nevertheless, for the sake of freedom of debate, these acts of state are usually supposed to proceed from the advice of the administration. In the *king* likewise there can be no negligence or *laches*, and, therefore, no delay will bar his right: *nullum tempus occurrit regi*. In the *king* also there can be no infancy, stain, or corruption of blood. By his crown he is, *ipso facto*, cleared of all attainder; no non-age or minority are allowed to him; and his very grants of lands, though held in his natural capacity, cannot be avoided by non-age. Nay more, the law ascribes a kind of perpetuity, or immortality to him: *rex Angliæ non moritur*. His death is termed his *demise*, because the crown is thereby demised to his heir.

He is said not to be liable to death, as being a corporation of himself, that lives for ever. There is no interregnum, but the moment one *king* dies, his heir is *king*, fully and absolutely, without any coronation, ceremony, &c. To these, it may be added, that the law attributes a kind of ubiquity to the *king*; he is in a manner every where, in all courts of judicature, which he alone has the right of erecting, and therefore cannot be nonsuited. The power of issuing proclamations is vested in the *king* alone, considered as the fountain of justice.

Some things, however, there are which the *king* cannot do; viz. he cannot divest himself, or successors, of any part of his regal PREROGATIVE, authority, &c. There are several things also which he cannot do *salvo jure, salvo juramento, & salva conscientia sua*: in particular, there are two things which he cannot do without the consent of parliament; viz. make new laws, or raise new taxes.

KING, *champion of the.* See CHAMPION.

KING, *charters of the.* See CHARTER.

KING, *committee of the.* See COMMITTEE.

KING, *peace of the.* See PEACE.

KING, *quarantain of the.* See QUARANTAIN.

KING, *revenue of the.* See REVENUE.

KING, *succession of the.* See CROWN, *right of.*

KING, *tenant of the.* See TENANT.

KING, *widow of the.* See WIDOW.

KING *of the Romans.* See ROMANS.

KING, among *Hebrew Grammarians*, is an appellation given to a species of accents answering to our colon. See ACCENT.

KING *of the mullets.* See MULLUS *imberbis*.

KING *of the quails.* See DAKER *hen*.

KING *of the sacrifices, rex sacrificulus*, or *sacrorum*, was a title of an ancient priest, or minister of religion, at Rome; who was superior to the flamen dialis, but inferior to the pontifex maximus.

He was created at the comitia centuriata, or assembly of the centuries, and was at first chosen out of the number of the patricians. He could not, during his office, hold any magistracy, nor harangue the people. He presided at all the sacrifices, proclaimed the feasts, &c.

His wife bore the title of *queen of the sacrifices, regina sacrorum*; and had herself a part in the sacred ceremonies.

KING *at arms, or of arms*, is an officer of great antiquity, and anciently he was of great authority; his business is to direct the heralds, preside at their chapters, and have the jurisdiction of armory.

The origin of this title is doubtful. Some of the French writers imagine, that it was given to heralds, because they attended upon and regulated military ceremonies. Others attribute to them the style of *kings*, because they governed and presided in ceremonies of tournaments, in like manner as the master of the ceremonies at Athens was styled *βασιλευς*. Others again ascribe the title to them, because in alliguing arms, as expressions of honour to any person, they resembled the kingly prerogative. But this supposes that the custom of granting arms by the *kings* of heralds is as ancient as their titles; whereas Mr. Edmondson observes, in his Complete Body of Heraldry, that it doth not any where appear that these *kings* had anciently the addition *armorum* given to them, they being then called, as they truly were, *reges heraldorum*; which for the most part continued till about the reign of Henry IV. when they began to be entitled *reges armorum*, although their primitive appellation was also used for some ages. The latter title of *reges armorum* was attributed to them before such time as those officers made any grant of arms.

In England we have three *kings* of arms, viz. Garter, Clarencieux, and Norroy.

Garter, principal KING *at arms.* See GARTER.

The two last are also called *provincial heralds*, because they divide the kingdom between them into two provinces.

These, by charter, have power to visit noblemen's families, to set down their pedigrees, distinguish their arms, appoint persons their arms, and, with *Garter*, to direct the other heralds.

Anciently the *kings at arms* were created, and solemnly crowned, by the *kings* of England themselves; but of later days the earl marshal has a special commission, at every creation, to personate the *king*.

To these may be added, *Lyon* KING *at arms*, for Scotland, who is the second *king at arms* for Great Britain; the

he is invested and crowned with great solemnity. To him belong the publishing the *king's* proclamations, marshalling funerals, reversing arms, &c. And also Ulster *king of arms* in Ireland. See COLLEGE *of Heralds.*

KING's *bench.* See COURT *of king's bench.*

KING's *evil.* See EVIL.

KING's *exchange.* See EXCHANGE.

KING's *houshold.* See HOUSHOLD, GREENCLOTH, COFFERER, and REVENUE.

KING's *library.* See LIBRARY.

KING's *palace.* The limits of the *king's* palace at Westminster extend from Charing-cross to Westminster-hall, and shall have such privileges as the ancient palaces. 28 Hen. VIII. If any person shall strike another in the *king's* palace, he shall have his right-hand cut off, be imprisoned during life, and also be fined. 32 Hen. VIII. cap. 12.

KING's *prerogative.* See PREROGATIVE, and KING.

KING's *privy council.* See PRIVY-*council.*

KING's *silver*, the money due to the king in the court of common pleas, *pro licentia concordandi*, in respect of a licence there granted to any man for levying a fine of lands, or tenements, to another person. See CLERK.

KING's *spear*, *asphodelus*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the flower has no empalement; it is of one leaf, cut into six parts, which spread open; at the bottom is inserted a globular nectarium, having six valves, and it has six stamina, which are inserted in the valves of the nectarium; between the nectarium is placed a globular germen, which becomes a fleshy seed-vessel, having three cells filled with triangular seeds. There are six species.

Linnæus mentions only three species.

The several sorts of this plant all flourish very well in any soil that is not too wet, which is subject to rot the roots in winter; and the way to increase them, is by parting their roots in August, before they shoot up their fresh green leaves. They may also be raised from seeds sown in August, and the August following the plants produced from these may be transplanted into beds, and will produce flowers the second year. They must not be planted in small borders, among tender flowers, for they will draw away all the nourishment, and starve every thing else. Miller.

The roots of asphodel are of an acrimonious taste, and heating quality; being drank, they promote urine, and the menses; and the weight of a dram taken in wine, is used with success in pains in the side, coughs, convulsions, and ruptures. They are good against bites of serpents, and make a good cataplasm for foul spreading ulcers, inflammations, &c. The ashes of the burnt root, rubbed on an alopecia, cause new hair to spring.

KING's *thanes.* See THANES.

KING's *war.* See WAR.

KING's *wardrobe.* See WARDROBE.

KING-*fish.* See OPAH.

KING-*fisher*, *ispida*, the *alcedo ispida* of Linnæus, in *Ornithology*, a very beautiful bird frequenting waters, and feeding on fish; it builds in deep holes in the banks of rivers, and lays five, or according to some, nine eggs; it much approaches to the picus or wood-pecker, in many things, but wants its great character, which is the having two toes behind; the legs of this bird are very short, and are black before, and red behind; its colours, particularly its green and blue, which are its general ones, are extremely bright and beautiful; it takes its prey after the manner of the osprey, balancing itself at a certain distance over the water for a considerable space, then darting below the surface, brings up the prey in its feet. While it remains suspended in the air, in a bright day, the plumage exhibits a most beautiful variety of very dazzling and brilliant colours. This bird was called *halcyon* by the ancients. Aristotle has described the bird and its nest, which, according to him, resembled those concretions that are formed by the sea-water, and fashioned in the shape of a long necked gourd, hollow within, but so narrow at the entrance, that if it overset, the water could not enter. This nest was called *halcyonium*, and had medical virtues ascribed to it. This nest was a floating one, and therefore it was necessary for the poets who have described it to place it in a tranquil sea, and to supply the bird with charms to allay the fury of a turbulent element during its incubation; for it had, at that season, power over the seas and winds. During the days of this bird's incubation, in the depth of winter, the mariner might sail in full security; and, therefore, they were called HALCYON *days.* See *Tab.* III. *of Birds*, N° 27.

KING-*piece*, in any buildings, is a piece of timber standing upright in the middle, between two principal rafters, and having struts or braces going from it to the middle of each rafter.

KINGDOM, among *Chemists*, is a term which they apply to each of the three orders or classes of natural bodies; *animal*, *vegetable*, and *mineral.*

KINGS, *books of*, two canonical books of the Old Testament, so called, because they contain the history of the *kings* of Israel and Judah, from the beginning of the reign of Solomon, down to the Babylonish captivity, for the space of near six hundred years. The first book of *Kings* contains the latter part of the life of David, and his death; the flourishing state of the Israelites under Solomon, his building and dedicating the temple of Jerusalem, his shameful defection from the true religion, and the sudden decay of the Jewish nation after his death, when it was divided into two kingdoms; the rest of the book is taken up in relating the acts of four *kings* of Judah, and eight of Israel. The second book, which is a continuation of the same history, is a relation of the memorable acts of sixteen *kings* of Judah, and twelve of Israel, and the end of both kingdoms, by the carrying off the ten tribes captive into Assyria by Salmanassar, and the other two into Babylon by Nebuchadnezzar.

It is probable that these books were composed by EZRA, who extracted them out of the public records, which were kept of what passed in that nation.

KINK-*cough.* See CHIN-*cough.*

KINKS, in the *Sea Language.* When ropes are new, or too hard laid, they are apt in foldings to make turns, which are called *kinks.*

KINNOR, in the *Jewish Antiquities.* See CINYRA, and CHINNOR.

KINTAL, or QUINTAL, a weight of one hundred pounds, more or less, according to the different usage of divers nations.

The *kintal* of Smyrna is 123 pounds 3 ounces 9 drachms, or 120 pounds 7 ounces 12 drachms; but that of Aleppo is 465 pounds 11 ounces 15 drachms.

KIPE, a kind of osier basket, wide in the middle, and narrow at both ends; used for taking fish.

KIPE is also a game, which consists in throwing something into a hole, called the *kipe*-hole.

KIPPER. See *Salmon* FISHERY.

KIPPER-TIME, a space of time between the festival of the finding of the Holy Cross, May the *third*, and Twelfth-day, during which, salmon-fishing in the river Thames, from Gravesend to Henley, is forbidden by Rot. Parl. 50 Edw. III.

KIRK-MOTE, a synod. See SYNOD.

Sometimes the word is also taken for a meeting in the church, or vestry. See MOTE.

KIRK-SESSIONS, the name of a petty ecclesiastical judicatory in Scotland. Each parish, according to its extent, is divided into several particular districts, every one of which has its own elder and deacon to oversee it. A consistory of the ministers, elders, and deacons of a parish, form a *kirk-session.*

These meet once a week, the minister being their moderator, but without a negative voice. It regulates matters relating to public worship, elections, catechizing, visitations, &c. It judges in matters of less scandal; but greater, as adultery, are left to the presbytery; and in all cases an appeal lies from it to the presbytery.

KIRTLE, a term used for a short jacket; also for a quantity of flax about a hundred weight.

KIS, in *Natural History*, a name given by some people to the common pyrites; and by others to a peculiar kind of it, containing copper, and a small quantity of silver.

KISSINA, in *Botany*, a name by which some authors have called the tree, whose wood is the *agallochum*, or lignum-aloes of the shops.

KIST, a word used by Paracelsus as the name of a weight, equal to fourteen grains.

KIT, in *Music*, the name of a small violin of such form and dimension as to be capable of being carried in a case or sheath in the pocket. Its length, measuring from the extremities, is about sixteen inches, and that of the bow about seventeen. Small as this instrument is, its powers are coextensive with those of the violin.

KITCHEN, a room appropriated to the dressing of meat, and furnished with suitable accommodations and utensils for that purpose. See BUILDING.

The *kitchen* in the king's household is under the direction and management of a clerk-comptroller, who has a salary of 500 l. a year, subordinate clerk at 250 l. a year, first clerk at 150 l. a year, junior clerks, two master-cooks, the salary of the first being 237 l. 10 s. a year, and of the second 217 l. 10 s. a year, yeomen, grooms, &c.

KITCHEN-*Garden.* See GARDEN.

KITE, *falco milvus* of Linnæus, in *Ornithology*, the English name of a bird of the hawk-kind, with a brown body, and a white head, sometimes marked with oblong streaks of black; its tail is forked, and of a tawny red, and the wings are immoderately

immoderately long and large, measuring near three times the length of the body; the coverts of the wings are varied with tawny black and white; the thighs are covered with very long feathers; and the legs are yellow and strong. The *kite* generally breeds in large forests, or woody mountainous countries: it lays two or at most three eggs. Its motion in the air distinguishes it from all other birds; being so smooth and even as to be scarce perceptible: Sometimes it will remain quite motionless for a long while: at other times, glide through the sky, without the least apparent action of its wings, from whence it derived the old name *glead*, of the Saxon *Glida*. Lord Bacon observes, that when *kites* fly high, it portends fair and dry weather. Pliny thinks that the invention of the rudder arose from the observation made of the various motions of the tail, when the *kite* was steering through the air. Lib. x. c. 10.

It remains with us the whole year; but in many other countries is a bird of passage.

The whole bird is of use in medicine. The ashes of the bird burnt, are said to be effectual in the gout and epilepsy, being taken inwardly: the same is said of the head and liver when burnt; and the latter also is an ingredient in ophthalmic medicines: the blood mixed with nettles and applied, is said to give relief under the gout: the gall enters the composition of collyria for the eyes; and the fat is used to anoint parts pained with the gout.

KITE, in *Falconry*. See CONDUCTOR.

KITTIWAKE, in *Ornithology*, a species of the GULL kind, being the *larus rissa* of Linnæus: the head, neck, belly and tail are of a snowy whiteness; behind each ear is sometimes a dusky spot; the back and wings are grey; the bill is yellow, tinged with green; the legs are dusky, and have a small knob instead of the back toe. This bird inhabits the romantic cliffs of Flamborough-head, the Bass-isle, the rocks near the castle of Slains in the county of Aberdeen, and Pittenhorn-isle. The young of these birds are a favourite dish before dinner, for whetting the appetite, in North Britain, but they have a rank taste and smell. Pennant.

KIZILBASCH, or KAZELBASCH, a Turkish term signifying *red-head*: applied by way of obloquy to the Persians, ever since Ishmael Sophi, founder of the family last reigning in Persia, who ordered his soldiers to wear a red cap, round which is a scarf or turban with a dozen plaits in it, in memory of the twelve imams, successors of Ali, from whom he pretended to descend.

Vigenere writes the word *kezelbash*, and adds, that, according to the vulgar interpretation among the Persians, the twelve plaits signify the twelve sacraments of their law. But not contented with this, he looks out for another original, and tells us there is a mystery in it, derived from the ancient paganism, when the Persians adored fire, whose heat is denoted by the red colour, which in some measure symbolizes with the sun, held by them in the highest veneration. He adds, that the twelve plaits shew the twelve months of the year, and the twelve signs in which that luminary performs his course.

KLEINIA, in *Botany*. See *Foreign* COLTSFOOT.

KLEINHOVIA, in *Botany*, a genus of the *gynandria decandria* class: the characters of which are, that it is monogynous; the calyx is five-leaved; the petals are five; the nectarium is campanulated, pedunculated and staminiferous; the fruit is an inflated capsule, containing five grains. There is only one species.

KLIMIA, or CLIMIA, in the *Materia Medica*, the name given by the Arabian writers to the *lapis calaminaris*. Avicenna and Serapio never call it by any other name. Some pronounce the word *calimia*. Hence the modern Greeks have formed their *calimia*, which is the name of the same substance; and our *calaminaris* is evidently deduced from the same original.

KLINKERS, in *Fortification*, a sort of small gates made through palisadoes, for sallies.

KLIP-*fish*, in *Ichthyology*, a name by some authors supposed to mean the *lupus piscis*, or wolf-fish; and by others, the common cod fish.

Of the former opinion is Fabricius, who supposes the lupus so called, because it is able to climb up rocks, or generally lies hid among rocks; the word *klip*, in the German signifying a *rock*. Of the other is Schonefeldt, who supposes the cod has its name of *klip-fish*, or rock-fish, from its being usually dried upon the rocks.

KLIP-*fish*, is also a name by which the Dutch in the East-Indies call a flat fish, caught frequently on those shores, and sometimes called also *soldatus piscis*, or the soldier's fish. It somewhat resembles the bream in shape. Its general size is about six or seven inches in length, and it is of a very white and silvery hue. It differs very greatly, however, from the bream in many particulars. The nerves of its back-fin are prickly as in the pearch; its tail is pointed, not forked; and the irises of its eyes are yellow. It is one of the finest fish of the East-Indies. Its flesh is very firm, and falls into large pieces, when dressed, like that of the cod, and is very well tasted.

KNAG, a term used by country people for a knot in wood; also for the branches which grow out in the hart's horn, near the forehead.

KNAPSACK, in *Military Language*, is a rough leather bag, which a soldier carries on his back, containing all his necessaries. Square *knapsacks* are most convenient, and should be made with a division to hold the shoe-blacking-balls, and brushes, separate from the linen. White goat skins are the best.

KNAPWEED, *jacea*, in *Botany*, see CENTAURY.

KNAVE, an old appellation for a man-servant, and so used in 14 E. III. stat. 1. cap. 3.

The word is formed from the Saxon *cnapa*, or Flemish *knape*, which signify the same.

KNAVE also signifies a male-child or boy: in which sense *knave-child* has been frequently used, in contradistinction to a *girl*; and in this sense Wickliff uses the word in his translation of Exod. ii. 6. and other places of the Bible. In the old Saxon translation of Mat. xviii. 6. *Pær wære gaet in cone gardstenn*, was turned *Myn knapa*.

KNAVE has sometimes also been used as an addition; as William Cowper de Denbigh, *knave*, &c. It is a common opinion, that Rom. i. 1. was translated, *Paul a knave of Jesus Christ*. This mistake was occasioned by a Bible in the duke of Lauderdale's library, where the word *knave* is inserted in less characters than the others, and a nature might easily be discerned.

KNAVE-*line*, in a *Ship*, a rope fastened to the cross-trees, under the main or fore-top, whence it comes down by the ties to the yard-head, and there it is reeved through a piece of wood of about two feet long, and so is brought to the ship's side, and there haled up taught to the rails.

KNAUTIA, in *Botany*, a genus of the *tetrandria monogynia* class. Its characters are these: it has several flosculæ flowers, included in one common cylindrical empalement, which have their petals ranged so as to appear like a regular flower, but each separate flosculæ is irregular; in the bottom of each flower is situated the germen, attended by four stamina; which germen changes to a single, oblong, naked, seed. Miller mentions one species, which is nearly of a kin to the scabious; but Linnæus two.

KNAWEL, in *Botany*. See SELERANTHUS.

KNECK, in the *Sea Language*, the twisting of a rope or cable, as it is veering out.

KNEE, *genu*, in *Anatomy*, the articulation of the thigh and leg-bones. See FEMUR and TIBIA.

The mucilaginous glands of the *knee*, which lie near the edges of the patella, are very remarkable; they are disposed in fringes, and supported by a great quantity of fatty matter, which in some measure makes one mass with them. This common mass is contained within the capsular ligament, and on the side of the joint is covered by a very fine membrane, which likewise lines the inner surface of the ligament. The glandulous substance is easily distinguished from the fat by the reddish colour of the capillary vessels, which surround the glands. The superior portion of this mass is, as it were, supported by a small ligament, fixed in the anterior part of the great common notch of the condyles of the os femoris, and which from thence runs to the upper part of the patella. There are also other mucilaginous glands, both above and below the edges of the semilunar cartilages, and likewise in the *knee*: some of these serve for the joint, and the others for the crucial ligaments. These last lie in folds formed by the internal membrane of the capsular ligament, which give particular coverings to the crucial ligaments, and to the other bundles of ligamentary fibres near them. Winslow.

KNEE, *Mumps of the*. See DROPSY.

KNEE, *luxated*. A luxation of the *knee* is a receding of the tibia from under the femur. The leg is sometimes thus luxated from the back of the thigh-bone on the outside, sometimes on the inside, and sometimes backward, but very rarely or never forward; unless it be forcibly driven with great violence that way; for the patella is bound against the articulation forwards, by the strong tensions of the muscles which extend the leg; nor is it indeed easy for the bones of the leg to be wholly displaced from that of the thigh, so as to make a perfect luxation of the *knee*, by reason of the great strength of the ligaments, and the two deep sinuses, which receive the head of the thigh bone, unless those strong ligaments should happen to be broken asunder at the same time. This is the reason also why people, who suffer a perfect luxation of the *knee*, are generally tortured with the most violent and excruciating pains, and convulsions; and if they escape the mischiefs usually attending such symptoms, they are generally troubled afterward with a lameness and

ſtiffneſs of the joint; but ſlight or imperfect luxations of this joint are uſually very ſpeedily and eaſily cured. The patient in this caſe is to be ſeated on a bed, bench, or table, and one aſſiſtant is to hold the thigh firmly above the knee, and another ſtrongly to extend the leg, while the ſurgeon replaces the bones by his hands and *knee*, in their natural ſituation. If the hands and ſlings are not ſufficient, in this caſe, to make a proper extenſion, recourſe muſt be had to the pulſies, generally uſed on ſuch occaſions: but in children and young perſons, great care muſt be taken not to make the extenſion to violent, as to ſeparate the epiphyſes from the bones, to which they are, in ſuch ſubjects, not yet firmly united. After the luxation is properly reduced, the *knee* is to be bound up with a proper bandage, and placed in a frame or caſe, ſo as to be kept at reſt for a proper time. Heiſter, p. 172.

KNEE-*Pan*. See PATELLA.

KNEE, in the *Manage*, is the joint of the fore quarters, that joins the fore thigh to the ſhank.

KNEES, in a *Ship*, thoſe crooked pieces of timber, bowed like a *knee*, that bind the beams and ſtuttocks together, being bolted faſt into them both. Some of theſe ſtand right up and down, ſome along-ſhip. They are uſed about all the decks; ſome hewed to that form, and others naturally ſo, which are certainly the beſt for ſervice. See CARLINE.

KNEE *of the head*, in a *Ship*, a large flat piece of timber, fixed edgeways upon the fore-part of a ſhip's ſtem, and ſupporting the ornamental-figure or image, placed under the bowſprit; it is the ſame with the *cut-water*.

KNEE-*timber*, in a *Ship*, the ſame with the *cut-water*, which is called the *knee of the head*.

KNEE *holm*, or KNEE *holly*. See BUTCHER'S *Broom*.

KNEELING. See GENUFLEXION.

KNEVELS, in a *Ship*. See KEVELS.

KNIFE is a well known inſtrument made for cutting, and adapted in form to the uſes for which it is deſigned.

Knives are ſaid to have been firſt made in England in 1563, by one Matthews, on Fleet bridge, London. Anderſ. Hiſt. Com. vol. ii. p. 402.

Surgeons have various ſorts of *knives*. See BISTOURY and *Tab. Surgery*, *Fig.* 4.—8.

KNIGHT, *Eques*, among the *Romans*, was the ſecond degree of the nobility, following immediately that of the ſenators.

At the time of building the city of Rome, the whole army of Romulus conſiſted of three thouſand foot, and three hundred horſe, which three hundred horſe were the original of the Roman *equites*, or *knights*. Theſe made the ſecond order that had places in the ſenate.

Manutius and Sigonius are of opinion, that beſide the equeſtrian order, and thoſe *knights* immediately below the ſenators, Romulus inſtituted a military order, whereof the Roman cavalry was compoſed. But no ancient author takes notice of any order of knighthood inſtituted on purpoſe for the war, nor any other *knights* but thoſe three hundred, which, as we have obſerved, were the firſt foundation of the equeſtrian order.

The *knights* had horſes kept for them at the public charge; but when they were admitted among the ſenators, they reſigned that privilege: to be a *knight*, it was neceſſary they ſhould have a certain revenue, that their poverty might not diſgrace the order; and when they failed of the preſcribed revenue, they were expunged out of the liſt of *knights*, and thruſt down among the plebeians. Ten thouſand crowns are computed to have been the revenue required.

The *knights* grew ſo very powerful, that they became a balance between the power of the ſenate and the people. They neglected the exerciſes of war, and betook themſelves principally to civil employments in Rome; inſomuch that Pliny obſerves, in his time, they had no longer a horſe kept at the public expence.

Some ſay, that the order of *knights*, as diſtinct from the people, did not begin before the time of the Gracchi; others ſay the privilege was then firſt granted them, that no judge ſhould be choſen, but out of their order: ſome time after which they admitted them into the ſenate. This, however, is certain, it was only from that time that a certain revenue was neceſſary, and that this intitled them to the knighthood, without being deſcended from ancient *knights*.

KNIGHT, in a more modern ſenſe, properly ſignifies a perſon, who, for his virtue and martial proweſs, is, by the king, raiſed above the rank of gentlemen, into a higher claſs of dignity and honour.

The word *knight*, in its original German, *knecht*, ſignifies a *ſervant*; and has ſince been uſed for a ſoldier, or man of war. We have but one inſtance among us where *knight* is uſed in the firſt ſenſe, and that is in *knight of the ſhire*, who properly *ſerves* in parliament for ſuch a county. In the Latin, French, Spaniſh, Italian, and Dutch languages, *knight* is expreſſed by a word which properly ſignifies a *horſeman*, as being uſually employed on horſeback. Indeed our common law calls them *milites*, *ſoldiers*, becauſe they uſually held lands in *knight* ſervice; to ſerve the king as ſoldiers in his wars; in which ſenſe the word *miles* was uſed *pro vaſſallo*.

Knighthood was the firſt degree of honour in the ancient armies, and was uſually conferred with a great deal of ceremony on thoſe who had diſtinguiſhed themſelves by ſome notable exploit in arms. They were originally ſaid to be adopted, *adoptabantur in militiam*, which we now call *dubbed*; as being ſuppoſed, in ſome meaſure, the ſons of him who knighted them.

The ceremonies at the creation of a *knight* have been various. The principal were a box on the ear, and a ſtroke with a ſword on the ſhoulder. Then they put on him a ſhoulder-belt, gilt ſword, ſpurs, and the other military accoutrements; after which, being armed as a *knight*, he was led in great pomp to the church.

The manner of making a *knight* with us, is deſcribed by Camden in a few words: *Qui equeſtrem dignitatem ſuſcipit, flexis genibus leviter in humero percutitur: principis his verbis Gallice effatur*: Sus vel ſois chevalier au nom de Dieu, *ſurge tu es eques in nomine Dei*. This is meant of *knights-bachelors*, which are the loweſt, though the moſt ancient order of knighthood among us; for we have an inſtance of king Alfred's conferring this order on his ſon Athelſtan. Will. Malmſb. lib. ii.

Knights grew ſo very numerous, that the dignity became of much leſs repute. Charles V. is ſaid to have made five hundred in a ſingle day: on which account, therefore, new orders of knighthood were inſtituted, in order to diſtinguiſh the more deſerving from the croud. For the ſeveral kinds of *knights* among us, ſee BACHELOR, BANNERET, BARONET, BATH, GARTER, &c.

KNIGHT is alſo underſtood of a perſon admitted into any order, either purely military, or military and religious, inſtituted by ſome king or prince, with certain marks and tokens of honour and diſtinction.

Such are the *knights of the Garter*, *of the Elephant*, *of the Holy Ghoſt*, *of Malta*, &c. All which ſee under GARTER, ELEPHANT, &c.

KNIGHTHOOD, a military order, or honour; or a mark or degree of ancient nobility, or reward of perſonal virtue and merit.

There are four kinds of *knighthood*; *military*, *regular*, *honorary*, and *ſocial*.

KNIGHTHOOD, *Military*, is that of the ancient knights, who acquired it by high feats of arms.

Theſe are called *milites*, in ancient charters and titles, by which they were diſtinguiſhed from mere *bachelors*, &c. Theſe knights were gilt with a ſword, and a pair of gilt ſpurs; whence they were called *equites aurati*.

Knighthood is not hereditary, but acquired. It does not come into the world with a man like nobility; nor can it be revoked. The ſons of kings, and kings themſelves, with all other ſovereigns, heretofore had *knighthood* conferred on them as a mark of honour. They were uſually knighted at their baptiſm or marriage, at their coronation, before or after a battle, &c.

KNIGHTHOOD, *Regular*, is applied to all military orders, which profeſs to wear ſome particular habit, to bear arms againſt the infidels, to ſuccour and aſſiſt pilgrims in their paſſage to the Holy Land, and to ſerve in hoſpitals where they ſhould be received; ſuch were the knights Templars, and ſuch ſtill are the knights of Malta, &c.

KNIGHTHOOD, *Honorary*, is that which princes confer on other princes, and even on their own great miniſters and favourites; ſuch are knights of the Garter, St. Michael, &c.

KNIGHTHOOD, *Social*, is that which is not fixed, nor confirmed by any formal inſtitution, nor regulated by any laſting ſtatutes; of which kind there have many orders been erected on occaſion of factions, of tilts and tournaments, maſquerades, and the like.

The abbot Bernardo Juſtiniani, at the beginning of his hiſtory of *knighthood*, gives us a complete catalogue of the ſeveral orders: according to this computation, they are in number ninety-two. Favin has given us two volumes of them under the title of Theatre d'Honneur & de Chevalerie. Menenius has publiſhed Deſiciæ Equeſtrium Ordinum, and Andr. Mendo has written de Ordinibus Militaribus. Beloi has traced the original, and Gelot, in his Armorial Index, has given us their inſtitutions.

To theſe may be added, Father Meneſtrier de la Chevaleric Ancienne & Moderne, Michiell's Teſoro Militale, Caramuel's Theologia Regolare, Miræus's Origines Equeſtrium ſive Militarium Ordinum: but above all, Juſtiniani's Hiſtorie Chronologiche dell' Origine de gl' Ordine Militari, e di tutte le Religione Cavalereſche: the

edition which is fuller, is that of Venice in 1692, in two vols. fol.

KNIGHT *Marſhall*. See MARSHALL.

KNIGHTS *of St. Ampulla*. See AMPULLA.

KNIGHTS *of Annunciata*. See ANNUNCIATA.

KNIGHTS *of St. Anthony*. See ANTHONY.

KNIGHTS *of St. Bridget*. See BRIGIANI.

KNIGHTS *of St. Catharine of Mount Sinai*. See CATHARINE.

KNIGHTS *of the Chapel*. See CHAPEL.

KNIGHTS *of Chriſt*. See CHRIST.

KNIGHTS *of the Collar*. See COLLAR.

KNIGHTS *of the Dragon*. See DRAGON.

KNIGHTS *of the Ermine*. See ERMINE.

KNIGHTS-*Errant*, a pretended order of chivalry, whereof ample mention is made in the old romances.

They were a kind of heroes, who travelled the world in ſearch of adventures, redreſſing wrongs, reſcuing damſels, and taking all occaſions of ſignalizing their proweſs. This romantic bravery of the old *knights* was heretofore the chimera of the Spaniards; among whom there was no cavalier but had his miſtreſs, whoſe eſteem he was to gain by ſome heroic action. The duke of Alva, notwithſtanding his age and gravity, is ſaid to have vowed the conqueſt of Portugal to a young lady.

KNIGHTS *of St. George*. See GEORGE.

KNIGHTS *Hoſpitalers*. See HOSPITALERS and MALTA.

KNIGHTS *of St. Louis*. See LOUIS.

KNIGHTS *of Malta*. See MALTA.

KNIGHTS *of St. Mark*. See St. MARK.

KNIGHTS *of Mary*. See MARY.

KNIGHTS *of the Mine*. See MINE.

KNIGHTS *of Mount Carmel*. See CARMEL.

KNIGHTS *Rad*. See RAD.

KNIGHTS *of the Round Table*. See TABLE.

KNIGHTS *of the Temple*. See TEMPLARS.

KNIGHTS *Teutonic*. See TEUTONIC.

KNIGHTS *of the Thiſtle*. See THISTLE.

KNIGHTS *of the Shire*, or KNIGHTS *of Parliament*, are two gentlemen of worth, choſen on the king's writ in pleno comitatu, by ſuch of the freeholders of every county as have the value of 40s. per ann. within the county, clear of all taxes and deductions except parliamentary and parochial taxes, to repreſent ſuch county in parliament.

This qualification of electors for *knights* of the ſhire or county members, is ſettled by ſtat. 8 Hen. VI. c. 7. and 10 Hen. VI. c. 2. According to the eſtimate of biſhop Fleetwood in his Chronicon Preciouſum, 40s. in the reign of Henry VI. was equal to 12*l. per annum* in the reign of Queen Anne; and as the value of money has been lowered ſince, Judge Blackſtone concludes that 12*l.* in the biſhop's days muſt have been equivalent to 20*l.* at preſent. The other qualifications of the electors for counties in England and Wales, collected from ſtatutes are; that no perſon under twenty-one years of age ſhall be capable of voting; nor any perſon convicted of perjury or ſubornation of perjury; that no perſon ſhall vote in right of any freehold granted to him fraudulently to qualify him to vote: that every voter ſhall have been in the actual poſſeſſion or receipt of the profits of his freehold to his own uſe for twelve calendar months before, except it came to him by deſcent, marriage, marriage ſettlement, will, or promotion to a benefice or office: that no perſon ſhall vote in reſpect of an annuity or rent-charge, unleſs regiſtered with the clerk of the peace twelve calendar months before: that in mortgaged or truſt eſtates, the perſon in poſſeſſion ſhall have the vote: that only one perſon ſhall be admitted to vote for any one houſe or tenement, to prevent the ſplitting of freeholds: that no eſtate ſhall qualify a voter, unleſs the eſtate has been aſſeſſed to ſome land-tax aid, at leaſt twelve months before the election: and that no tenant by copy of court-roll ſhall be permitted to vote as freeholder. 7 and 8 W. III. c. 25. 10 Ann. c. 23. 2 Geo. II. c. 21. 10 Geo. II. c. 18. 31 Geo. II. c. 14. 3 Geo. III. c. 24.

Theſe *knights*, when every man who had a knight's-fee was cuſtomarily conſtrained to be a *knight*, were of neceſſity to be *milites gladio cincti*, for ſo the writ runs to this day; but now cuſtom admits eſquires to be choſen to this office.

It is required by 23 Hen. VI. c. 15. that all *knights* of the ſhire ſhall be actual *knights*, or ſuch notable eſquires and gentlemen as have eſtates ſufficient to be *knights*; and by no means of the degree of yeomen: and more preciſely by 9 Ann. c. 5. that every *knight* of the ſhire ſhall have a clear eſtate of freehold or copyhold to the value of 600*l. per annum*, except the eldeſt ſons of peers and of perſons qualified to be *knights* of ſhires. For other qualifications, ſee PARLIAMENT.

The expences of *knights* of the ſhire, are to be defrayed by the county, during their ſitting in parliament, at the rate of four ſhillings a day. This rate of wages was eſtabliſhed in the reign of Edw. III. See alſo 35 Hen. VIII. c. 11. It is hardly neceſſary to add, that theſe are never now required.

KNIGHTS *Croſs*, in *Botany*. See CAMPION.

KNIGHTS, in a *Ship*, two thick, ſhort pieces of timber, uſually carved in the figure of ſome head, having in each four ſhivers, three for the halliards, and one for the top-ropes to run in. One of them ſtands abaft the main-maſt, and for that reaſon is called the *main-knight*. The other ſtands abaft the fore-maſt, on the ſecond deck, and is called the *fore-knight*.

KNIGHTS *fee*, an ancient law-term, ſignifying ſo much land of inheritance as was eſteemed ſufficient to maintain a knight with ſuitable retinue; which, in Henry the Third's days, was reckoned at 15*l. per ann.* And by a ſtat. 1 Edw. II. ſuch as had 20*l. per ann.* in fee, or for life, might be compelled to be knights. But this ſtatute is repealed 17 Car. I. Sir T. Smith rates a *knight's fee* at 40*l.* yearly. According to Coke, a *knight's fee* contained twelve carucates, or plough-lands. Stow ſays, that there were found in England, at the time of the Conqueror, 60,215 *knight's fees*; according to others there were 60,215; whereof the religious houſes, before their ſuppreſſion, were poſſeſſed of 28,015. See FEE.

KNIGHTS *ſervice, ſo whom militare*, a tenure whereby ſeveral lands in this nation were anciently held of the king; which drew after it homage, ſervice in war, eſcuage, wardſhip, marriage, &c. but taken away by the ſtatute 12 Car. II. c. 24.

KNIGHTEN-*gild*, in our *Old Writers*, a *gild* or company in London, conſiſting of nineteen knights, which king Edgar founded, giving them a portion of void ground lying within the walls of the city, now called Portſoken-ward.

KNITTLE, in *Sea-Language*, a ſmall line, which is either plaited or twiſted, and uſed for various purpoſes at ſea; as to faſten the ſervice in the cable, to reef the ſails by the bottom, and to hang the hammocs between decks, &c.

KNOCKING *Mills*. See STAMPING.

KNOLL, a term uſed in many parts of the kingdom, for the top of a ſmall hill, or for the hill itſelf.

KNOTS, in *Gardening*, a term uſed to expreſs the rudiments of the firſt branches of plants, as they grow up from the ſeed. Thus in the melon, the two firſt leaves or ſeed-leaves, are called the ears, and the branches that grow from them are called according to the order of their growth, the firſt, ſecond and third *knots*. Mr. Quintiny's famous method of raiſing the beſt melons, depended principally on the cutting off every third *knot* of the plant as they grew up. Philoſ. Tranſ. N° 45.

In trees, the *knot* denotes that part from whence it ſhoots out branches, roots, or even fruit.

The wood is harder and cloſer in the *knots* than in any other part, but it is alſo more ſubject to ſplit there.

The uſe of the *knots* of plants is to ſtrengthen the ſtem: they ſerve alſo as ſtrainers to filtrate, purify, and refine, the juice raiſed up for the nouriſhment of the plant.

KNOT, on *board a Ship*, is a large knob formed on the extremity of a rope by untwiſting the ends thereof and interweaving them regularly amongſt each other. Of this there are ſeveral ſorts; the chief of which are, the *ſnake-knot*, which is ſo made with the lays of a rope, that it cannot ſlip, and ſerves for ſheats, tacks, and ſloppers. The *bow-line-knot* is ſo firmly made, and faſtened to the crengles of ſails, that they muſt break, or the ſails ſplit, before it will ſlip; the *ſtop-ſhank-knot*, which ſerves to ſhorten a rope without cutting it, which may be preſently looſened; the diamond *knot*, the roſe *knot*, &c. The *knots* are generally uſed to faſten one rope to another, by means of a ſmall cord attached to the neck of the *knot*, called the lanyard, which is firmly tied about both ropes. They are alſo deſigned to prevent the end of a rope from ſliding through an eye, which the *knot* is intended to confine in a particular ſituation.

KNOT-*berries*. See RASPBERRIES.

KNOT-*graſs*, *polygonum*, in *Botany*, the name of a genus of plants, of the *octandria trigynia* claſs, the characters of which are theſe: the flower is of the aperalous kind, being compoſed only of a number of ſtamina ariſing from a tunnel-ſhaped cup, divided into many ſegments at the edge. The piſtil finally becomes an angular ſeed, which is covered by a capſule that was originally the cup of the flower; to this it may be added, that the flowers grow in the axe of the leaves, and that the roots are fibrous.

The ſpecies of *knot-graſs* enumerated by Linnæus, are twenty-ſeven.

The ancients as well as moderns have deſcribed the common kinds of *knot-graſs* under the name of *polygonum*; but as they have alſo given the ſame appellation to another plant, much error has ariſen by miſtaking theſe ſynonyms;

Pliny began the miſtake, and others have ſince in great numbers fallen into it, thinking Pliny's example to be a ſufficient excuſe.

The common great *knot-graſs* is eſteemed a very powerful aſtringent. It is generally uſed in infuſion, and is ſaid to have great virtue in ſtopping hæmorrhages of all kinds.

KNOT-GRASS, *mountain*. See WHITLOW-*Graſs*.

KNOT's of the log-line, at ſea, are the diviſions of it. See LOG.

KNOT, in *Medicine*, a protuberance in the joints of old gouty people: conſiſting of a thick, viſcous, crude, indigeſted pituita, accompanied with a bilious humour, hot and acrimonious; the groſſeſt and moſt terreſtrial part whereof clogs and is converted into a ſtony ſubſtance like chalk. *Knots* appear to be generated like ſtones in the bladder.

Phyſicians ſometimes alſo call them nodes and tophi. See TOPHUS and NODE.

KNOT is alſo uſed for the intrigue of a romance, or dramatic piece; being that part where the perſons are the moſt embarraſſed, by a conjuncture of affairs, whoſe end it is not eaſy to foreſee.

Ariſtotle, under this term, includes all the inciſents of a tragedy, from its beginning to the place where it begins to unravel. The *knot* holds as long as the mind is kept ſuſpended about the event. The *knot* ought always to laſt to the middle of the fifth act, otherwiſe the reſt of the piece languiſhes.

KNOT, *Order of the*, was the name of a military order in the kingdom of Naples, inſtituted in 1352, by queen Jane I. on occaſion of the peace eſtabliſhed between her and the king of Hungary, by means of her marriage with Louis prince of Tarentum.

The order conſiſted of ſixty knights: Clement VI. approved this order, and gave it the rule of St. Baſil: it choſe St. Nicholas for its protector; but it dwindled away after the death of its founderſs.

KNOT, in *Ornithology*, the name of an Engliſh bird of the ſnipe-kind, not known among authors by any particular Latin name, unleſs it be the *calidrys nigra*, or black calidrys of Bellonius, which is doubtful from his deſcription; and ſaid to have obtained its Engliſh name from Canute, one of the Daniſh kings of this iſland, who was particularly fond of it; it is the *tringa Canutus* of Linnæus. It is ſeldom of more than two ounces and a half in weight; its head and back are of a greyiſh brown; its rump is variegated with black and grey; its breaſt and belly are white, and its ſides brownith; in ſome, but not in all the birds of this ſpecies, there is on each ſide of the head a white ſtreak, running from the angles of the beak to the eyes; the long feathers of the wings are black and white; and the tail, which is two fingers breadth and a half in length, has its feathers tipped with white at the ends; its beak is a finger's breadth and a half long, and is black, but it is ſtrouger than any other of the ſnipe kind; its eyes are large, and its legs are green. They appear in Lincolnſhire and Yorkſhireiu the beginning of winter, always keeping about the ſea-ſhores. Their ſeaſon is from the beginning of Auguſt to that of November; and they diſappear with the firſt froſts.

KNOUT is the name of a puniſhment inflicted in Ruſſia, with a kind of whip called *knout*, and made of a long ſtrap of leather prepared for this purpoſe. With this whip the executioners dexterouſly carry off a ſlip of ſkin from the neck to the bottom of the back laid bare to the waiſt, and repeating their blows, in a little while rend away all the ſkin off the back in parallel ſtrips. In the common *knout*, the criminal receives the laſhes ſuſpended on the back of one of the executioners: but in the great *knout*, which is generally uſed on the ſame occaſions as racking on the wheel in France, the criminal is raiſed into the air by means of a pully fixed to the gallows, and a cord faſtened to the two wriſts tied together; a piece of wood is placed between his two legs alſo tied together; and another of a crucial form under his breaſt. Sometimes his hands are tied behind over his back, and when he is pulled up in this poſition, his ſhoulders are diſlocated. The executioners can make this puniſhment more or leſs cruel; and, it is ſaid, are ſo dextrous, that when a criminal is condemned to die, they can make him expire at pleaſure, either by one or ſeveral laſhes.

KNOWING, *principles and rules of*. See PRINCIPLE, and RULE.

KNOWLEDGE, according to Mr. Locke, conſiſts in the perception of the connexion and agreement, or diſagreement and repugnancy, of our ideas. See IDEA.

In which ſenſe, *knowledge* ſtands oppoſed to ignorance.

To *know that white is not black*, is only to perceive that theſe two ideas do not agree. So, in *knowing* that the three angles of a triangle are equal to two right ones; what do we more than perceive, that equality to two right ones neceſſarily agrees to, and is inſeparable from, the three angles of a triangle?

KNOWLEDGE, *kinds of*. For what relates to the agreement or diſagreement of ideas, we may reduce the whole doctrine, and conſequently the whole ſtock of our *knowledge*, to four heads, viz. *identity* or *diverſity*, *relation*, *co-exiſtence*, and *real exiſtence*.

As to the identity or diverſity of our ideas, we may obſerve, that it is the firſt act of the mind to perceive its own ideas; and, ſo far as it perceives them, to *know* what each is, and thereby to perceive their difference; that is, the one not to be the other: by this the mind clearly perceives each idea to agree with itſelf, and to be what it is: and all diſtinct ideas to diſagree. This it does without any pains, or deduction, by its natural power of perception, and diſtinction: and, for doing this, men of art have eſtabliſhed certain general rules or principles; as that, what is, is: and that it is impoſſible for the ſame thing to be, and not to be. But no maxim can make a *man know* clearer, that round is not ſquare, than the bare perception of the two ideas, which the mind, at firſt ſight, perceives to diſagree.

The next kind of agreement, or diſagreement, the mind perceives, in any of its ideas, may be called *relative*, and is nothing but the perception of the relation between any two ideas, of what kind ſoever; that is, their agreement or diſagreement, one with another, in the ſeveral ways, or reſpects, the mind takes of comparing them.

The third ſort of agreement, or diſagreement, to be found in our ideas, is co-exiſtence, or non-co-exiſtence, in the ſame ſubject; and this belongs particularly to ſubſtances. Thus when we pronounce concerning gold, that it is fixed, it amounts to no more but this, that fixedneſs, or a power to remain in the fire unconſumed, is an idea which always accompanies that particular ſort of yellowneſs, weight, fuſibility, &c. which make our complex idea ſignified by the word *gold*.

The fourth ſort is that of actual and real exiſtence, agreeing to any idea.

Within theſe four ſorts of agreement, or diſagreement, ſeems contained all the *knowledge* we have, indeed all we are capable of; for all that we *know*, or can aſſirm, concerning any idea, is, that it is, or is not, the ſame with ſome other; as, that blue is not yellow: that it does, or does not, coexiſt with another in the ſame ſubject; as, that iron is ſuſceptible of magnetical impreſſions: that it hath that or this relation to ſome other idea; as, that two triangles upon equal baſes, between the ſame parallels, are equal: or, that it has a real exiſtence without the mind; as, that God is.

The mind becomes poſſeſſed of truth in ſeveral manners, which conſtitute ſo many different ſpecies of *knowledge*. Thus, when the mind has a perfect view of the agreement or diſagreement of any of its ideas, or of the relation they have one with another, it is called *actual knowledge*.

Secondly, a man is ſaid to *know* any propoſition, when, having once evidently perceived the agreement or diſagreement of the ideas wherein it conſiſts, and ſo lodged it in his memory, that whenever it comes to be reflected on again, the mind aſſents to it without doubt or heſitation, and is certain of the truth of it: this may be called *habitual knowledge*. And thus a man may be ſaid to *know* all thoſe truths which are lodged in his memory, by a foregoing, clear, and full perception.

Of habitual *knowledge*, there are two ſorts: the one conſiſts of ſuch truths, laid up in the memory, as, whenever they occur to the mind, it actually perceives the relation that is between their ideas; and this is in all thoſe truths where the ideas themſelves, by an immediate view, diſcover their agreement or diſagreement one with another. The other is of ſuch truths, whereof the mind having been convinced, it remins the memory of the conviction, without the proofs. Thus a man that remembers certainly, that he once perceived the demonſtration, that the three angles of a triangle are equal to two right ones, *knows* it to be true, when that demonſtration is gone out of his mind, and cannot poſſibly be recollected: but he *knows* it in a different way from what he did before; namely, not by the intervention of thoſe intermediate ideas; whereby the agreement, or diſagreement, of thoſe in the propoſition was at firſt perceived; but by remembering, that is, *knowing*, that he was once certain of the truth of this propoſition, that the three angles of a triangle are equal to two right ones,—the immutability of the ſame relation between the ſame immutable things, is now the idea that ſhews him, that if the three angles of a triangle were once equal to two right ones, they will always be ſo. And hence he comes to be certain, that what was once true, is always true; what ideas once agreed, will always agree; and conſequently, what he once *knew* to be true, he will always *know* to be true, as long as he can remember that he once knew it.

KNOWLEDGE alſo may be uſefully diſtinguiſhed into three kinds; hiſtorical, philoſophical, and mathematical.

KNOWLEDGE, *hiſtorical*, is merely the knowledge of facts, or of what is or happens in the material world, or within our own minds. Thus, that the ſun riſes and ſets, that trees bud in the ſpring, that we remember, will, &c. are inſtances of *hiſtorical knowledge*.

KNOWLEDGE, *philoſophical*, is the *knowledge* of the reaſons of things, or of what is or happens. Thus he has a *philoſophical knowledge* of the motion of rivers, who can explain how it ariſes from the declivity of the bottom, and from the preſſure which the lower part of the water ſuſtains from the upper. So likewiſe the ſhewing how, and by what reaſon, deſire or appetite ariſes from the perception or imagination of its object, would be *philoſophical knowledge*.

KNOWLEDGE, *mathematical*, is the *knowledge* of the quantity of things, that is, of their proportions or ratios to ſome given meaſure. Thus he who knows the proportion of the meridian heat of the ſun at the ſummer ſolſtice to its meridian heat at the winter ſolſtice, might ſo far be ſaid to have a *mathematical knowledge* of the ſun's heat. So likewiſe he has a *mathematical knowledge* of the motion of a planet in its orbit, who can diſtinctly ſhew how, from the quantity of the impreſſed and centripetal force, the velocity of the planet is produced; and how, from the action of this double force, the elliptical figure of the orbit ariſes.

Theſe three kinds of *knowledge*, differ evidently, it being one thing to know that a thing is; another, the reaſon why it is; and a third, to know, its quantity or meaſure.

It is alſo evident, that hiſtorical *knowledge*, though extenſively uſeful, and the foundation of the reſt, is the loweſt degree of human *knowledge*. Thoſe who aim at the greateſt certainty ought to join *mathematical* with *philoſophical knowledge*. Nothing can more evidently ſhew that an effect ariſes from a certain cauſe, than the *knowledge* that the quantity of the effect is proportional to the force of the cauſe. Beſides, there are many things in nature, the reaſons of which depending on certain figures or quantities, are not aſſignable but from mathematical principles.

KNOWLEDGE, *degrees of*. As to the different degrees, or clearneſs of our *knowledge*, it ſeems to lie in the different way which the mind has of perceiving the agreement or diſagreement of any of its ideas. When the mind perceives this agreement or diſagreement of two ideas immediately by themſelves, without the intervention of any other, we may call it *intuitive knowledge*; in which caſe the mind perceives the truth, as the eye doth light, only by being directed towards it. Thus the mind perceives that white is not black; that three are more than two, and equal to one and two. This part of *knowledge* is irreſiſtible; and, like the bright ſun-ſhine, forces itſelf immediately to be perceived, as ſoon as ever the mind turns its view that way. It is on this intuition that all the certainty and evidence of our other *knowledge* depends; which certainly every one finds to be ſo great, that he cannot imagine, and therefore cannot require a greater.

The next degree of *knowledge* is, where the mind perceives not this agreement, or diſagreement, immediately, or by the juxtapoſition, as it were, of the ideas; becauſe thoſe ideas, concerning whoſe agreement, or diſagreement, the inquiry is made, cannot, by the mind, be ſo put together, as to ſhew it. In this caſe, the mind is obliged to diſcover the agreement, or diſagreement, which it ſearches for, by the intervention of other ideas: and this is that which we call *reaſoning*.

Thus, if we would *know* the agreement, or diſagreement, in bigneſs, between the three angles of a triangle and two right angles, we cannot do it by an immediate view and compariſon of them, becauſe the three angles of a triangle cannot be brought together at once, and compared with any other one or two angles; and ſo of this the mind has no immediate or intuitive *knowledge*. But we muſt find out ſome other angles, to which the three angles of a triangle have equality; and, finding thoſe equal to two right ones, we come to *know* the equality of theſe three angles to two right ones.

Thoſe intervening ideas, which ſerve to ſhew the agreement of any two others, are called *proofs*; and where the agreement, or diſagreement, is by this means plainly and clearly perceived, it is called *demonſtration*: and a quickneſs in the mind to find thoſe proofs, and to apply them right, is that which is called *ſagacity*.

This *knowledge*, though it be certain, is not ſo clear and evident as intuitive *knowledge*; it requires pains and attention, and ſteady application of mind, to diſcover the agreement, or diſagreement, of the ideas it conſiders; and there muſt be a progreſſion by ſteps and degrees, before the mind can, in this way, arrive at any certainty.

Before demonſtration, there was a doubt, which, in intuitive *knowledge*, cannot happen to the mind, that has its faculty of perception left in a degree capable of diſtinct ideas, no more than it can be a doubt to the eye (that can diſtinctly ſee white and black), whether this ink and paper be all of a colour. Now, in every ſtep that reaſon makes in demonſtrative *knowledge*, there is an intuitive *knowledge* of that agreement, or diſagreement, it ſeeks with the next intermediate idea, which it uſes as a proof: for, if it were not ſo, that yet would need a proof, ſince, without the perception of ſuch agreement, or diſagreement, there is no *knowledge* produced.

By which it is evident, that every ſtep in reaſoning, that produces *knowledge*, has intuitive certainty; which, when the mind perceives, there is no more required, but to remember it, to make the agreement, or diſagreement, of the ideas, concerning which we inquire, viſible and certain. This intuitive perception of the agreement, or diſagreement, of the intermediate ideas in each ſtep and progreſſion of the demonſtration, muſt alſo be exactly carried in the mind; and a man muſt be ſure, that no part is left out, which, becauſe in long deductions the memory cannot eaſily retain, this *knowledge* becomes more imperfect than intuitive, and men often embrace falſhoods for demonſtrations.

It has been generally taken for granted, that mathematics alone are capable of demonſtrative certainty: but to have ſuch an agreement, or diſagreement, as may be intuitively perceived, being, as we imagine, not the privilege of the ideas of number, extenſion, and figure alone, it may, poſſibly, be the want of due method and application in us, and not of ſufficient evidence in things, that demonſtration has been thought to have ſo little to do in other parts of *knowledge*. For, in whatever ideas the mind can perceive the agreement, or diſagreement, immediately, there it is capable of intuitive *knowledge*; and, where it can perceive the agreement, or diſagreement, of any two ideas, by the intuitive perception of the agreement, or diſagreement, they have with any intermediate ideas, there the mind is capable of demonſtration, which is not limited to the ideas of figure, number, extenſion, or their modes.

The reaſon why it has been generally ſuppoſed to belong to theſe only, is, becauſe, in comparing their equality or excels, the modes of numbers have every the leaſt difference very clear and perceivable: and, in extenſion, though every the leaſt excels is not ſo perceptible, yet the mind has found out ways to diſcover the juſt equality of two angles, extenſions, or figures; and both numbers and figures can be ſet down by viſible and laſting marks. But, in other ſimple ideas, whoſe modes and differences are made and counted by degrees, and not quantity, we have not ſo nice and accurate a diſtinction of their differences, as to perceive or find ways to meaſure their juſt equality, or their leaſt differences. For, theſe other ſimple ideas being appearances, or ſenſations produced in us, by the ſize, figure, motion, &c. of minute corpuſcles, finely inſenſible, their different degrees alſo depend on the variation of ſome or all of thoſe cauſes; which, ſince it cannot be obſerved by us in particles of matter, whereof each is too ſubtile to be perceived, it is impoſſible for us to have any exact meaſures of the different degrees of theſe ſimple ideas.

Thus, not knowing what number of particles, nor what motion of them, is fit to produce any preciſe degree of whiteneſs, becauſe we have no certain ſtandard to meaſure them by, nor means to diſtinguiſh every the leaſt difference; the only help we have, is from our ſenſes, which, in this point, fail us. But where the difference is ſo great as to produce in the mind ideas clearly diſtinct, theſe ideas, as we ſee in colours of different kinds, blue and red for inſtance, are as capable of demonſtration, as ideas of number and extenſion. And what is here ſaid of colours, holds true in all ſecondary qualities.

Theſe two then, *intuition* and *demonſtration*, are the degrees of our *knowledge*; and whatever comes ſhort of one of theſe, is only *faith*, or *opinion*, but not *knowledge*, as leaſt, in all general truths.

There is, indeed, another perception of the mind, employed about the particular exiſtence of finite beings without us, which going beyond probability, but not reaching to either of the foregoing degrees of certainty, paſſes under the name of *knowledge*.

Nothing can be more certain, than that the idea we receive from an external object is in our minds: this is intuitive *knowledge*; but whether we can thence certainly infer the exiſtence of any thing without us, correſponding to that idea, is that, whereof ſome men think there may be a queſtion made; becauſe men may have ſuch an idea in their minds, when no ſuch thing exiſts, nor any ſuch object affects their ſenſes.

But it is evident, that we are invincibly conſcious to ourſelves

ſelves of a different perception, when we look on the ſun in the day, and when we think on it by night; when we actually taſte wormwood, or ſmell a roſe, or only think on that ſavour or odour; ſo that we may add, to the two former ſorts of *knowledge*, this alſo of the exiſtence of particular external objects, by that perception and conſciouſneſs we have of the actual entrance of ideas from them; and allow theſe three degrees of *knowledge*, viz. *intuitive*, *demonſtrative*, and *ſenſitive*.

But, ſince our *knowledge* is founded on, and employed about, our ideas only, will it follow thence, that it muſt be conformable to our ideas, and that where our ideas are clear and diſtinct, obſcure and confuſed, there our *knowledge* will be ſo too? We anſwer, No; for our *knowledge* conſiſting in the perception of the agreement, or diſagreement, of any two ideas; its clearneſs or obſcurity conſiſts in the clearneſs and obſcurity of that perception, and not in the clearneſs or obſcurity of the ideas themſelves. A man (for inſtance), who has a clear idea of the angles of a triangle, and of equality to two right ones, may yet have but an obſcure perception of their agreement, and ſo have but a very obſcure *knowledge* of it: but obſcure and confuſed ideas can never produce any clear or diſtinct *knowledge*; becauſe, as far as any ideas are obſcure or confuſed, ſo far the mind can never perceive clearly, whether they agree or diſagree; or, to expreſs the ſame thing in other words, he that has not determined ideas to the words he uſes, cannot make propoſitions of them, of whoſe truth he can be certain.

From all this it follows; 1. That we can have no *knowledge* farther than we have ideas.

2. That we have no *knowledge* farther than we can have perception of the agreement, or diſagreement, of our ideas, either by intuition, demonſtration, or ſenſation.

3. We cannot have an intuitive *knowledge*, that ſhall extend itſelf to all our ideas, and all that we would *know* about them; becauſe we cannot examine and perceive all the relation they have one to another by juxtapoſition, or in immediate compariſon one with another. Thus, we cannot intuitively perceive the equality of two extenſions, the difference of whoſe figures makes their parts incapable of an exact immediate application.

4. Our rational *knowledge* cannot reach to the whole extent of our ideas; becauſe, between two different ideas which we would examine, we cannot always find ſuch proofs, whereby we can connect one to another with an intuitive *knowledge* in all the parts of the deduction.

5. Senſitive *knowledge*, reaching no farther than the exiſtence of things actually preſent to our ſenſes, is yet much narrower than either of the former.

6. From all which it is evident, that the extent of our *knowledge* comes not only ſhort of the reality of things, but even of the extent of our own ideas. We have the idea of a ſquare, a circle, and equality; and yet perhaps, ſhall never be able to find a circle equal to a ſquare. See CIRCLE.

KNOWLEDGE, *extent and limits of*. The affirmations or negations we make concerning the ideas we have, being reduced to the four ſorts above mentioned, viz. identity, coexiſtence, relation, and real exiſtence, let us inquire how far our *knowledge* extends in each of theſe. 1. As to identity and diverſity, our intuitive *knowledge* is as far extended, as our ideas themſelves; and there can be no idea in the mind, which it does not preſently, by an intuitive *knowledge*, perceive to be what it is, and to be different from any other.

2. As to the agreement, or diſagreement, of our ideas of co-exiſtence, our *knowledge* herein is very defective, though it is in this that the greateſt and moſt material part of our *knowledge*, concerning ſubſtances, conſiſts: for our ideas of ſubſtances being nothing but certain collections of ſimple ideas co-exiſting in one ſubject (our idea of flame, for inſtance, is a body hot, luminous, and moving upwards); when we would know any thing farther, concerning this, or any other ſort of ſubſtance, what do we but enquire what other qualities, or powers, theſe ſubſtances have, or have not? which is nothing elſe but to *know* what other ſimple ideas do, or do not exiſt with thoſe which make up ſuch complex ideas. The reaſon of this is, that the ſimple ideas, which make up our complex ideas of ſubſtances, have no viſible neceſſary connection, or inconſiſtence, with other ſimple ideas, whoſe co-exiſtence with them we would inform ourſelves about. Theſe ideas being likewiſe, for the moſt part, ſecondary qualities, which depend upon the primary qualities of their minute or inſenſible parts, or on ſomething yet more remote than theſe from our comprehenſion, it is impoſſible we ſhould *know* which have a neceſſary union, or inconſiſtence, one with another; ſince we *know* not the root from whence they ſpring, or the ſize, figure, and texture of parts on which they depend, and from which they reſult. Beſides this there is no diſcoverable connection between any ſecondary quality, and thoſe primary qualities that it depends on. We are ſo far from *knowing* what figure, ſize, or motion, produces (for inſtance) a yellow colour, or ſweet taſte, or ſharp ſound, that we can by no means conceive how any ſize, figure, or motion, can poſſibly produce in us the idea of any colour, taſte, or ſound, whatſoever; there being no conceivable connection between the one and the other.

Our *knowledge*, therefore, of co-exiſtence reaches little farther than experience. Some few, indeed, of the primary qualities have a neceſſary dependence, and viſible connection, one with another: as figure neceſſarily ſuppoſes extenſion; receiving or communicating motion by impulſe ſuppoſes ſolidity; but qualities co-exiſtent in any ſubject, without this dependence and connection, cannot certainly be *known* to co-exiſt, any farther than experience, by our ſenſes, informs us. Thus, though, upon trial, we find gold yellow, weighty, malleable, fuſible, and fixed; yet, becauſe none of theſe have any evident dependence, or neceſſary connection, with the other, we cannot certainly *know*, that, where any four of theſe are, the fifth will be there alſo, how highly probable ſoever it may be. But the higheſt degree of probability amounts not to certainty, without which there can be no true *knowledge*; for this co-exiſtence can be no farther *known* than it is perceived; and it cannot be perceived, but either, in particular ſubjects, by the obſervation of our ſenſes, or, in general, by the neceſſary connection of the ideas themſelves.

As to incompatibility, or repugnancy to co-exiſtence, we *know*, that no ſubject can have of each ſort of primary qualities, more than one particular at once, as one extenſion, or one figure; and ſo of ſenſible ideas peculiar to each ſenſe: for whatever, of each kind, is preſent in any ſubject, excludes all other of that ſort: for inſtance, one ſubject cannot have two ſmells, or two colours, at the ſame time.

As to powers of ſubſtances, which make a great part of our inquiries about them, our *knowledge* reaches little farther than experience; becauſe they conſiſt in a texture and motion of parts, which we cannot by any means come to diſcover; and I doubt, whether, with thoſe faculties we have, we ſhall ever be able to carry our general *knowledge* much farther in this part. Experience is that, which, in this part, we muſt depend on: and it were to be wiſhed, that it were more improved. We find the advantages ſome men's generous pains have this way brought to the ſtock of natural *knowledge*; and if others, eſpecially the philoſophers by fire, had been ſo wary in their obſervations, and ſincere in their reports, as thoſe who call themſelves *philoſophers* ought to have been, our acquaintance with the bodies here about us, and our inſight into their powers and operations, might have been yet much greater.

As to the third ſort, the agreement, or diſagreement, of our ideas in any other relation; this is the largeſt field of *knowledge*, and it is hard to determine how far it may extend; this part depending on our ſagacity in finding intermediate ideas, that may ſhew the habitudes and relations of ideas, it is a hard matter to tell when we are at an end of ſuch diſcoveries. They, who are ignorant of algebra, cannot imagine the wonders of this kind that are to be done by it: and what farther improvements and helps, advantageous to other parts of *knowledge*, the ſagacious mind of man may yet find out, it is not eaſy to determine.

Thus, at leaſt, we may believe, that the ideas of quantity are not the only ones capable of demonſtration and *knowledge*; and that other, and, perhaps, more uſeful parts of contemplation, would afford us certainty, if vices, paſſions, and domineering intereſt, did not oppoſe or menace endeavours of this kind.

As to the fourth ſort of *knowledge*, viz. *of the real, actual exiſtence of things*, we have an intuitive *knowledge* of our own exiſtence, a demonſtrative *knowledge* of the exiſtence of God, and a ſenſitive *knowledge* of the objects that preſent themſelves to our ſenſes.

Hitherto we have examined the extent of our *knowledge*, in reſpect of the ſeveral ſorts of beings that are: there is another extent of it, in reſpect of univerſality, which will alſo deſerve to be conſidered; and this in regard our *knowledge* follows the nature of our ideas. If the ideas, whoſe agreement, or diſagreement, we perceive, are abſtract, our *knowledge* is univerſal; for what is *known* of ſuch general ideas, will be true of every particular thing, in which that eſſence, that is, that abſtract idea, is found: and what is once *known* of ſuch ideas, will be perpetually and for ever true; ſo that, as to all general *knowledge*, we muſt ſearch and find it only in our own minds; and it is only the examining our own ideas that furniſhes us with it. Truth belonging to eſſences of things (that is, to abſtract ideas) are eternal, and are to be found out by the contemplation only of theſe eſſences; as the exiſtence of things is to be known only from experience.

KNOWLEDGE, *reality of.* It is evident, that the mind *knows* not things immediately, but by the intervention of the ideas it has of them. Our *knowledge*, therefore, is real only so far as there is a conformity between our ideas, and the reality of things. But how shall we *know* when our ideas agree with things themselves? It is answered, There are two sorts of ideas, that we may be assured agree with things: these are,

1. *Simple ideas*, which, since the mind can by no means make to itself, must be the effect of things operating upon the mind in a natural way, and producing therein those perceptions, which, by the will of our Maker, they are ordained and adapted to. Hence it follows, that simple ideas are not fictions of our fancies, but the natural and regular production of things without us, really operating upon us, which carry with them all the conformity our state requires, which is to represent things under those appearances they are fitted to produce in us. Thus the idea of whiteness, as it is in the mind, exactly answers that power which is in any body to produce it there; and this conformity between our simple ideas, and the existence of things, is sufficient for real *knowledge*.

2. All our *complex ideas*, except only those of substances, being archetypes of the mind's own making, and not referred to the existence of things, as to their originals, cannot want any conformity necessary to real *knowledge*; for that which is not designed to represent any thing but itself, can never be capable of a wrong representation. Here the ideas themselves are considered as archetypes, and things are no otherwise regarded than as conformable to them. Thus the mathematician considers the truth and properties belonging to a rectangle, or circle, only as they are ideas in his own mind, which possibly he never found existing mathematically, that is, precisely, true; yet his *knowledge* is not only certain, but real, because real things are no farther concerned, nor intended to be meant by any such propositions, than as things really agree to those archetypes in the mind.

3. But the *complex ideas*, which we refer to archetypes without us, may differ from them; and so our *knowledge* about them may come short of being real: and such are our ideas of substances. These must be taken from something, that does or has existed, and not be made up of ideas arbitrarily put together, without any real pattern. Herein, therefore, is founded the reality of our *knowledge* concerning substances, that all our complex ideas of them must be such, and such only as are made up of such simple ones as have been discovered to co-exist in nature: and our ideas, being thus true, though not, perhaps, very exact copies, are the subject of real *knowledge* of them. Whatever ideas we have, the agreement we find they have with others will be *knowledge*. If those ideas be abstract, it will be general *knowledge*; but, to make it real concerning substances, the ideas must be taken from the real existence of things. Wherever, therefore, we perceive the agreement, or disagreement, of our ideas, there is certain *knowledge*; and wherever we are sure those ideas agree with the reality of things, there is certain, real *knowledge*.

KNOWLEDGE, *method of improving or enlarging.* It being the received opinion amongst men of letters, that maxims are the foundation of all *knowledge*, and that sciences are each of them built upon certain præcognita, from whence the understanding is to take its rise, and by which it is to conduct itself in its enquiries in the matters belonging to that science; the beaten road of the schools has been to lay down, in the beginning, one or more general propositions, called *principles*, as foundations whereon to build the *knowledge* that was to be had of that subject.

That which gave occasion to this way of proceeding was, the good success it seemed to have in mathematics, which of all the sciences, have the greatest certainty, clearness, and evidence in them. But, if we consider it, we shall find, that the great advancement and certainty of real *knowledge* men arrive to in these sciences, was not owing to the influence of those principles, but to the clear, distinct and complete ideas, their thoughts were employed about, and to the relation of equality and excess, so clear between some of them, that they had an intuitive *knowledge*, and by that a way to discover it in others, and this is without the help of those maxims. For is it not possible for a lad to *know*, that his whole body is bigger than his little finger, but by virtue of this axiom, the whole is bigger than a part; nor be assured of it till he has learned that maxim? Let any one consider which is *known* first and clearest by most people, the particular instance, or the general rule: and which it is that gives life and birth to the other: these general rules are but the comparing our more general and abstract ideas, which ideas are made by the mind, and have names given them, for the easier dispatch in its reasonings: but *knowledge* began in the mind, and was founded on particulars, though afterwards, perhaps, no notice be taken thereof, it being natural for the mind to lay up those general notions, and make the proper use of them, which is to disburden the memory of the cumbersome load of particulars. The way to improve in *knowledge* is, not to swallow principles with an implicit faith, and without examination, which would be apt to mislead men, instead of guiding them into truth; but to get and fix in our minds clear and complete ideas, as far as they are to be had, and to annex to them proper and constant names: and thus, barely by considering our ideas, and comparing them together, observing their agreement or disagreement, their habitudes and relations, we shall get more true and clear *knowledge* by the conduct of this one rule, than by taking up principles, and thereby putting our minds into the disposal of others.

We must therefore, if we will proceed as reason advises us, adapt our methods of inquiry to the nature of the ideas we examine, and the truth we search after. General and certain truths are only founded on the habitudes and relations of abstract ideas; therefore a sagacious, methodical application of our thoughts for the finding out these relations, is the only way to discover all, that can with truth and certainty be put into general propositions. By what steps we are to proceed in these, is to be learned in the schools of the mathematicians, who, from very plain and easy beginnings, by gentle degrees, and a continued chain of reasonings, proceed to the discovery and demonstration of truths, that, at first sight, appeared beyond human capacity. This may reasonably be said, that, if other ideas that are real, as well as nominal essences of their species, were pursued in the way familiar to mathematicians, they would carry our thoughts farther, and with greater evidence and clearness, than possibly we are apt to imagine. This is reason sufficient to advance that conjecture above mentioned; viz. "That "morality is capable of demonstration, as well as mathe-"matics;" for moral ideas being real essences, which have a discoverable connection and agreement one with another, so far as we can find their habitudes and relations, so far we shall be possessed of real and general truths.

In our *knowledge* of substances, we are to proceed after a quite different method; the bare contemplation of their abstract ideas (which are but nominal essences) will carry us but a very little way in the search of truth and certainty. Here experience must teach us what reason cannot; and it is by trying alone, that we can certainly *know* what qualities co-exist with those of our complex idea; for instance, whether that yellow, heavy, fusible body, I call *gold*, be malleable, or no; which experience (however it prove in that particular body we examine) makes us not certain that it is so in all, or any other yellow, heavy, fusible bodies, but that which we have tried; because it is no consequence, one way or other, from our complex idea. The necessity or inconsistence of malleability has no visible connection with the combination of that colour, weight, and fusibility, in any body. What is here said of the nominal essence of gold, supposed to consist of a body of such a determinate colour, weight, and fusibility, will hold true if other qualities be added to it. Our reasonings from those ideas will carry us but a little way in the certain discovery of the other properties in those masses of matter wherein all those are to be found. As far as our experience reaches, we may have certain *knowledge*, and no farther. It is not denied, but that a man, accustomed to rational and regular experiments, shall be able to see farther into the nature of bodies, and their unknown properties, than one that is a stranger to them: but this is but judgment and opinion, not *knowledge* and certainty.

This would make it suspected, that natural philosophy is not capable of being made a science. From experiments, and historical observations, we may draw advantages of ease and health, and thereby increase our stock of conveniences for this life; but, beyond this, it is to be feared, our talents reach not, nor are our faculties able to advance farther. See PHYSICS.

The ways to enlarge our *knowledge*, as far as we are capable, seem to be these two: the first is, to get and settle in our minds, as far as we can, clear, distinct, and constant ideas of those things we would consider and *know*; for it being evident that our *knowledge* cannot exceed our ideas, where they are either imperfect, confused, or obscure, we cannot expect to have certain, perfect, or clear *knowledge*. The other art is, of finding out the intermediate ideas, which may shew us the agreement or repugnancy of other ideas, which cannot be immediately compared.

That these two (and not relying on maxims, and drawing consequences from some general propositions) are the right method of improving our *knowledge* in the ideas

of

of other modes, beſides thoſe of quantity, the conſideration of mathematical *knowledge* will eaſily inform us; where, firſt, we ſhall find, that he, who has not clear and perfect ideas of thoſe angles or figures, of which he deſires to *know* any thing, is utterly thereby incapable of any *knowledge* about them. Suppoſe a man not to have an exact idea of a right angle, ſcalenum, or trapezium, and it is clear, that he will in vain ſeek any demonſtration about them.

And farther, it is evident, that it was not the influence of maxims or principles that led the maſters of this ſcience into thoſe wonderful diſcoveries they have made: let a man of good parts *know* all the maxims of mathematics ever ſo well, and contemplate their extent and conſequences as much as he pleaſes, he will, by their aſſiſtance, ſcarce ever come to *know*, that the ſquare of the hypothenuſe in a right-angled *triangle*, is equal to the ſquares of the two other ſides. This, and other mathematical truths, have been diſcovered by the thoughts otherwiſe applied. The mind had other objects, other views before it, far different from thoſe maxims, which men, well enough acquainted with thoſe received axioms, but ignorant of their method who firſt made thoſe demonſtrations, can never ſufficiently admire.

Our *knowledge*, as in other things, ſo in this alſo, has ſo great a conformity with our ſight, that it is neither wholly neceſſary, nor wholly voluntary. Men, who have ſenſes, cannot chooſe but receive ſome ideas by them; and, if they have memory, they cannot but retain ſome of them; and if they have any diſtinguiſhing faculty, cannot but perceive the agreement or diſagreement of ſome of them one with another. As he that has eyes, if he will open them by day, cannot but ſee ſome objects, and perceive a difference in them; yet he may chooſe whether he will turn his eyes towards an object, cuſtomarily ſurvey it, and obſerve accurately all that is viſible in it. But what he doth ſee he cannot ſee otherwiſe than he doth; it depends not on his will to ſee that black, which appears yellow. Juſt thus it is with our underſtanding: all that is voluntary in our *knowledge*, is the employing or with-holding any of our faculties from this or that ſort of objects, and a more or leſs accurate ſurvey of them; but, they being employed, our will hath no power to determine the *knowledge* of the mind one way or another; that is done only by the objects themſelves, as far as they are clearly diſcovered. Thus, he that has got the ideas of numbers, and has taken the pains to compare one, two, or three, to ſix, cannot chooſe but *know* they are equal. He alſo, that hath the idea of an intelligent, but weak and frail being, made by, and depending on, another, who is eternal, omnipotent, and perfectly wiſe and good, will as certainly know, that man is to honour, fear, and obey God, as that the ſun ſhines when he ſees it. But yet, he thoſe truths ever ſo certain, ever ſo clear, he may be ignorant of either or both of them, who will not take the pains to employ his faculties as he ſhould, to inform himſelf about them.

KNOXIA, in *Botany*, a genus of the *tetrandria monogynia* claſs; the characters of which are, that the flower conſiſts of a ſingle petal, and is funnel-ſhaped; and its ſeeds are two, and ſulcated.

KODDA-*pail*, in *Botany*, a name given by Plumier, and in the Hortus Malabaricus, to a genus of plants, called by Linnæus PISTIA.

KOEMPFERIA, in *Botany*. *See* GALANGAL.

KOENIGIA, in *Botany*, a genus of the *triandria trigynia* claſs; the characters of which are, that the calyx is formed of three leaves; that it has no corolla; and the ſeed is ſingle, ovated, and naked.

KOHLMULEN, in *Ichthyography*, a name given by ſome to the *oſſilus flaveſcens*, or yellow cod, called by others *blank* and *gelbe*.

KOKOB, in *Zoology*, the name of a ſpecies of ſerpent, found in the Weſt Indies, and very fatal by its bite. It is ſmaller than our viper, and of a brown colour, variegated with green and red ſpots.

KOLERUS, a name given by Paracelſus to an old dry ulcer.

KOLLOW. *See* KILLOW.

KOLTO, a name given by ſome writers to the PLICA *Polonica*.

KOMMANICK, in *Ornithology*, the German name for the large-creſted lark, common in many parts of Germany, but not known in England. It is larger than our common lark, and has a much larger and longer beak; its back is of a greyer colour, and leſs ſpotted than in the common lark; and its rump is ſcarce ſpotted at all; its creſt is very beautiful, and is compoſed of eight, ten, or twelve, feathers, much darker coloured than the reſt, and the bird can not only raiſe and depreſs, but can ſpread and contract them at pleaſure; it very ſeldom is ſeen high in the air, and never makes any long ſtay there, but is moſt frequently ſeen about the banks of rivers.

KONNARUS, a name given by Agathocles in Athenæus to a plant of Arabia, which the deſcription ſhews to be the ſame with the *ſadus* of the later Arabians, the fruit of which is called *nabac* or *nabech*.

This tree is the *lotus* of Dioſcorides, and the *acanthus* of Virgil, whoſe berries he mentions. The fruit of this tree is like a cherry, but ſmaller, and is ground to powder by the Africans when dried. It is very well known to all who are acquainted with the writings of the old phyſicians, that the berries of the *lotus* or *nabac* were ground down, by the Egyptians and other nations where they grew, to a fine powder for medicinal uſes. They were aſtringents, and uſed both externally in poultices and fomentations, and internally in decoctions and other forms where aſtringents were required.

KORACHORYNCHUS *Indicus*, in *Ichthyology*, the name of a ſea-fiſh of the Eaſt Indies, called by the Dutch the *roevenbeck*. It has its name from its noſe reſembling the beak of a raven or crow, and is about ſeven inches long; its back and tail are red, and its belly yellow; it has alſo on each ſide two pale yellow longitudinal lines, running from the gills to the tail. It is a wholeſome and well-taſted fiſh. Ray.

KORAN. *See* ALCORAN.

KOS, in the *Jewiſh Antiquities*, a meaſure which held the quantity of four cubic inches, and ſomething over. This was the cup of bleſſing, out of which they drank when they gave thanks after ſolemn meals, as on the day of the paſſover.

KOUANIN, in the *Chineſe Language*, the name of a tutelary deity of women. The Chineſe make great numbers of the figures of this deity in white porcelain, and ſend them to all parts of the world, as well as keep them in their own houſes. The figure repreſents a woman with a child in her arms. The women, who have no children, pay a ſort of adoration to theſe images, and ſuppoſe the deity they repreſent to be of power to make them fruitful. It has been ſuppoſed, by many Europeans, that theſe images were meant to repreſent the Virgin Mary, with our Saviour in her arms; but this is an idle opinion; the Chineſe have been fond of this figure in all times that we have an account of. The ſtatue always repreſents an handſome woman, very modeſtly attired.

KRAKEN, in *Zoology*, a moſt amazing large ſea animal, ſeemingly of a crab-like form; the credit of whoſe exiſtence reſts upon the evidence produced by biſhop Pontoppidon, in his Natural Hiſtory of Norway, publiſhed ſome few years ſince; and though the reality of it cannot be denied, the relation will be thought to require good authentication.

As a full grown *kraken* has never been ſeen in all its parts and dimenſions, an accurate ſurvey of which muſt employ ſome time, and not a little motion; it is impoſſible to give a complete deſcription of one. Nevertheleſs, we ſhall ſubmit the probability of its exiſtence on the beſt information our author could collect, which ſeems to have fixed his own belief of it; though, at the ſame time, he acknowledges the account is very defective, and ſuppoſes a farther information concerning the creature may be reſerved for poſterity.

Our fiſhermen, ſays the author, unanimouſly and invariably affirm, that when they are ſeveral miles from the land, particularly in the hot ſummer days, and by their diſtance, and the bearings of ſome points of land, expect from eighty to a hundred fathoms depth, and do not find but from twenty to thirty; and more eſpecially if they find a more than uſual plenty of cod and ling, they judge that the *kraken* is at the bottom; but if they find by their lines, that the water in the ſame place ſtill ſhallows on them, they know he is riſing to the ſurface, and row off with the greateſt expedition, till they come into the uſual ſoundings of the place; when, lying on their oars, in a few minutes the monſter emerges, and ſhews himſelf ſufficiently, though his whole body does not appear. Its back, or upper part, which ſeems an Engliſh mile and a half in circumference (ſome have affirmed more), looks at firſt like a number of ſmall iſlands, ſurrounded with ſomething that floats like ſea-weeds; at laſt, ſeveral bright points or horns appear, which grow thicker the higher they emerge, and ſometimes ſtand up as high and large as the maſts of middle ſized veſſels. In a ſhort time it ſlowly ſinks, which is thought as dangerous as its riſing; as it cauſes ſuch a ſwell and whirlpool, as draws every thing down with it, like that of Maleſtrom. The biſhop juſtly regrets the omiſſion of, probably, the only opportunity that ever has, or may be preſented, of ſurveying it alive, or ſeeing it entire when dead. This, he informs us, once did occur, on the credit of the reverend Mr. Frois, miniſter at Nordland, and vicar of the college for promoting Chriſtian knowledge; who informed him, that in 1680, a *kraken* (perhaps a young and careleſs one, as they generally keep ſeveral leagues from land) came into the

the waters that run between the rocks and cliffs near Alftahoug; where, in turning about, some of its long horns caught hold of some adjoining trees, which it might eaſily have torn up, but that it was alſo entangled in ſome cliffs of the rock, whence it could not extricate itſelf, but putrefied on the ſpot. Our author has heard of no perſon deſtroyed by this monſter, but relates a report of the danger of two fiſhermen, who came upon a part of the water full of the creature's thick ſlimy excrements (which he voids for ſome months, as he feeds for ſome other); they immediately ſtrove to row off, but were not quick enough in turning to ſave the boat from one of the *kraken's* horns, which ſo cruſhed the head of it, that it was with difficulty they ſaved their lives on the wreck, though the weather was perfectly calm; the monſter never appearing at other times. His excrement is ſaid to be attractive of other fiſh, on which he feeds; which expedient was probably neceſſary, on account of his ſlow unwieldy motion, to his ſubſiſtence; as this ſlow motion again may be neceſſary to the ſecurity of ſhips of the greateſt force and burthen, who muſt be overwhelmed on encountering ſuch an immenſe animal, if his velocity was equal to his weight: the Norwegians ſuppoſing, that if his arms on which he moves, and with which he takes his food, were to lay hold of the largeſt man of war, they would pull it down to the bottom.

In confirmation of the reality of this animal, our learned author cites Debes's deſcription of Faroe, for the exiſtence of certain iſlands, which ſuddenly appear, and as ſuddenly vaniſh. Many ſeafaring people, he adds, give accounts of ſuch, particularly in the North ſea; which their ſuperſtition has either attributed to the deluſion of the devil, or conſidered as inhabited by evil ſpirits. But our honeſt hiſtorian, who is not for wronging the devil himſelf, ſuppoſes ſuch miſtaken iſlands to be nothing but the *kraken*, called by ſome the *ſea trolden*, or *ſea moſchieſ*; in which opinion he was greatly confirmed by the following quotation of Dr. Hierne, a learned Swede, from baron Grippenhielm; and which is certainly a very remarkable paſſage, viz. "Among the rocks "about Stockholm, there is ſometimes ſeen a tract of "land, which at other times diſappears, and is ſeen "again in another place. Buræus has placed it as an "iſland in his map. The peaſants, who call it *gummars "ore*, ſay, that it is not always ſeen, and that it lies out "in the open ſea, but I could never find it. One Sun"day, when I was out amongſt the rocks, ſounding the "coaſts, it happened that, in one place, I ſaw ſome"thing like three points of land in the ſea, which ſur"priſed me a little, and I thought I had inadvertently "paſſed them over before. Upon this I called to a pea"ſant, to enquire for *gummars ore*; but when he came "we could ſee nothing of it: upon which the peaſant "ſaid, all was well, and that this prognoſticated a ſtorm, "or a great quantity of fiſh." To which our author ſubjoins, "who cannot diſcover that this *gummars ore* "with its points, and prognoſtications of fiſh, was the "*kraken*, miſtaken by Buræus for an iſland, who may "keep himſelf about that ſpot where he *riſes*." He takes the *kraken*, doubtleſs, from his numerous *teſtaculi*, which ſerve him as feet, to be of the polype kind; and the contemplation of its enormous bulk led him to adapt a paſſage from Eccleſ. xliii. 31, 32, to it. Whether by it may be intended the dragon that is in the ſea, mentioned Iſaiah xxvii. 1. we refer to the conjecture of the reader. After paying but a juſt reſpect to the moral character, the reverend function, and diligent inveſtigations of our author, we muſt admit the poſſibility of its exiſtence, as it implies no contradiction; though it ſeems to encounter a general prepoſſeſſion of the whale's being the largeſt animal on, or in, our globe; and the eradication of any long prepoſſeſſion is attended with ſomething irkſome to us. But were we to ſuppoſe a ſalmon or a ſturgeon, the largeſt fiſh any number of perſons had ſeen or heard of, and the whale had diſcovered himſelf as ſeldom, and but in part, as the *kraken*, it is eaſy to conceive, that the exiſtence of the whale had been as indigeſtible to ſuch perſons then, as that of the *kraken* may be to others now. Some may incline to think, ſuch an extenſive monſter would encroach on the ſymmetry of nature, and be over proportionate to the ſize of the globe itſelf: as a little retroſpection will inform us, that the breadth of what is ſeen of him, ſuppoſing him nearly round, muſt be full two thouſand ſix hundred feet (if more oval, or crab-like, full two thouſand) and his thickneſs, which may rather be called altitude, at leaſt three hundred; our author declaring, he has choſen the leaſt circumference mentioned of this animal, for the greater certainty. Theſe immenſe dimenſions, nevertheleſs, we apprehend will not argue concluſively againſt the exiſtence of the animal, though conſiderably againſt a numerous increaſe or propagation of it. In fact, the great ſcarcity of the *kraken*, his confinement to the North ſea, and perhaps to equal latitudes in the ſouth; the ſmall number propagated by the whale, who is viviparous; and by the largeſt land animals, of whom the elephant is ſaid to go near two years with young; all induce us to conclude, from analogy, that this creature is not numerous; which coincides with a paſſage in a manuſcript aſcribed to Sverre king of Norway, as it is cited by Ol. Wormius, in his Muſeum, p 280. in Latin, which we ſhall exactly tranſlate. "There remains one kind, which they call "hafgufe, whoſe magnitude is unknown, as it is ſeldom "ſeen. Thoſe who affirm they have ſeen its body, de"clare, it is more like an iſland than a beaſt, and that "its carcaſe was never found; whence ſome imagine, "there are but two of the kind in nature." Whether the vaniſhing iſland, Lemair, of which captain Rodney went in ſearch, was a *kraken*, we ſubmit to the fancy of our readers. In fine, if the exiſtence of the creature is admitted, it will ſeem a fair inference, that he is the ſmalleſt as well as largeſt in our world; and that if there are larger in the univerſe, they probably inhabit ſome ſphere or planet more extended than our own. Such we have no pretence to limit; and that fiction can deviſe a much greater than this, is evident, from the cock of Mahomet, and the whale in the Bava Bathra of the Talmud, which were intended to be credited; and to either of which our *kraken* is a very ſhrimp in dimenſions.

KRAMERIA, in *Botany*, a genus of the *tetrandria monogynia* claſs; the characters of which are, that it has no calyx; the corolla has four petals; the upper nectarium is divided into three ſegments, and the lower conſiſts of two leaves; the fruit is a dry, echinated, ſingle-ſeeded berry.

KUL, or KOOL, a Turkiſh term, properly ſignifying a *ſlave* or *ſervant*.

Meninſky tells us, the name is given to all the ſoldiers in the Ottoman empire, particularly to thoſe of the grand ſeignior's guard, and the infantry. The captains of the infantry, and thoſe who command the guards are called *kûl kahyaſi*, and the ſoldiers of the grand ſeignior *kapu kûlleri*, i. e. *ſlaves of the court*. Others inform us, that all who hold any places depending on the crown, or receive wages from it, in a word, all who are, in any meaſure, the grand ſeignior's ſervants, take the title of *kûl* or *kool*, i. e. *ſlave*, as more creditable than that of ſubject; even the grand vizir and the baſhaws value themſelves upon it. A *kûl* or ſlave, of the grand ſeignior, has authority to abuſe any who are only his ſervants; but a ſubject, who ſhould affront a *kûl*, or ſlave, would be ſeverely puniſhed. The *kûls* are entirely devoted to the will of the grand ſeignior, and look on it as a kind of martyrdom, that merits heaven, when they die either by his order, or in the execution of his commands.

KUPPER-*Nickel*, in *Natural Hiſtory*, is a reddiſh yellow mineral, containing the ſemi-metal called NICKEL together with iron and cobalt, mineraliſed by arſenic and ſulphur. It is ſometimes of a vitreous texture, ſometimes fine-grained, and ſometimes conſiſting of ſcaly particles.

KURTCHI, an order of ſoldiery among the Perſians.

The word, in its original, ſignifies *army*; and is applied to a body of cavalry, conſiſting of the nobility of the kingdom of Perſia, and the poſterity of thoſe conquerors, who placed Iſmael Sophi on the throne. They are in number about eighteen thouſand men.

Their commander is called *kurtchi baſchi*, which was formerly the firſt poſt in the kingdom; equivalent to a conſtable of France.

KYPHONISM, KYPHONISMUS, or CYPHONISMUS, an ancient puniſhment, which was frequently undergone by the martyrs in the primitive times; wherein the body of the perſon to ſuffer was anointed with honey, and ſo expoſed to the ſun, that the flies and waſps might be tempted to torment him. This was performed in three manners; ſometimes they only tied the patient to a ſtake; ſometimes they hoiſted him up into the air, and ſuſpended him in a baſket; and ſometimes they ſtretched him out on the ground, with his hands bound behind him. The word is originally Greek, and [illegible] κύφων, which ſignifies either the *ſtake* to which the criminal was tied, the *collar* fitted to his neck, or the [illegible] wherewith they tormented him; the Scholiaſt on Ariſtophanes ſays, it was a wooden lock, or [illegible] and that it was called ſo from κύπτω, *to ſtoop* or *bend*, becauſe it kept the tortured in a crooked, bowing poſture. Others take the κύφων for a log of wood laid over the criminal's head, to prevent his ſtanding upright: Heſychius deſcribes the κύφων as a piece of wood, whereon criminals were ſtretched and tormented. In effect, it is probable the word might ſignify all theſe ſeveral things. It was a generical name, whereof theſe were the ſpecies.

Suidas gives us the fragment of an old law, which puniſhed thoſe who treated the laws with contempt, with *kyphoniſm* for the ſpace of twenty days; after which they were to be precipitated from a rock, dreſſed in women's habit.

KYSTIS, Κύστις, in *Anatomy*. See CYSTIS.

L.

L, *EL*, a semi-vowel, or liquid conſonant, making the eleventh letter of the Engliſh alphabet, and always preſerving the ſame ſound.

The *l* is pronounced by applying the tongue to the palate.

Feſtus obſerves, that *l* was frequently uſed among the ancients for *b*, as in *ollibæ* for *olibæ*; for *d*, as *alipe* for *adipe*; for *i*, as *mutila* for *mutica*; for *n*, as *arvilla* for *arvina*, *bello* for *bene*, *colligo* for *conligo*; for *r*, as *fratelles* of *frater*, *balatrones* for *baratrones*; for *ſ*, as *ancille* of *am* and *caſum*, *equiles* for *equiſes*; for *t*, as *equiſelis*, for *equiſetis*, *Thelis* for *Thetis*. See B, T, &c.

The *ll* is a modern contrivance, and was never uſed among ancient Roman authors: they wrote *alum*, not *allium*; *macellum*, not *macellum*; *pulcer*, not *pulcherr*.

The *ll* of the Greeks was ſometimes changed by the Romans into *l*, as in ἀλλομαι, *ſalio*; ἀλλος, *alius*; φολλον, *folium*: *r* has alſo been turned into *ll*; as *hira*, *illa*; *farare*, *fatullare*, &c. and *l* into *n* or *mill*; as *alo*, *anilla*; *malo*, *maxilla*; *velum*, *vexillum*; *d* was alſo uſed for *l*, *n* for *ll*, and *r* for *l*. See R, &c.

L is alſo frequently uſed inſtead of *d*, as in *Ulyſſes*, from the Greek Ὀδυσσεύς, in the Æolic dialect Ὀδυσσεύς. Thus alſo for *dautia*, we ſay *lautia*; for *dacrumæ*, *lacrymæ*, &c. See D.

There are ſeveral people, for inſtance the Chineſe in Aſia, the Illinois in America, &c. who cannot pronounce the *r*, but always change it into *l*. Thus, when any of them have been baptized by the name of *Petrus*, *Franciſcus*, &c. they always pronounce it *Pethus*, *Flanciſcus*, &c. See R.

Among the Saxons the *l* was aſpirated, and the Spaniards and Welſh uſually double it at the beginning of a word, which ſounds nearly the ſame with our *hl* or *ſl*. At the end of a monoſyllable it is always doubled, except after a diphthong. In a word of more ſyllables it is written ſingle. It is ſometimes inſerted before *s*, and founded feebly after it.

The figure of our *L* we borrowed from the Latins, they from the Greeks, and they again from the Hebrews, whoſe *lamed* is much like our *L*, excepting that the angle is ſomewhat more acute.

L, was alſo a numeral letter among the ancients, and is ſtill ſo in the Roman cypherings, ſignifying *fifty*; according to the verſe,

Quinquies L *denos numero deſignat habendos.*

When a daſh was added at the top, thus, $\overline{L}$, it ſtood for *fifty thouſand*.

L was uſed for fifty, being half a C, which ſignified a hundred, and was formerly written thus L, which, according to Paſquier, makes two L.L. the one upright, the other inverted.

The French Louis *d'ors* have a croſs on them, conſiſting of eight *L*'s interwoven, and diſpoſed in form of a croſs.

The letter *L* is marked on the money coined at Bayonne.

The epochas on Greek medals are uſually written with the ancient *lambda*, *L*; which, according to the tradition of the antiquaries, ſtands for Λευκόθεα, a poetical word, unknown in common ſpeech, ſignifying *aurea*, and which it is probable was more uſed in Egypt than Greece.

L as an abbreviature ſtands for Lucius; and *LLS.* for a BEFERCE. In Engliſh, it denotes a pound ſterling.

LA, in the *Italian Muſic*, a ſyllable by which Guido denominated the laſt ſound in each hexachord; if it begins in C it anſwers to our A, if in G to E, if in F to D.

LABADISTS, or LABBADISTS, in *Eccleſiaſtical Hiſtory*, a ſect of religioniſts, followers of the opinion of Jean de Labbadie, who lived in the laſt century, and was contemporary with mademoiſelle Bourignon.

Labbadie was a native of France, who, after having been honourably diſmiſſed, in 1630, from the order of the Jeſuits, to which he belonged, became a member and miniſter of the reformed church, and erected a new community, which, after his death, in 1674, ſettled at Wievert, in North Holland; where it ſoon ſunk into oblivion.

Some of his tenets were, that 1. God could and did deceive men. 2. That in reading the Scriptures greater attention ſhould be given to the internal inſpiration of the Holy Spirit than to the words of the text; that the Scripture was not ſufficient to lead men to ſalvation, without certain illuminations and revelations from the Holy Ghoſt; and that the efficacy of the word depended upon him that preached it. 3. That baptiſm ought to be deferred till mature age. 4. That the good and the wicked entered equally into the old alliance, providing they deſcended from Abraham, but that the new admitted only ſpiritual men. 5. That the obſervation of Sunday was a matter of indifference. 6. That Chriſt would come and reign a thouſand years on earth. 7. That the euchariſt was only a commemoration of the death of Chriſt; and that though the ſymbols were nothing in themſelves, yet that Chriſt was ſpiritually received by thoſe who partook of them in a due manner. 8. That a contemplative life was a ſtate of grace, and of divine union during this life, the ſummit of perfection, &c. 9. That the man whoſe heart was perfectly content and calm, half enjoys God, has familiar entertainments with him, and ſees all things in him. 10. That this ſtate was to be come at by an entire ſelf-abnegation, by the mortification of the ſenſes and their objects, and by the exerciſe of mental prayer. He alſo maintained, that the faithful ought to have all things in common, and that there is no ſubordination or diſtinction of rank in the church of Chriſt. It is ſaid that the Browniſts, and afterwards the Quakers, offered to connect themſelves with this ſect, but were rejected. See Journ. des Sçavans for October, 1727, where we have ſome account of Labadie and his followers, which were moſtly women; and with ſome of whom, it has been ſaid, he took criminal liberties.

LABARIFERI, among the *Romans*, ſtandard bearers, who carried the LABARUM.

LABARUM, in *Antiquity*, the banner or ſtandard borne before the Roman emperors in the wars.

The *labarum* conſiſted of a long lance, with a ſtaff at the top, croſſing it at right angles; from which hung a rich ſtreamer, of a purple colour, adorned with precious ſtones.

Till the time of Conſtantine it had an eagle painted on it; but that emperor, in lieu thereof, added a croſs, with a cypher expreſſing the name of Jeſus, and thoſe fifty of the braveſt men in his guards to bear it on their ſhoulders, each in his turn.

This ſtandard the Romans took from the Germans, Dacæ, Sarmatæ, Pannonians, &c. whom they had overcome.

The name *labarum* was not known before the time of Conſtantine; but the ſtandard itſelf, in the form we have deſcribed it, abating the ſymbols of Chriſtianity, was uſed by all the preceding emperors.

Some derive the word from *labor*, as if this finiſhed their labours; ſome from λαβαειν, *recurvum*, *picty*; others from λαβαρος, *celer*; and others from λαμπρα, *ſplis*.

The *labarum* has afforded very ample matter for criticiſm, and has been diſcourſed of by Voſſius, Alciatus, Cujas, Gyraldus, Lipſius, Meurſius, Voſſius, Hoffman, Valois, Du-Cange, &c.

LABDACISM, Λαβδακισμος, in *Rhetoric*, the too frequent repetition of the letter L, as *ſol et luna lucc lucebunt*, and *alba levi lallea*.

LABDANUM, in the *Materia Medica*. See LADANUM.

LABEL, a long thin brass ruler, with a small tight at one end, and a center-hole at the other; commonly used with a tangent line on the edge of a circumferentor, to take altitudes, &c.

LABEL, in *Law*, is a narrow slip of paper, or parchment, affixed to a deed or writing, in order to hold the appending seal. Any paper annexed by way of addition, or explication, to any will or testament, is also called a *label*, or CODICIL.

Among apothecaries likewise, the slip of paper round their phials, containing directions how to use the medicine, is called a *label*.

LABEL, in *Heraldry*, a kind of addition to the arms of the heir or first son, to distinguish him from the others. See FILE, and *Tab. Heraldry, fig.* 23.

The *label* is esteemed the most honourable of all differences; and is formed by a fillet usually placed in the middle, and along the chief of the coat, without touching its extremities. Its breadth ought to be a ninth part of the chief.

It is adorned with pendants somewhat like the drops under the triglyphs in the Doric frieze. When there are above three pendants, the number must be specified in blazoning. There are sometimes six.

The *label* is the only difference allowed on the coats of arms belonging to any of the royal family.

LABELLED-*line*, in *Heraldry*, a term used by some to express the line in certain coat arms, called more usually *indented* or *champaigne*. Others apply the same word to express the paire or dove-tail line, called also the *enclaveline* by Morgan. It somewhat resembles the joint called a *dovetail* by our joiners, and its points, as they proceed from the ordinary, whether chief or fess, resemble the ends of *labels*. See URDEE and PATEE.

LABEO, in *Ichthyology*, a name given by the old Latin writers to the fish usually called *cheilon* and CHELON.

LABER, a word found in Serapion, and used there as the name of an aromatic drug. The commentators have been much perplexed to find the reason or etymology of the word, as it appears no where else in the writings of the ancients. It seems to be no other than a wrong spelling of the word *saber* or *sabar*, sometimes also written by the Arabians *ceber*, which is a name of the lignum aloes.

LABIA, in *Anatomy*. See LIPS.

Depressor LABIORUM. See DEPRESSOR.

Elevator LABIORUM. See ELEVATOR.

LABIAL, a term in the French law, used in the same sense with ORAL.

LABIAL *letters*, among *Grammarians*, are those whose pronunciation is chiefly effected by the motion of the lips. By which they stand contradistinguished from PALATAL, DENTAL, GUTTURAL, &c. letters.

LABIAL *offerings* are such as are only made by word of mouth, or even by writing, where there is no valuable consideration. In courts of equity these are not regarded.

LABIATE *flowers*, from the word *labium*, a *lip*, is a term used for a very large series of flowers; the distinctions of which are, that they are monopetalous, and are in their lower part formed into a pipe or narrow tube, and in their upper become widened into one or two lips. The cup of these flowers consists of one leaf, and is usually tubular, and resembles a paper cone; and their pistil is surrounded with four embryos, which ripen into a fruit, composed of four seeds, and kept inclosed in the cup. By this they are distinguished from the perfonated flowers, whose fruit is an oblong capsule; and they differ from the rotated flowers of borrage, and the like, in that they have some sort of resemblance to the opening of the mouth of some animals. See *Tab.* VIII. *of Botany, Class* 4. See FLOWER.

LABIATED *leaf*. See LEAF.

LABINÆ, in *Natural History*, a term used by the authors who have written of Switzerland, and other mountainous countries, to express those vast masses of snow, which sometimes fall from the hills and bury houses, or even whole towns; and when hardened by the frosts, as is often the case, into solid substances, they overthrow woods, villages, and whatever stands in the way of their course, as they roll down the steep sides of the precipices in their way. Some authors have also extended the word to a larger sense, and made it express the falling of vast rocks, or parts of mountains, and their rolling down in the same manner into the flat country: this is a mischief very frequent in the same places, after frosts, and often very fatal.

LABIUM *superius attollens*, in *Anatomy*, a name given by Spigelius to the muscle, called by Albinus, Winslow, and others, *zygomaticus major*.

LABORANT, in *Chemistry*, the person that attends on, and works under a chemist, while he is about any process or experiment.

LABORATORY, or ELABORATORY, the chemists workhouse, or the place where they perform their operations; where their furnaces are built, their vessels kept, &c.

In general, the term *laboratory* is applied to any place where physical experiments, and operations in pharmacy, chemistry, pyrotechnia, &c. are performed.

Dr. Shaw, who has taken great pains to bring the study of chemistry more into use in England than it has hitherto been, has explained the easiest of its operation in general, and attempted a means of making its practice less expensive, by introducing in the place of that vast number of furnaces, and other contrivances, figured and described by the generality of writers on the subject, a *portable laboratory*, by means of which alone all the chemical operations may be commodiously performed. This *laboratory*, fitted for its several purposes, is figured in the plate of chemical furnaces and vessels, to which we refer the reader. See *Tab.* IV. *of Chemist.* N° 82—88. seq. Its contrivance is such, that not only complete courses of chemical experiments and operations may be commodiously performed by its means, but all the medicines may be prepared in such quantities, as to supply not only the demands of a family, but of an apothecary's shop, in moderate business. The first person who planned out this sort of furnace was Beecher; and the scheme executed by Dr. Shaw is an improvement on that attempt. This *laboratory* consists of two parts beside the furnace; these are the apparatus and the materia medica. The apparatus may be divided into the remote and immediate, or, in other words, such as are preparatory to the operations, and such as are actually employed in them. The remote apparatus consists of scales, weights, and measures; also mortars, sieves, rasps, files, hammers, sheers, and forceps. Next to these are the instruments used in the management of the fire, as shovels, hooks, tongs, and blow-pipes; likewise for charging the vessels with the subject matters of the operations, as shells, horns, tin-plates, brushes, hares feet, spoons, and spatulas; also rounds for setting glasses upon, and for emptying their contents, &c. hooked tongs, cones, ingots, basons, funnels, and Bore-glasses, furnished, according to the nature of the things to be kept in them, with common cocks, wax Stoppels, and glass stoppels; and for tying down of these, bladders, leathers, and the like. In the last place come the instruments for making certain utensils, as moulds for muffles, tests, crucibles, and melting-pots, and iron rings for cutting glasses, and the necks of retorts. The more immediate apparatus, or that employed in the operations themselves, consists of vessels containing the subjects to be wrought upon, particularly glass eggs, and bodies for digestion; retorts and receivers for distillation, blind heads for bodies in sublimation; stone-pans and cut-glasses for evaporation; peculiar stout receivers and glasses for separation; strainers for percolation; paper for filtration; muffles and tests for cupellation; crucibles for melting; pots for cementing; and lutings to close the junctures of the vessels, whenever necessary. For the materia chemica, see MATERIA *chemica*.

The furnace has four principal parts: 1. The cover. 2. The ring. 3. The body. And, 4. The foot. The general office and use of the cover is to check, suppress, and throw back the heat and flame, that the fuel may not waste itself too fast, as it otherwise would do to very little purpose in many of the operations; for the action of the fire being not momentary but successive, the more it is kept in, and directed upon the subject, the more it is able to perform its effect, and that with the less expence or destruction of it. In order to increase the draught to the fire, and urge the air more forcibly through the body of the fuel, there is a moveable funnel or chimney, which may occasionally be fixed to the orifice, in the top of the cover left for that and many other uses. See the figure, ubi supra. The ring is the place or seat of many operations. The body to be worked upon by the fire is frequently lodged in it; and in other cases, it helps to enlarge the furnace, and receive the couple of operations it could not otherwise perform. The body of the furnace serves to contain the fuel, and is the common seat of the operations by the fire, in the running metals from their ores; and in these, and many other like cases, it performs the office of a crucible as well as fire-place, and contains the subject mixed along with the fuel, as supra cited at the smelting-house. To this body there belong three several grates, which may be placed at different heights therein, according to the nature of the operation, and the distance required between the subject and the fire. Lastly, the foot is of two kinds, and is not only of use in supporting the rest of the parts, but it receives the ashes of the fuel, and the melted matter that may, in any of the operations, run down from the ores of metals; or, on other the like occasions,

occasions, when the fire liquidates any thing above. The more immediate appurtenances of this furnace are fuel and bellows. The general fuel is to be charcoal; or, as there is a contrivance for a vent or flue in the body of the furnace, common sea-coal may be employed, and the smoak directed up the chimney of the room, in which the furnace is to ſtand. The ſtructure of this furnace is alſo very well fitted for a lump, which is a ſort of heat, highly convenient for ſome curious digeſtions and calcinations; and by this means thoſe operations, which would otherwiſe require an athanor, may be conveniently performed, and that in the moſt accurate manner.

The number of chemical proceſſes that may be performed by this furnace is not eaſily reckoned up; but it may not be improper to add an account of the ſeveral ſtates into which it is to be put for the performing them.

The moſt ſimple ſtate of the furnace is a combination of its two lower parts, the body and the foot. When theſe are put together, it is fit for fuſion by the naked fire, where the matter to be melted is to be mixed among the fuel; as for inſtance, in the running of the ores of lead, tin, or iron, which may thus, in the quantity of many pounds at a time, be ſeparated from their droſs, and purged for uſe, as exactly as at the mine-works, or ſmelting-houſes, either with the aſſiſtance of the bellows, or without, as the nature of the ore requires. By barely placing a grate in the middle of the body, the inſtrument becomes a melting-furnace for a crucible, wherein all the operations that require a fire of fuſion, animated either by the air, or bellows, are performable with ſuch advantages, as cannot be had in the common wind or blaſt-furnaces made for this purpoſe. When only the body of the furnace with its middle grate is ſet upon the foot, it anſwers all the purpoſes of a ſhop-furnace, uſed by the apothecaries for decoction, inſpiſſation, extraction, and the like purpoſes, where a naked fire only is required; and certain diſtillations and ſublimations may alſo be performed conveniently by it.

It may in this ſtate alſo be conveniently made to ſerve the purpoſes of a *balneum Mariæ*, an aſh-heat, a ſand-heat, or a ſtill ſtronger one for digeſtion and ſublimation, by only ſetting on it in this ſtate a veſſel of water, or one filled with aſhes, ſand, or iron filings; and thus ſeveral operations, requiring the ſame kind of heat, may be carried on at the ſame time. If inſtead of a common pan or veſſel to hold water, ſand, &c. the ring, or third part of the furnace, be ſet on, furniſhed with its ſet of pots, the whole is then a furnace fitted for that ſort of diſtillation called *diſtillation in capella vacua*, where the retorts are contained in the cavity of the pots, and locked down therein without any viſible meſſium between. By this means many operations may be performed in the diſtillation and ſeparation of bodies, that could not be worked upon to ſo much advantage by any other method; particularly, the rectification of the ſtrongeſt acid ſpirits is very eaſily and conveniently performed this way at very little expence.

If an iron pan be placed in the room of the ring juſt mentioned, the inſtrument is then a calcining furnace, where ores of metals may be roaſted; and lead, antimony, and the like bodies, may be conveniently reduced to aſhes.

If the loweſt grate be uſed inſtead of the middle one, then either a cold ſtill, or, as it is generally called, a hot one, may be put into the body, and worked in the common manner with its head and refrigeratory. Thus all the cordial waters may be made, ſpirits may be rectified, and the eſſential oils diſtilled by the ſame means, as well as by the common fixed ſtills.

The laſt part, or cover of the furnace, may ſometimes be applied to the ring, ſometimes only to the body of the furnace without the ring. The inſtrument in this caſe becomes a proper reverberatory furnace, and is uſeful for cementation, cupellation, and the aſſaying of ores; and for diſtilling with a fire of ſuppreſſion, that is, where the fire is placed above as well as below the ſubject, and the veſſel that contains it.

A furnace of this nature has numerous advantages, not only over all the chemical furnaces in common uſe, but even over thoſe of the moſt celebrated ſtructure and contrivance, deſcribed by authors on particular occaſions, not excepting thoſe of Glauber and Vigani. Thoſe nicely contrived furnaces are generally adapted to ſome few particular purpoſes, and yet this eaſy kind anſwers in experiment thoſe very purpoſes better; and at the ſame time is of general uſe on all the other occaſions of chemiſtry. Experience has ſhewn, that it is better for the various uſes of Glauber's philoſophical furnaces, than thoſe very furnaces themſelves, though made for theſe very purpoſes; and for the higher operations, as they are called, of metallurgical chemiſtry. For example, to obtain a pure ſpirit of ſalt in plenty, Glauber orders the ſalt to be thrown upon the fire, and has contrivances to catch the riſing vapour; but this is a tedious way, and turns to very little account in practice, nor is the matter much improved by quenching the coals in a brine of ſea-ſalt, and afterwards burning them for their fume. But all that can be expected from theſe aukward contrivances, may be had commodiouſly from the furnace here deſcribed, where the fire being animated by bellows, cauſes the fire to burn more free, and the fuel to yield the ſpirit it was impregnated with much more quickly and eaſily, than in the furnace contrived by that author for the purpoſe, while the fuel is ſupplied by the door, without any diſturbance to the operation. Shaw's Eſſay on a Portable *Laboratory*.

There are many other curious philoſophical experiments, which can be no way ſo well done as with this kind of furnace, and many ſcarce at all without it. It is excellently fitted alſo for enamelling, making of paſtes, ſtaining of glaſs, and making the artificial gems; and beſide theſe, and a number of other curious uſes, it is extremely well fitted for all the common purpoſes of fires. Any artizan who requires fire, in whatever manner, in his buſineſs, may contrive to apply it in this manner as he will. The offices of a common ſtove in a kitchen may alſo be very well ſupplied by it, and the warming a room or vault is as well done by it, as by any of the common contrivances of ſtoves, ovens, and other things, made purpoſely for that uſe.

The outer caſe of the furnace is to be made of good plate-iron of a conſiderable thickneſs, formed in ſeparate pieces of the figures expreſſed in the plate, and its ſize may be ſuch as the operator chooſes; obſerving only a due proportion in its ſeveral parts. The inner ſides of all the parts muſt be lined, at leaſt an inch thick, with a proper LUTE, which muſt be carefully laid on, and gently dried, the cracks which happen in the drying being filled up with more of the ſame luting. See *Portable* FURNACES.

LABORATORY *of an hoſpital*, is a tent where the fire-workers and bombardeers prepare their works, drive their fuſees, fix their ſhells and carcaſes, make quick-match, &c.

LABOUR, in a general ſenſe, imports the exertion of human ſtrength in the performance of any kind of work. See LAND.

Labourers conſpiring together, concerning their work or wages, ſhall forfeit 10*l*. for the firſt offence, 20*l*. for the ſecond, &c. and if not paid, to be ſet on the pillory. Stat. 2 & 3 Edw. VI. cap. 15. Juſtices of peace, and ſtewards of leets, &c. have power to hear and determine complaints relating to non-payment of labourers wages. 4 Edw. IV. cap. 1. And labourers taking work by the great, and leaving the ſame unfiniſhed, unleſs for non-payment of wages, or when they are employed in the king's ſervice, &c. are to ſuffer one month's impriſonment, and forfeit 5*l*. The wages of labourers are to be yearly aſſeſſed for every county, by the ſheriff and juſtices of peace, in the Eaſter ſeſſions; and in corporations by the head officers, under penalties. 5 Eliz. cap. 4. And the ſheriff is to cauſe the ſaid rates and aſſeſſments of wages to be proclaimed. 1 Jac. I. cap. 6. All perſons fit for *labour* ſhall be compelled to ſerve by the day, in the time of hay or corn harveſt; and labourers in harveſt time may go to other counties, having teſtimonials. From the middle of March to the middle of September, labourers are to work from five o'clock in the morning till ſeven or eight at night, being allowed two hours for breakfaſt and dinner, and half an hour for ſleeping in the three hot months; and all the reſt of the year from twilight to twilight, excepting an hour and a half for breakfaſt and dinner, on pain of forfeiting one penny for every hour's abſence. 4 Eliz. If any labourer ſhall make an aſſault upon his maſter, he ſhall ſuffer as a ſervant making ſuch aſſault.

LABOUR, likewiſe, is uſed to denote the pain which women endure in giving birth to their offspring; and is uſually divided into natural, difficult, and preternatural. For the progreſs of a natural *labour*, ſee DELIVERY.

A labour is ſaid to be difficult, when the infant is not brought into the world in the uſual time, that is, in an hour or two; but for certain cauſes is retained longer than ordinary, and cannot be brought away without difficulty, and the greateſt care and diligence. The moſt direct and immediate cauſes of accidents of this kind are, firſt, a bad conformation of the body, as in deformed women; and eſpecially when the bones of the pelvis, the os coccygis, and the os ſacrum, in particular, are preternaturally formed, by which means the pelvis is frequently rendered ſo narrow as not to admit the hands. Secondly, the age of the patient; when, for inſtance, women are either too young and tender, or too old, eſpecially

cially in their firſt labour. Thirdly, when they are too timorous, delicate, or abound too much in blood. Fourthly, when their labour is too much haſtened, before nature concurs, and offers her aſſiſtance; or when the waters are either too ſoon diſcharged, or too long retained. Fifthly, when the patients, not before accuſtomed to ſuch circumſtances, refuſe to aſſiſt their genuine and legitimate pains by their own efforts. The more of theſe, or ſuch cauſes concur, ſo much the more difficult is the *labour*, and the danger is alſo proportionable. When the head of the child is long confined in the pelvis, it is equally dangerous to the mother and the child; for by its preſſure againſt the ſoft parts, it may ſtop the circulation, and bring on inflammation and gangrene, which would prove certain death to the mother, and likewiſe to the child, by its affecting the brain. When this kind of danger is apprehended, the forceps muſt be uſed.

Preternatural *labour* is that in which the legs or breech are delivered firſt, and the body and head laſt. *Labours* of this kind are more or leſs difficult, according to the poſition of the child, and the contraction of the uterus. They are uſually divided into three claſſes: 1. When the lower parts of the child, as the feet, knees, or breech, preſent. 2. When it is known that the preſentation is wrong, and the midwife has the advantage of turning the child immediately, on breaking the membranes, by means of the waters. 3. When the child preſents wrong, and the uterus is cloſely contracted, the advantage of the water being loſt. When it is known that the breaſt, belly, ſhoulders, or any part but the head, feet, knees, or buttocks, preſent, and the membranes have ſomewhat protruded, let them be broke; and by immediately introducing the hand, let the feet be brought into the paſſage, and thus let the child be delivered, as when the feet preſent. In other caſes of preternatural *labour*, the method of delivery depends upon the part of the child which firſt preſents itſelf.

LABOUR, in *Sea-Language*, is uſed when a ſhip rolls or toſſes much in a turbulent ſea.

LABRISULCIUM, in the *Art of Healing*, is a chap in the lip, or the ſame with CHEILOCACE; and is a ſcrophulous ſymptom.

The chaps upper lip, as it is an attendant on the ſtrumæ, is beſt cured by the ſame internal remedies uſually preſcribed to alter and rectify this particular dyſcraſy of the blood, and its ſecreted juices; which, together with mercurial purgation, oftentimes takes down the ſwelling, at leaſt for a time; till by getting a freſh cold, or ſome other treſpaſs in the non-naturals, a new fluxion ariſes, and the part ſwells up again.

The chap, or cleft, may be anointed with oil of almonds, ſpermaceti, ointment of tutty, or Turner's cerate of lapis calaminaris.

LABRUS, in *Ichthyology*, the name of a genus of fiſh, the characters of which are theſe; they are of the acanthopterygious tribe; the branchioſtege membrane on each ſide contains ſix ſlender and flat bones, when the fiſh is full grown; but in the young ones, five only can be counted; the teeth are large, and are placed in the jaws, and on three bones in the fauces; the upper ones hard, and two in number, the lower one ſingle; the palate and tongue are ſmooth; there are thick and fleſhy lips covering the teeth; the membrane of the back-fin contains in its fore-part double rays, ariſing from each baſe of theſe two; the one is prickly, the other ſoft and inoffenſive; the colour is generally beautiful, and in moſt of the ſpecies elegantly variegated; the tail is generally undivided; the ſcales are large, ſoft, and ſmooth; and there are no appendices to the pylorus. The ſpecies of this genus, enumerated by Artedi, are ten.

In the Linnæan ſyſtem this is a genus of the thoracic order, comprehending forty-one ſpecies.

The word *labrus* is truly Roman, and is uſed in the ſame ſenſe by Ovid and others, being probably derived from the word *labra*, *lips*; this fiſh having remarkably thick and prominent lips.

LABRUSCA, in *Botany*, a name uſed by the old authors for black bryony.

LABURNUM, in *Botany*. See *Baſe-tree* TREFOIL.

LABUYO, in *Natural Hiſtory*, a name given by the inhabitants of the Philippine iſlands to a bird very common among them, and called by us the UROGALLUS.

LABYRINTH, Λαβύρινθος, among the *Ancients*, was a large and intricate edifice cut out into various iſles and meanders, running into each other, ſo as to render it difficult to get out of it.

There is mention made of four celebrated *labyrinths* among the ancients, ranked by Pliny in the number of the wonders of the world; viz. the Cretan, Egyptian, Lemnian, and Italian.

That of Crete is the moſt famed; it was built by Dædalus, for king Minos, on the model o that of Egypt; and it was hence that Theſeus made his eſcape by means of Ariadne's clue.

That of Egypt, according to Pliny, was the oldeſt of all; and was finiſhing in his time, after having ſtood 3600 years. He ſays it was built by king Peteſuchus, or Tithoes; but Herodotus makes it the work of ſeveral kings: it ſtood on the banks of the lake Mœris, and conſiſted of twelve palaces, in which the twelve kings of Egypt aſſembled to tranſact affairs of ſtate and religion, containing three thouſand apartments. See a plan and deſcription of this *labyrinth*, in the preſent ſtate of it, in Pococke's Hiſt. of the Eaſt, vol. i. p. 61, &c. See alſo Perry's View of the Levant, p. 381, &c.

That of Lemnos was ſupported by columns of wonderful beauty; there were ſome remains of it at the time when Pliny wrote. That of Italy was built by Porſenna, king of Hetruria, for his tomb.

LABYRINTH, in *Anatomy*, denotes the ſecond cavity of the internal EAR, which is formed or excavated out of the os petroſum; and is thus called, as having ſeveral windings in it.

Dr. Vieuſſens obſerves, that the bone, out of which the *labyrinth* is dug, is white, hard, and very compact; that the ethereal matter of ſounds laden with impreſſions ſtriking againſt its ſide, may loſe little or nothing of its motion, but communicate it entire to the nerves of the ear. See HEARING, SOUND, &c.

LABYRINTH, in *Gardening*, is a part of the ground ſo planted and diſpoſed, as to render it difficult, when any one is in it, to find the way out; and in the attempting to get out, there are to be as many ſtops and diſappointments laid in the way as poſſible: the center alſo is to be made difficult to be found. There are two general ways of making them; the firſt is with ſingle hedges, and this is what has been moſt practiſed in England; and this may be beſt where there is but a ſmall ſpot of ground allowed for the making them; but where there is room enough, the double hedges are much the moſt eligible; and theſe are beſt of all, when there is a wood-work between them. The walks in *labyrinths* ſhould be gravelled, and ſhould by no means be made too narrow. Theſe are to be ſet with iron bars, and the paliſades ought to be ten, twelve, or fourteen feet high. *Labyrinths* are only proper for large gardens; and the moſt in the world is ſaid to be that of Verſailles. That at Hampton-court is well known.

LAC, *milk*. See MILK.

LAC *ammoniaci* is formed by triturating gum ammoniac in ſimple penny-royal water, in ſuch proportion that four ſpoonfuls, or two ounces, of the emulſion, contain thirty grains of the AMMONIAC. Some have diſſolved it in vinegar of ſquills.

LAC *lunæ*. Dr. Plott gives this foſſil as a mark of good lime-ſtone; but it has been obſerved, that two quarries in Ireland, where *lac lunæ* was found, were of building ſtone, but would not burn into lime. Phil. Tranſ. N° 477. § 9.

There are many varieties of this mineral, differing in their texture and colour. It is found in many parts of Europe, and alſo in Aſia and America. Many of the Engliſh quarries in Oxfordſhire, Glouceſterſhire, Northamptonſhire, and Derbyſhire, afford conſiderable quantities of it. It adheres to the roofs and walls of grottoes and caverns, and is lodged in the fiſſures of ſtrata of ſtone, ſometimes in form of a farinaceous powder, and ſometimes concreted into maſſes. Its ſurface is rough and duſky; it colours the hands, adheres to the tongue, melts readily in the mouth, without grittineſs, yields an inſipid taſte, and raiſes an ebullition in water, which ſoon diſſolves it into a fine white powder. See AGARIC.

LAC *ſulphuris*. See SULPHUR.

LAC *virginale*. See *Virgin's* MILK.

LAC *virginis*. See VIRGIN's *milk*, and BALAUSTIN.

LACCA, *ſtick-lac*, improperly called [illegible] is a ſort of hard, red, brittle, clear, and [illegible] ſubſtance, brought from Malabar, Bengal, and [illegible] uſed in dyeing ſcarlet, and in painting, making [illegible] ſpirit varniſhes, &c.

Authors differ as to the production of this [illegible] F. Tachard, who was on the ſpot, tells us, [illegible] of little ants, fixing themſelves on the branches [illegible] ſeveral trees, leave behind them a reddiſh moiſture, which, lying expoſed to the air and ſun, hardens in five or ſix days time, and becomes *lacca*. Some imagine that it is not the production of the ants, but a juice which they draw out of the trees, by making little inciſions in it; and others ſay, that the trees where the *lacca* is found do yield a gum; but that it is of a very different nature from the *lacca*.

The ants, they tell us, act here in quality of bees, and the *lacca* is their wax. They work it in eight months

in the year, and the reſt of the time lie by, becauſe of the rains.

Lemery, having examined the gum *lacca* chemically, judges it to be a mean mixture between a gum and a reſin, and more abundant in ſalt than oil.

Mr. Geoffroy, examining the gum *lacca*, found it to be a kind of comb, ſuch as the bees, and ſome other inſects, are accuſtomed to make. Upon breaking it into pieces, it appeared divided into a great number of alveoli, or little cells, of an uniform figure, and which he thinks plainly ſhew that it never oozed from trees. Theſe cells are not mere excrements, as ſome imagine; but are intended for ſomething to be depoſited in them, and accordingly are found to contain little bodies, which the firſt obſervers took for the wings, or other parts of the inſects that produced the *lacca*. Theſe little bodies are of a beautiful red colour; and, when broken, make a powder as fine as cochineal. It is moſt probable theſe cells are deſtined to lodge the young brood, as thoſe of the bees; and that theſe little carcaſes are the embryos of inſects, or perhaps their ſkins.

There are ſeveral ſorts of *lacca*; that mentioned in the laſt paragraph is the natural, being a kind of wax depoſited either on the branches of the trees, or on ſticks faſtened in the earth for that purpoſe, and thence called *ſtick-lac*. When it is prepared, thoſe kinds of dry cells are not ſeen. If the *lac* be ſeparated from the ſticks to which it adheres, groſly powdered, and deprived of its colour by digeſtion with menſtruums, it is called *lac lac*; and when the *ſtick-lac* is freed from its impurities, by melting it over a gentle fire, and formed into cakes, it is called *ſhell-lac*. The grains, or plates, thus formed by liquefaction, and robbed of great part of the animal tincture, ſeem to be of an intermediate nature between that of wax and reſins, or to partake of the nature of both; they crumble on chewing, and do not ſoften or ſtick together again; laid on a red-hot iron, they inſtantly catch fire, and quickly burn off, with a ſtrong and not diſagreeable ſmell; diſtilled, they yield, like wax, an acid ſpirit, and a butyraceous oil; alkaline lixivia, and volatile alkaline ſpirits, diſſolve them into a purpliſh liquor; they diſſolve alſo, by the aſſiſtance of heat, in rectified ſpirit of wine, communicate to it a yelloviſh or browniſh red colour, an agreeable ſmell, and a bitteriſh, ſubaſtringent, not unpleaſant, taſte. The *lac* in ſubſtance, whether entire, or freed from ſo much of its colouring matter as boiling water is capable of extracting, has no manifeſt taſte or ſmell. M. Geoffroy reckons ſix or ſeven different kinds; beſides which, there are ſeveral paſtes uſed by the painters, that go by this name, or by that of *laque*. This gum boiled in water with acids makes a beautiful red dye.

To prepare the *lacca* for uſe in dyeing, they firſt ſeparate it from the branches to which it adheres, pound it in a mortar, and throw it into boiling water; and when the water is well dyed, they pour on freſh, till ſuch time as it will tinge no more. Part of the water thus tinged is evaporated in the ſun; after which the thickened tincture is ſtrained through a linen cloth.

The colour given by *lac* is leſs beautiful, but more durable, than that given by cochineal. To render the colouring matter of the *lac* diffuſible in water, ſo as to be applied to the ſtuffs to be dyed, Mr. Hellot directs the following procedure. Let ſome powdered *gum-lac* be digeſted for two hours in a decoction of ſoot-free-ſtone, by which a fine crimſon colour is given to the water, and the gum is rendered pale or throw-coloured. To this tincture, poured off clear, let a ſolution of alum be added; and when the colouring matter has ſubſided, let it be ſeparated from the clear liquor, and dried. It will weigh about one-fifth of the quantity of *lac* employed. This dried feculæ is to be diſſolved or diffuſed in warm water, and ſome ſolution of tin is to be added to it, by which it acquires a vivid ſcarlet colour. This liquor is to be added to a ſolution of tartar in boiling water; and thus the dye is prepared.

The method of obtaining the fine red *lac* uſed by painters from this ſubſtance, is by the following ſimple proceſs. Boil the *ſtick-lac* in water, filtre the decoction, and evaporate the clear liquor to a conſiſtence over a gentle fire. The occaſion of this eaſy ſeparation is, that the beautiful red colour, here ſeparated, adheres only ſlightly to the outſides of the ſticks, broke off the trees along with the *gum-lac*, and readily communicates itſelf to boiling water. Some of this ſticking matter alſo adhering to the gum itſelf, it is proper to boil the whole together; for the gum does not at all prejudice the colour, nor diſſolve in boiling water: ſo that after this operation the *gum* is as fit for making ſealing-wax as before, and for all other uſes which do not require its colour.

A tincture of *gum-lac* may be thus prepared. Take two ounces of *gum-lac*, reduce it to a fine powder, and make it into a ſtiff paſte with oil of tartar *per deliquium*; ſet this in an open glaſs to dry by a gentle heat, then remove it to the open air, that it may relent and grow ſoft, then dry it again, and repeat this two or three times, at the end of which the hard body of this reſin will be found reſolved into a purple liquor. This may yet again be dried, and when dried muſt be reduced to powder, which powder will afford a fine ſtrong tincture to ſpirit of wine, being boiled in it in a tall glaſs in a ſand-heat for two or three hours. And by this proceſs ſtrong tinctures may be made from myrrh, amber, gum, juniper, &c. which will yield no tincture of ſtrength to ſpirit of wine alone, if treated in the uſual way.

A ſpirituous tincture of *ſtick-lac* has been ſometimes given as a mild reſtringent and corroborant in female weakneſſes, and in rheumatic and ſcorbutic diſorders. But the principal medicinal uſe of this concrete is as a topical corroborant and antiſeptic, in laxities and ſcorbutic bleedings, and exulcerations of the gums. Some employ for this purpoſe a tincture of the *lac* in alum water; others, a tincture made in vinous ſpirits, impregnated with the pungent antiſcorbutics. The college of Edinburgh directs an ounce of the powdered *lac*, with half an ounce of powdered myrrh, to be digeſted in a ſand-heat, for ſix days, in a pint and a half of ſcurvy graſs.

The *gum-lac* has been lately uſed as an electric, inſtead of glaſs, for ELECTRICAL *machines*. See LACHRIE, LAKE, and VERNISH.

LACCA, *artificial*, or LAQUE, is alſo a name given to a coloured ſubſtance, drawn from ſeveral flowers; as the yellow from the flowers of the juniper, the red from the poppy, and the blue from the iris or violet.

The tinctures of theſe flowers are extracted by digeſting them ſeveral times in aqua vitæ, or by boiling them over a ſlove fire in a lixivium of pot-aſhes and alum.

An *artificial lacca* is alſo made of Brazil wood, boiled in a lixivium of the branches of the vine, adding a little cochineal, turmeric, calcined alum, and arſenic, incorporated with the bones of the cuttle-fiſh pulverized, and made up into little cakes, and dried.

If it be to be very red, they add the juice of lemon to it; to make it brown, they add oil of tartar.

Dove-coloured, or columbine *lacca*, is made with Brazil of Fernambuc, ſteeped in diſtilled vinegar for the ſpace of a month, and mixed with alum incorporated in cuttle-fiſh bone. For other proceſſes, ſee LAKE and MADDER.

LACCIA, in *Ichthyology*, a name given by Paulus Jovius to the SHAD, or, as we ſometimes call it, the mother of the pilchards.

LACCOPEDON, a word uſed by the old medical writers to expreſs the lax part of the ſcrotum.

LACCUS, Λάκκος, among the Greeks, a ditch or trench uſed inſtead of an ALTAR, when ſacrifices were to be offered to the ſubterranean or infernal gods.

LACE, in *Commerce*, a work compoſed of many threads of gold, ſilver, ſilk, or linen, interwoven the one with the other, and worked upon a pillow with ſpindles, according to the pattern deſigned; the open work being formed with pins, which are placed and diſplaced as the ſpindles are moved. See GOLD *thread*.

The importation of gold and ſilver *lace* is prohibited.

LACE, *bone*, a *lace* made of fine linen thread or ſilk, much in the ſame manner as that of gold and ſilver. The pattern of the *lace* is fixed upon a large round pillow, and pins being ſtuck into the holes or opening in the pattern, the threads are interwoven by means of a number of bobbins made of bone or ivory, each of which contains a ſmall quantity of fine thread, in ſuch a manner as to make the *lace* exactly reſemble the pattern. There are ſeveral towns in England, and particularly in Buckinghamſhire, that carry on this manufacture; but vaſt quantities of the fineſt *laces* have been imported from Flanders.

The duties on foreign *bone lace* are as follow. *Bone lace* of thread, the dozen yards, pays on importation 15*s.* 4¼*d.* and drawn back on exportation 13*s.* 6*d.* Plain, or antler *lace* of thread, the groſs, pays 3*s.* 10·½*d.* Silk *bone-lace* the pound, containing ſixteen ounces, pays 11*l.* 10*s.* 10¾*d.*

LACE is alſo uſed for a kind of chord made of ſilk or cotton, chiefly uſed in lacing women's ſtays.

LACEDÆMONIUM *marmor*, in the *Natural Hiſtory of the Ancients*, the name of a ſpecies of marble very hard, and of a beautiful green colour; it is a very cloſe, even, and compact marble; of a fine ſtrong and bright green, and when poliſhed, is the brighteſt of all the green marbles, and is remarkable for this, that the colour is not regularly and equally diffuſed through the whole maſs, but leaves in it many ſpots and lines very bright and pale, and ſome much deeper than the general colour, though

 there

there is no colour but green in the whole, only in different shades and degrees, some parts approaching to black, and others to whiteneſs.

It was originally found only in Egypt, and there not in entire ſtrata, but in large pieces waſhed off from the ſtrata, and ſometimes left on the ſurface, ſometimes buried in the earth, and was greatly valued. It has been ſince found in Italy and Germany, and in England. About five miles from the Hot-Wells at Briſtol there is a ſtratum of it, whence it might be had in conſiderable quantities. Its beauty would ſoon recommend it, if it were once known; and though hard to cut, it would make amends for that by the high poliſh it would take.

LACERNA, a thick coarſe ſort of military garment worn by the ancients.

The *lacerna* was a kind of cloke of woollen, only uſed by the men; who wore it over the toga, and, when that was not on, over the tunica. It was at firſt very ſhort, but growing popular in the Roman army, it was ſoon lengthened.

The *lacerna* was ſcarce known in Rome till the time of the civil wars, and the triumvirate; then indeed it came into faſhion; for the ſoldiers being then frequently in the city, or at the city gates, the ſight became familiar to the citizens, and they fell into the uſe of it; inſomuch that it became the common dreſs of the knights and ſenators, till the time of Valentinian and Theodoſius, when the ſenators were prohibited the wearing of it in the city.

The *lacerna* appears to have been much the ſame with the *chlamys* and *birrus*.

Martial mentions *lacernæ* often ten thouſand ſeſterces price.

LACERTA, *Lizard*, in *Aſtronomy*, a conſtellation of the northern hemiſphere, including, according to Hevelius, ten ſtars, and in the Britiſh Catalogue ſixteen, which are as follow:

Names and ſituations of the ſtars.	Signs.	Longit.		Latitude N.		Magnitudes.
		°	′	°	′	
In the extremity of the tail	♐	19	42	74	24	30	5

LACERTA, the *lizard* or *eft*, in *Zoology*, the name of a large genus of animals, comprehending all thoſe quadrupeds which are oviparous, and have long tails continued from their bodies. The *lizard*, or *lacerta*, in the Linnæan ſyſtem, is a genus of reptiles in the claſs of *amphibia*, diſtinguiſhed by a four-footed naked body, with a tail, comprehending forty-eight ſpecies. The term oviparous is to be underſtood however in a larger ſenſe, expreſſing ſome among theſe, which, though they have true and proper eggs within them, yet never depoſit them as ſuch, but keep them in their bodies till they are hatched, and bring forth living young ones. Some of the ſerpents, as well as ſome of the *lizards*, are of this kind, and the obſervation is as old as Ariſtotle, who calls the creatures, whoſe generation is of this kind, *internally oviparous*, *externally viviparous*. See *Tab. of Serpents*, N° 30, ſeq.

The *lizard* claſs is very numerous; and the ſeveral ſpecies are diſtinguiſhed chiefly by the number of their toes, and the form and length of their tail.

The *lizard* lives in caverns, ruins, and deſolate places. The large green *lizard* is eſteemed above the reſt for medicinal purpoſes; but this being rarely to be found in theſe countries, what we ſay is to be underſtood of the common *lizard*.

Being cut in pieces, or bruiſed, eſpecially the head, and applied with ſalt, it extracts ſplinters, pieces of glaſs, or the like, out of the body. The fleſh, or the aſhes of it, burnt, made into a liniment, with fat, cures an alopecia. It is alſo good againſt the ſting of a ſcorpion, and the bites of other venomous creatures.

LACERTA *anguina*, or *orbicularis*. See EFT.

This ſpecies is found, in the ſpring and ſummer, in moſt ditches and ſhallow ſtanding waters throughout England, but are ſeldom or ever ſeen in winter. Theſe ſmall *lizards* ſhed their ſkins every two or three weeks, and theſe changes may be obſerved by keeping them in a jar of water. The animal begins this work of putting off the old ſkin, by ſoftening it with its fore-feet about the jaws; it then puſhes it backward gently and gradually both above and below the head, till it is able to ſlip out firſt one leg, and then the other; which being done, it proceeds to thruſt the ſkin backwards as far as theſe legs can reach; it is then obliged to rub its body againſt pebbles, gravel, &c. till more than half its body is freed from the ſkin, which appears doubled back, and covering the hinder part of the body and tail. The animal afterwards turning its head round to meet its tail, takes hold of the ſkin with its mouth, and ſetting its feet upon it, by degrees pulls it quite off. The ſkin will be found with its inſide outwards, but not having the leaſt hole or breach. The animal will ſwallow the ſkin whole, as it does its other food, unleſs it be ſpeedily removed. Phil. Tranſ. vol. xliv. p. 532, &c.

LACERTA *chalcidica*, in *Zoology*, the name of a ſpecies of *lizard*, more uſually known by the name SEPS.

LACERTA *orbicularis*, in *Zoology*, the name of a very ſingular ſpecies of *lizard*, which is not long and ſlender like the reſt, but broad and rounded. It is an inhabitant of Mexico.

LACERTA *ſquamoſa*, in *Zoology*, a name given by authors to a ſpecies of *lizard*, more eminently ſcaly than any other kind. The general length of this creature is about a yard and half; his head from the noſe end to the fore-feet, is not above three inches; he has no neck; his trunk from the fore-legs to the hinder, is not above ten inches and a half, but his tail is exceeding long, not meaſuring leſs than a yard and a half quarter; the back part of his head is near two inches over; his noſe about an inch, his body nearly four inches, and his tail very taper; he is all over, except his throat and belly, and the lower part of his fore-legs, and the inward part of the hinder ones, covered with ſcales very thick, and in ſolidity equal to the hardeſt bone; the baſes of the ſcales are of a blackiſh yellow, the reſt of a pale yellow, like that of old ivory; they are ſtriated from the baſe to the cone, and are diſpoſed alternately in the manner of the ſcales of fiſh. It is ſaid to be a very tame and inoffenſive animal.

The throat and belly of this animal are beſet with hairs, and Mr. Ray ſuppoſes it from that, to belong to the viviparous quadrupeds, notwithſtanding that its ſhape has always made it be ranked among the *lizard* kind. It is preſerved in the muſeums of the curious, but we are not acquainted with the part of the world it lives in. Ray's Syn. Quad. p. 275.

LACERTA *ſubterranea*, the *under-ground lizard*, a very diſagreeable and dangerous ſpecies of *lizard*, found in the Antilles-iſlands, and ſome other places. They are often met with by the people who dig in marſhy places, and are of a very formidable aſpect; they are about ſeven inches long. Their back is covered with black gloſſy ſcales, with a few grey ones, mixed here and there among them, and they look ſleek and gloſſy as if rubbed over with oil; the belly is no leſs ſcaly than the back, and their ſkin is of a yellowiſh colour. The head is ſmall and ſharp, and the mouth opens very wide, and is armed with very numerous and ſharp teeth; their eyes are very ſmall. As ſoon as they are dug up, and thrown on the ground, they immediately dig their way in again with their feet, which are prepared for that purpoſe, and armed with ſharp claws; and when they are once in, they burrow their way like moles wherever they pleaſe. They do great miſchiefs to the inhabitants in their gardens and plantation, burrowing horizontally at ſmall depths, and deſtroying the roots of every thing they meet with. Their bite is eſteemed as dangerous as that of the moſt poiſonous ſerpent.

LACERTA *viridis*, the *green-lizard*, a very beautiful creature, which is common in many parts of Italy, and is ſometimes found in Ireland. It is conſiderably larger than our land-eft, and of a very beautiful green. See *Tab. of Serpents*, N° 31.

LACERTA *volans*, is a ſpecies of *lizard*, according to ſome writers, but Linnæus has referred this and another ſpecies to a diſtinct genus, under the name of *draco*; it lives on trees, feeding on ants, flies, and other inſects, and doing no injury to man or any other large animal. It has membranes on its ſides, which ſerve the office of wings, in carrying it from one tree to another, and has been called by Geſner the *dragon* or *winged-ſerpent*.

LACERTUS, in *Ichthyography*, the *lizard-fiſh*, a name given by ſome writers to a fiſh of the cucullus-kind, much reſembling the common mackrel in ſhape and in taſte, and more uſually called trachurus.

LACERTUS is alſo uſed for a fiſh of the garfiſh-kind, or acus *Oppiani*,

Oppiani, but larger than the common species, and called by the Italian fishermen *aguglia imperiale*, or the imperial garfish, and by the fishermen of England, particularly in Cornwall, the *girrock*, in distinction from the common kind which they call *sipper*. It is thicker in proportion to its length than the common garfish, and has a shorter and sharper snout, and instead of teeth, has only its jaws serrated like a file. It is a scarce fish, but is more firm in its flesh than the common garfish.

LACERTUS *alter sphincteris*, in *Anatomy*, a name given by Santorini, and some others, to one of the muscles of the anus, now generally known by the name of the *levator ani*: the *musculus sedem attollens* of Vesalius, and *latus* of others. The thin termination of this muscle, not the whole, is understood by this name.

LACERUM *felinum*, among *Botanists*. See LEAF.

LACHES, (from the French *lascher*, i. e. *laxare*, or *laschè*, *ignavus*) in our law, signifies slackness or negligence; as it appears in Littleton, where *laches* of entry is a neglect in the heir to enter, and probably it may be an old English word; for when we say there is *laches* of entry, it is the same as if it were said, there is lack of entry; and in this signification it is used. Litt. 136. No *laches* shall be adjudged in the heir within the age; and regularly *laches* shall not bar either infants or femes covert for not entry or claim to avoid descents: but *laches* shall be accounted in them, for non-performance of a condition annexed to the state of the land. Co. Litt. 146.

LACHNÆA, in *Botany*, a genus of the *octandria monogynia* class: it has no calyx; the corolla is divided into four segments, with an uneven margin; the seed is single and obliquely acute.

LACHNIS, in *Natural History*, the name of a genus of fossils, of the class of the *fibraria*; the characters of which are, that they are fibrose bodies, not elastic, and composed of short and abrupt fibres, or filaments.

The word is derived from the Greek λαχνος, a hair or short capillament or fibre. See *Tab. of Fossils, Class* 1.

The bodies of this genus are divided into those which are composed of larger and broader, and those which are composed of smaller and narrower filaments. Of the first of these, there are six species known among us; and of the other four.

It is very certain, that most of the rest, from the quantities they are found in, might be made a very profitable thing to the owners of the pits where they lie, though they are in most places neglected.

LACHRYMA *Jobi*, in *Botany*. See JOB's *tears*.

LACHRYMÆ *Batavicæ*. See RUPERT's *drops*.

LACHRYMAL, or LACHRYMAL *gland*, in *Anatomy*, a small oblong gland, situate above the eye, near the little canthus, whence proceed two or three small ducts, which, opening on the inward surface of the eye-lid, filtrate a serosity serving to moisten the ball of the eye, and facilitate its motion.

Near the larger angle is also a little eminence, in form of a caruncle, which some have taken for another *glandula lachrymalis*, but by mistake; this being no more than the duplicature of the inner membrane of the eye-lids. See CARUNCULA *Lachrymalis*.

On the same side near the lesser angle, are two little perforations, called *puncta lacrymalia*.

On the same side is also a small bone, one of those of the upper jaw, sometimes called *os lachrymale*, but more usually *os unguis*.

LACHRYMALIS, *fistula*, is a fistula in the larger angle of the eye.

It usually happens after an abscess formed in the sacculus lachrymalis, by means of the serosity lodged there; which, being retained too long, becomes acrimonious, and occasions an ulcer, which frequently degenerates into a fistula. See FISTULA *Lachrymalis*.

LACHRYMALIS, *saccus*. See SACCULUS and LACHRYMALIA.

LACHRYMALIS, or LACHRYMALIA *puncta*, in *Anatomy*, two little apertures in the great angle of each eye, into which an muco-saline pellucid humour, secreted from the blood by the glandula lachrymalis, is conveyed, and thence carried off by the lachrymal canals, termed *carunculæ*, into a little sac called *saculus lacrymalis*, in the canal of the nose; whence, by a pipe always open, it is carried into the cavity of the nose; immediately under the lower os spongiosum.

Hence appears the reason why people, in crying, run at the nose.

This humour, separated by the glandula lachrymalis, serves to moisten and lubricate the ball of the eye, and prevent any hurtful attrition; when it is secreted in any great quantity, so as to overflow the eye-lids, it is called tears.

LACHRYMATORIES, or LACHRYMATORIES, in *Antiquity*, were small glass or earthen vessels, wherein the tears of the weeping friends that survived were reposited, and buried with the ashes and urns of the dead.

Some of these are still seen in the cabinets of the curious.

LACINIATED *leaf*, in *Botany*. See LEAF.

LACK of *Rupert*. See RUPERT.

LACKER. See LACQUER.

LACMUS. See LITMUS.

LACONIC *style*. See STYLE.

LACONICA *scytala*. See SCYTALA.

LACONISM, *Λακωνισμος*, a short, pithy, sententious speech, in the manner of the Lacedæmonians, who were remarkable for the closeness and conciseness of their way of delivering themselves.

LACQUER or LACKER, is a varnish applied upon tin, brass, and other metals, to preserve them from tarnishing, and to improve their colour. The basis of *lacquers* is a solution of the resinous substance, called seed-lac, in spirit of wine. The spirit ought to be very much dephlegmated in order to dissolve much of the lac. For this purpose, some authors direct dry pot-ash to be thrown into the spirit. This alkali attracts the water, with which it forms a liquid that subsides distinctly from the spirit, at the bottom of the vessel. From this liquid the spirit may be separated by decantation. By this method the spirit is much dephlegmated: but at the same time it becomes impregnated with part of the alkali, which depraves its colour, and communicates a property to the *lacquer* of imbibing moisture from the air. These inconveniences may be prevented by distilling the spirit; or, if the artist has not an opportunity of performing that process, he may cleanse the spirit in a great measure from the alkali, by adding to it some calcined alum, the acid of which uniting with the alkali remaining in the spirit, forms with it a vitriolated tartar, which, not being soluble in spirit of wine, falls to the bottom together with the earth of the decomposed alum. To a pint of the dephlegmated and purified spirit about three ounces of powdered shell-lac are to be added; and the mixture to be digested during some days with a moderate heat. The liquor ought then to be poured off, strained, and cleared by settling. This clear liquor is now fit to receive the required colour, from certain resinous colouring substances, the principal of which are gamboge, and anotto, the former of which gives a yellow, and the latter an orange colour. In order to give a golden colour, two parts of gamboge are added to one of anotto; but these colouring substances may be separately dissolved in the tincture of lac, and the colour required may be adjusted by mixing the two solutions in different proportions.

When silver-leaf, or tin, are to be lacquered, a larger quantity of the colouring materials is requisite than when the *lacquer* is intended to be laid on brass.

There are sundry other materials, from a due mixture of which a like colour may be produced, as turmeric, saffron, dragon's blood, &c. See *Gold Coloured* VARNISH and *Japanner's* GILDING.

Instead of seed-lac, used in the composition of varnishes for *lacquering*, resin or turpentine is substituted for the coarser uses; the following composition for brass-work, designed to resemble gilding, has been much recommended: take of turmeric ground, as it may be had at the dry-salters, one ounce, and of saffron and Spanish anotto each two drams: put them into a bottle with a pint of highly rectified spirit of wine, and place the bottle in a moderate heat, occasionally shaking it, for several days; then strain off the yellow tincture thus obtained, through a coarse linen cloth, and putting it back into the bottle, add three ounces of good seed-lac grossly powdered; place the bottle again in a moderate heat and shake it, till the seed-lac be dissolved. The *lacquer* strained as before will be fit for use and must be kept in a bottle carefully stopped. By increasing or diminishing the proportion of anotto, the *lacquer* will be rendered warmer and redder, or cooler and nearer a true yellow. A cheaper composition, little inferior to the former, may be formed of one ounce of turmeric root ground, half a dram of the best dragon's blood, and a pint of spirit of wine, managed as the former. The varnish for tin may be made of one ounce of turmeric root, two drams of dragon's blood, and one pint of spirit of wine; prepared in the same manner with the other. The dragon's blood may be increased or diminished, as the red or yellow is to be the most prevalent; and for a coarser *lacquer* the quantity of seed-lac may be lessened, and the deficiency supplied by the same proportion of resin. The *lacquer* for locks, nails, &c. where little or no colour is desired, may be either seed-lac varnish alone, or with a little dragon's blood; or a compound varnish of equal parts of seed-lac and resin, with or without the dragon's blood. The manner of laying on the *lacquer* is as follows: the pieces to be Lacquered must first be made thoroughly clean; and if they be new founded, aqua fortis must be used for this purpose. When they are afterwards heated by a small charcoal fire, the *lacquer* is laid on with a proper brush,

like other varnishes, and the pieces restored to the heat. After the *lacquer* is thoroughly dry and firm, the same operation must be renewed four or five times, or till the work appears of the required colour and brightness.

The *lacquering* of leather, improperly called gilding, is performed by means of leaf-silver, coloured by a yellow varnish. See *Japanner's* GILDING. For this purpose calf or goat skins are procured in a dry state, after the common dressing and tanning. They are softened by being immersed and stirred about for some hours in a tub of water; and afterwards beaten against a flat stone and smoothed, by spreading them on the stone and rubbing them over with an iron instrument: the skins, thus prepared, are joined together in pieces of the dimensions required; and then sized on the grain of the leather with a kind of soft glue, or stiff size, that answers to the *gold-size* used in other kinds of GILDING or SILVERING, prepared from parchment or glover's cuttings. The workman next proceeds to cover the whole surface of the sized skin, before it be quite dry, with leaf silver, and with a fox's tail, made into the form of a ball at the end, settles the leaves, by pressing and striking them; and closes this operation with gently rubbing the whole surface with the tail. When the skins are silvered, they are hung to dry first on cords, and the drying is completed by putting them over a board joined together, with the silvered side next the boards, where they must be kept stretched out by means of some nails. They are then burnished with a flint burnisher, which operation is performed by spreading the skin even on a smooth stone and sliding the burnisher backwards and forwards over every part of the skin, with a considerable degree of pressure. In some manufactures the burnishing is performed, by passing the silvered skins betwixt two cylindrical rollers of steel, with polished faces. The skins are now prepared for receiving the yellow *lacquer* or varnish, which gives the appearance of gilding. Different artists have different recipes for compounding this *lacquer*. The following is said to be equal to any hitherto used: take of fine white resin, 4½ pounds; the same quantity of common resin; of gum sandarac, 2½ pounds; and of aloes, two pounds: bruise and mix them; and put them into an earthen pot over a good fire of charcoal, or over any other fire which has no flame: when all the ingredients are perfectly melted and mixed, add gradually to them seven pints of linseed oil, and stir the whole well together with a spatula: let the whole boil, stirring all the time, to prevent a kind of sediment, that will form, from sticking to the bottom of the vessel. When the varnish is almost sufficiently boiled, which will generally require seven or eight hours, add gradually half an ounce of litharge, or half an ounce of red lead; and when this is dissolved, pass the varnish through a linen cloth, or flannel bag. A pint of oil, and a corresponding proportion of fine resin and aloes have produced a very good varnish in an hour and a half. This *lacquer* or varnish is laid on the silvered leather in the open air; and is best done in summer, when it is hot and dry. For this purpose, the skins are stretched and fastened with nails to the boards, on which the drying was finished, with the silvered side outwards. And when these boards are properly disposed on trestels, the workman generally spreads some white of eggs over each skin; and when this is dry, the varnish, which is nearly of the consistence of a thick syrup, is repeatedly spread with the four fingers of one hand, moved to that each finger paints a kind of S with the varnish, from one end of the skin to the other; and it is then diffused evenly over every part with the flat of the hand: after this, it is to be immediately beaten by strokes of the palms of the hands, and principally where the varnish is observed to lie thickest. When this coat of varnish is sufficiently dry, which may be known by the finger's making no impression upon it, another coat is laid on in the same manner. When this coat is dry, the varnishing for producing the appearance of gilding is completed; and if it has been well performed, the leather will have a very fine gold colour, with a considerable degree of polish or brightness. When there is an intention to have one part of the leather silver, and the other gold, a pattern is formed on the surface, by printing, calking or stamping a design on the surface after the silvering. The skin is then to be varnished, as if the whole were intended to be gold; but after the last coat, instead of drying the varnish, it is to be immediately taken off that part, which is intended to be silver, according to the design printed or calked upon it, by a knife; with which the workman scrapes off all that he can without injuring the silver, and afterwards by a linen cloth, with which all that remains is to be wiped or rubbed off. The skins, thus silvered and varnished, are made the ground of various designs for embossed work and painting. The embossed work or relief is raised by means of printing with a rolling press, such as is used for copper-plates; but the design is here to be engraved on wood. The painting may be of any kind; but oil is principally used, as being durable and more easily performed. Dossie's Handmaid to the Arts, vol. i. p. 454, &c.

LACRYMA *cervina*, in *Natural History*, a little round and hard bone, said to grow in the great corner of a stag's eye after a certain age. Some also preserve under this name a thickened excretion from the inner angle of that creature's eye, in colour and consistence resembling myrrh, or ear-wax, long hardened in the ear. This is of a strong and very disagreeable smell, like the sweat of the same animal, and is all med to be sudorific and alexipharmic.

LACRYMÆ *Christi*, the name of a sort of wine produced by grapes on the lower part of Mount Vesuvius; so called from the drops of juice oozing from the grapes, when fully ripe.

LACRYMAL. See LACHRYMAL.

LACTARIA, in *Botany*. See MILK-*wort*.

LACTARY *Column*. See COLUMN.

LACTATION, the act of giving suck.

The word is also applied to the time during which the mother doth that office to her young.

LACTEA *via*, the milky way. See GALAXY.

LACTEALS, or LACTEAL *veins*, or *vessels*, a kind of long slender tubes, for the conveyance of the chyle from the intestines to the common reservatory.

They are called veins, because their valves are disposed as those of the ordinary blood-veins, and because the fluid which they contain runs from smaller into larger tubes.

They appear to have been known to Hippocrates, Erasistratus, and Galen; but were first duly described and published by Aselius, an Italian physician, in 1627, and called *lacteals*, from the liquor they contain, which resembles milk. Vid Doug. Bibl. Anat. p. 296. ed. 1734.

Their coats are so thin as to be invisible, except when distended with chyle, or lympha. They arise from all the parts of the small guts, and as they run from the sides of the guts to the glands in the mesentery, unite, and form larger branches, called *tunæ lacteæ primi generis*. The mouths of these *lacteals*, which are open into the cavity of the guts, from whence they receive the chyle, are so small, as not to be seen by the best microscope. It was necessary they should be smaller than the finest arteries in the body, that nothing might enter to stop the circulation of the blood.

The same extremity of the *lacteals* has likewise a communication with the capillary arteries of the guts, by which they receive a lympha that dilutes, and propels the chyle forwards, and washes the *lacteals* and glands, that they might not fur, and be obstructed by the chyle's staying in them upon settling.

The other extremity of the *lacteals* discharges the chyle into the velicular cells of the glands dispersed up and down the mesentery; and from these arise other *lacteals*, of a larger size, which carry the chyle immediately into the receptaculum chyli, and these are called *lacteæ secundi generis*.

The *lacteal veins* have valves at proper distances, which hinder the chyle from returning back into the intestines. Winslow has divided the *lacteal* vessels in the human body into three clules: they derive, he says, their first origin from the tunica vellosa of the intestines, and chiefly from that of the small intestines, by a great number of small capillary roots. From these roots there arises, between the coats of the intestines, a kind of reticulum mirabile, which surrounds almost the whole circumference of the intestinal canal, between the muscular and external coat: this reticular texture of lacteal vessels keeps close to the external coat, and leaves the canal along with it, on the side of the mesentery, where it forms two planes of ramifications, plainly distinguished from each other by the cellular substance, and adhering close to the inside of the two membranes of the mesentery. In this separate state they run up the lamina of the mesentery as far as the first mesenteric glands, where [illegible] into one plane. These Winslow re[illegible] the first class of *lacteals*. The se[illegible] class includes those vessels, which, after this uni[illegible] distributed almost uniformly through the whole e[illegible] the mesentery, from its circumference to its origin or adhesion to the vertebræ of the back, between the mesenteric glands, forming frequent anastomoses or communi[illegible]. The third class includes those ramifications, which, after having passed through the mesentery, begin to unite as they approach the spina dorsi to that their number is lessened and their size increased; and having passed the last mesenteric glands, terminate about the middle of the adhesion of the mesocolon in small common trunks, which receive a great number of lymphatic vessels from the

the glandulæ lumbares, and others below these. The *lacteals* of this last class run down on the body of the inferior aorta, between the extremities of the small muscle of the diaphragm, and terminate in a kind of cistern, called RECEPTACULUM *chyli*.

It has been doubted, whether or no the intestina crassa have any *lacteals* or not. The impossibility of human dissection proper for such an enquiry, gives no room either to affirm or deny. But the contents of the thick intestines seem not likely to afford much chyle; and therefore, if there be any *lacteals*, it is probable they are very few.

However Winslow informs us, that he has exhibited several of these, very full of chyle, to the Royal Academy, in a human colon. And of these he makes a fourth class. The *lacteal* vessels, in general, may be seen in those who die a violent or sudden death, soon after a meal; and they remain visible even in the intestines, for a long time after death, when a great number of the mesenteric glands have become schirrous, especially in children. Anat. vol. ii. § 8 N° 215, &c.

In brutes, if dissected at a reasonable time after feeding, as two or three hours, the *lacteals* appear very turnid and white; and, if wounded, the chyle flows plentifully from them. But if inspected when the stomach of the animal has lain some time empty, they appear like lymphatics, visible indeed, but filled with a transparent liquor.

That the *lacteals* have a communication with the cavities of the intestines, is evidently demonstrated by their contents, the chyle; but how their pores are disposed to receive it, has not yet been discovered; nor is there any way known whereby to fill the *lacteals* from the cavities of the guts after death. It is probable then, their entrance into the gut is oblique, since neither wind nor liquors can pass from thence. As it is found these pores can only receive any thing in their living state, we may be allowed to imagine, that it is the peristaltic motion of the guts which disposes them in that state to receive the chyle. And this may be done by means of the circular and longitudinal fibres of the intestines still applying the internal coats of the guts to their contents, by which means its pores absorb the chyle from the excrementitious part.

The *lacteals* are the absorbents of the bowels, beginning in their inner surface: the same kind of vessels are called absorbents in other parts of the body, and take their rise from the surfaces of the respective parts; so that the *lacteals*, LYMPHATICS, and ABSORBENTS, are the same kind of vessels. Some anatomists have considered the *lacteals* and lymphatics as the same vessels, differing only in their situation, and both terminating in the same duct.

The ingenious Mr. Hewson discovered the lymphatic system in birds, fish, and turtle, and an account of his discovery was published in the Phil. Trans. vol. lxii. art. 34. p. 217, and vol. lix. art. 28. p. 198. and art. 29. p. 204. However, these discoveries were claimed by professor Monro in a letter read before the Royal Society in 1769, and the claim was afterwards supported in a pamphlet, called, A state of facts, &c. printed at Edinburgh in 1770. The professor alledges, that he injected the *lacteals* of a sea-tortoise or turtle with quicksilver, after injecting every artery and vein with wax, in the year 1765; and that as early as the year 1761, he had mentioned the *lacteal* vessels in fowls and fishes, though he had not injected them. Mr. Hewson replies, that the professor's not having injected the *lacteals* in fowls and fishes afforded a strong presumption that he had not discovered them; more especially as in a work printed in 1758 he had declared, that, after a considerable number of experiments, he was convinced that neither birds, fish, nor amphibious animals in general, had either *lacteals* or lymphatics: because, after having seen these vessels, he would naturally have endeavoured to inject them. He also alleges, that the professor publicly declared in his lectures since the year 1762, that he had sought for the *lacteals* in fowls and fishes in vain by a variety of experiments; and so late as the year 1767, he also declared that the lymphatic system was supposed to take place in men and viviparous animals, and, by analogy, in those kinds which Linnæus has classed among the mammalia. Adding, that he had found the *lacteals* in some amphibious animals, as the turtles. Upon the whole, the dispute between Mr. Hewson and the professor seems to be reduced to this single point, which of them first discovered the *lacteals* of birds; both agreeing that the lymphatics in their necks had been discovered by Mr. Hunter many years before: and Mr. Hewson acknowledges, that the *lacteals* of the turtle were discovered by the professor in 1765, some years before the publication of his own paper in the Philosophical Transactions; though he says, that the description of those vessels, published in that paper, was taken in 1763. It seems also to be agreed, that the professor had seen what he suspected to be *lacteals*; but Mr. Hewson insists that he had not discovered them before him. For a farther account of the state of this controversy, the reader may consult Monro's pamphlet above mentioned, and Mr. Hewson's Appendix to his Experimental Inquiry into the Properties of the Blood, &c.

LACTEAL *fevers*, a term used by *Medical Writers* to express what the women call *milk-fevers*, that is, such fevers as attend the difficult ingress of milk to the breasts of lying-in women.

LACTEUS *lapis*, in *Natural History*, a name given by some authors to the *galactites*.

LACTIFERI *tubuli*. See TUBULI.

LACTIFEROUS, an epithet applied to such plants as abound with a milk-like juice, such as the tithymal, sow-thistle, and many others.

LACTUCA, in *Botany*. See LETTUCE.

LACTUCA *marina*, *sea-lettuce*, in *Botany*, a name used by some authors for the *lichen marinus*, commonly called *sister-green*.

LACUNÆ, among *Anatomists*, certain excretory canals in the genital parts of women. See *Tab. Anat. (Splanch.) Fig.* II. *lit* II.

Between the fleshy fibres of the ureters, and the membrane of the vagina, is found a whitish glandulous body, about a finger thick, running round the neck of the bladder, having a great number of excretory ducts, which de Graef calls *lacunæ*, and which terminate in the lower part of the orifice of the womb; conveying thither a slimy matter, that mixes with the semen of the male.

LACUNAR, in *Architecture*, an arched roof, or ceiling more especially the planking or flooring over porticoes or piazzas.

LADA, in *Botany*, a name given by some authors to the plant which produces the common black pepper.

LADANUM, or LABDANUM, in *Pharmacy*, a gummous or a resinous matter, oozing out of the leaves of a shrub called *cistus ladaniferus*, which is very common in the hot countries of the Levant, and whereof there are various kinds. The shrub is also plentiful in Spain, though no *ladanum* is brought from thence.

Dioscorides says, they gather the *ladanum* by means of goats, which, brousing on the leaves of this shrub, return to the stable with their beards loaded with a fat substance, which the peasants rake off, with a kind of combs made for that purpose. This matter they thus collect into lumps, and, as it is mixed with the goats hair, and other impurities, call it *ladanum in the beard*, or *natural ladanum*. Others are said to draw cords over the leaves, and other parts of the shrub; and, scraping off what had stuck to the cords, they make up the *ladanum* into little balls.

Tournefort assures us, that the common way of gathering the *ladanum* at this time is, by brushing it off the leaves with a sort of whip, composed of many lashes, or straps: after it is scraped off the straps, they make it into cakes of different sizes.

Pietro delle Valle tells us, he was informed by the Indians, that *ladanum* is formed like dew, and falls from heaven like manna; that it is gathered on the leaves of a plant a palm and an half high; that, after gathering, they boil it, by which means it becomes soft, like wax.

Belloulus says, that this juice is collected by lightly brushing the shrub, in the summer heats, with a kind of rake, having several straps or throngs of leather fixed to it, instead of teeth; the unctuous juice adheres to the throngs, and is afterwards scraped off with knives.

There are two sorts of *ladanum* in the shops: the best, which is very rare, is in dark coloured masses, of the consistence of a soft plaster, which becomes still softer on being handled. The other is in long rolls coiled up, and much harder than the preceding and not so dark. The first has commonly a small, and the last a very large admixture of fine sand, blown upon the juice from the sandy soil where it is found.

Ladanum has been sometimes exhibited as a resinous corroborant and restringent, but it is principally employed in external applications and perfumes. The soft kind, which has an agreeable smell and a lightly pungent bitterish taste, makes an useful ingredient in the cephalic and stomachic plasters of the shops. Rectified spirit of wine dissolves nearly the whole of the pure *ladanum* into a gold-coloured liquor. Water acquires by infusion much of its smell and taste: and, by distillation in water an essential oil arises, leaving a brittle almost insipid resin and a pale-coloured liquor, which, inspissated, yields a weakly bitterish extract. Heat soon destroys the specific flavour of this juice. Lewis.

LADANUM, *Liquid* more properly called *clear*, or *purified ladanum*, is a preparation of the natural *ladanum*, by melting and purifying it from the hairs, &c.

This hardened is sometimes sold for a sort of black ambergris.

LADDER *to heaven*, in *Botany*. See LILY *of the Valley*.

LADDERS, *scaling*, in the *Military Art*, are used in ESCALADE. They are of various sorts; some are of ropes and some of wood; some are made of several joints, so as to be capable of being put together, and to form *ladders* of different length, according to the service required. There is a sort used in England, much of the same make as the common *ladders*, except that the steps turn about wooden pegs, so that the poles may be brought near each other, or to shut like a parallel ruler. These are very convenient for carriage.

LADDERS, in a *Ship*, derive their names from the several hatchways or other parts where they are situated. Besides these, there are some of a particular construction, as the accommodation-*ladder*, and the quarter-*ladder*. The *accommodation-ladder* is a sort of light stair-case, occasionally fixed on the gang-way of the admiral, or commander in chief of a fleet. It is furnished with rails and entering ropes, covered with red bays, and the lower end of it is kept at a proper distance from the ship's side by iron-bars or braces, to render the passage more convenient to those who enter or leave the ship. *Quarter-ladders*, are two ladders of rope, depending from the right and left side of the ship's stern, whereby to descend into the boats which are moored astern, in order to bring them up along-side of the ship, or to use them for any other occasion.

LADEN, in *Sea Language*, denotes the state of a ship when she is charged with a weight or quantity of any sort of merchandize or other materials, equal to her tonnage or burthen. If the cargo, with which she is *laden*, be extremely heavy, her burthen is denominated by the weight of the goods; if it be light, she carries as much as she can stow, so as to be fit for the purposes of navigation. A ton in measure is generally estimated at 2000 lb. in weight, and therefore a vessel of 200 tons ought to carry a weight of 400,000 lb. when the matter of which the cargo is composed is specifically heavier than the water in which she floats.

LADEN, in *Bulk*, denotes the state of being freighted with a cargo, which is not in casks, boxes, bales, or cases: but lies loose in the hold, being defended from the moisture or wet of the hold, by a number of mats and a quantity of dunnage. Such are usually the cargoes of corn, salt, or such materials.

LADING. See BILL *of Lading*.

LADLE *of a gun*, the instrument wherewith the powder is put into the piece.

It is made of a plate of copper bowed in form of a half-cylinder, rounded at one end, the other being fixed upon a long staff; this filled with powder, the gunner carries, with his left hand under the end of it, to keep the powder from falling out, till he enters it in the muzzle of the piece; when he has carried the powder home to the charged cylinder, he turns the *ladle*, that the powder may fall out, and withdraws it.

Ladles are fitted to the bore of each gun, and hold powder sufficient for the charge.

Small *ladles*, with short handles of wood, are also used in filling the fuzes of shells, or any other composition for filling the cases of rockets, &c.

LADLE-*boards*, those boards disposed on the circumference of the water-wheels of over-shot mills; forming hollows, or receptacles, not unlike *ladles* to receive the water that falls upon the wheel. See *Water*-WHEEL.

LADONIS, in the *Materia Medica of the Ancients*, a name given by some to the laurus or bay-tree. We find the word in a composition prescribed in Galen, from the works of some of the empirics of his time, but it never was used by the more regular authors.

LADRE, in the *Manege*, denotes *Dull*. See HORSE.

LADY's *bed-straw*, or *cheese-rennet*, *gallium*, in *Botany*, a genus of the *tetrandria monogynia* class. Its characters are these: the flower which hath an empalement, indented in four parts, has also one petal, divided into four parts, and also four awl-shaped stamina: it has a twin germen situated under the flower, which afterwards become two dry berries, joined together, each including a large kidney-shaped seed. There are several species, of which, the sort commonly used in medicine is very common in moist meadows and pasture grounds, and flowers in June and July.

This plant is drying and incrassating, good in stopping all kinds of fluxes and hæmorrhages, and for the cure of wounds: some commend a decoction of it for the gout; and a bath made of it is refreshing to wash the feet of persons tired with over walking. In the northern countries they use this herb for the making cheese, instead of rennet, whence it is called *cheese-rennet*; the flowers containing an acidity, which may be extracted by distillation. This plant is but seldom used in the shops.

LADY's *bower*, in *Botany*. See VIRGIN's *Bower*.

LADY-*bird*, in *Zoology*. See HEMISPHERIA and SCARABÆUS.

LADY's *comb*, in *Botany*. See SHEPHERD's *needle*.

LADY's *cushion*, in *Botany*. See SAXIFRAGE.

LADY-*day*, in *Law*, the twenty-fifth of March, being the ANNUNCIATION of the holy Virgin.

LADY's *finger*, *anthyllis*, in *Botany*, a genus of the *diadelphia decandria* class. Its characters are these: the flower is of the butterfly kind, having a long standard reflexed on both sides beyond the empalement; the two wings are short; the keel of the same length and compressed: in the centre is situated an oblong germen, which becomes a small roundish pod inclosed by the empalement, having one or two seeds. There are several species.

LADY's *Mantle*, *alchemilla*, in *Botany*, a genus of the *tetrandria monogynia* class. Its characters are these: the flower has a permanent empalement of one leaf, which is cut into eight segments; it has no petals, and each flower is succeeded by one seed wrapped up in the empalement. Miller reckons four, and Linnæus three species. The common sort, used in medicine, grows naturally in dry fields and meadows in several parts of England; but is not very plentiful near London; and flowers from May to August.

The leaves are used, and are esteemed to be vulnerary, drying, and binding, and of great force to stop inward bleedings.

Their styptic matter is extracted both by water and spirit: the roots are more astringent than the leaves; and the extracts made from them proportionably stronger.

LADY's *seal*, in *Botany*. See TAMUS.

LADY's *slipper*, *cypripedium*, in *Botany*, a genus of the *gynandria diandria* class. Its characters are these: it has a simple spadix; the germen sits under the flower, which is covered with a sheath; the flower has four or five narrow spear-shaped petals which expand; the nectarium which is situated between the petals, is swollen and hollow, in shape of a shoe or slipper; and it has two short stamina; below the flower is fixed a slender contorted germen; which becomes an oval blunt capsule with three corners, having three valves and one cell, filled with small seeds. There are two species.

LADY's *smock*, in *Botany*. See CARDAMINE.

LADY's *traces*, in *Botany*. See TWYBLADE.

LADY *of the Thistle*. See THISTLE.

LADY, *Presentation of our*. See PRESENTATION.

LÆNA, among the *Ancients*, a thick shaggy upper garment. See CHLÆNA.

LAERTA, in *Natural History*, a name given by authors to a species of vespa or wasp, whose sting is said to be fatal: but this is an erroneous opinion. This wasp is larger and longer bodied than the common kind, but smaller than the hornet. It seems of a very irritable disposition, attacking animals of any kind that come in its way.

LAETIA, in *Botany*, a genus of the *polyandria monogynia* class: the corolla has five petals; the calyx is composed of five leaves; the fruit is three-lobed and contains a single cell; the seeds are inclosed in a pulpy coat.

LAFORDSWICK, (Saxon, *blafred*, i. e. *dominus*, and *wic*, *præditio*, *infidelitas erga dominum*) the betraying of a lord or master. This word is found in king Canute's laws, c. 61. and in the laws of king Henry I.

LAGA, in *Antiquity*, denotes *lex* or *law*: whence are deduced *Saxon-lage*, *Danelage*, &c.

LAGAN, or LAGON, in our *ancient Sea Laws*, shipwrecked goods, left by the sea, lying on the sand, either ashore, or out at sea.

The word seems formed from the Saxon *legan*, or *lagan*, *jacere*, *to lie*. Though others deduce it from the Latin *ligare*, *to bind*; and suppose it to denote goods tied together with a buoy, or the like, to hinder their sinking to the bottom, that they may be found again.

Lagan is usually joined with jetson and flotson.

LAGANUM, in *Natural History*, the name of a genus of the *echini marini*, of the general class of the echinus. The characters of the *lagana* are, that they have their mouth in the center of the base, and their aperture for the anus in its third region; that their substance is whole, and their edges waved. Of this genus there are five known species.

LAGEMAN, *(lagamannus) homo habens legem, or legalis seu legitimus*: such as we call now good men of the jury. The word is frequently used in Domesday, and the laws of Edward the Confessor, cap. 38.

LAGEN, *lagena*, in ancient time, was a measure of wine, containing six sextarii: whence probably is derived our *flagon*. The lieutenant of the Tower has the privilege to take *unam lagenam vini ante malum & retro*, of all wine ships that come up the Thames; and sir Peter Leicester, in his Antiquities of Cheshire, interprets *lagena vini*, a bottle of wine.

LAGERSTROEMIA, in *Botany*, a genus of the *polyandria monogynia* class: the corolla is curled, and has six petals; the calyx is campanulated and divided into six segments:

the ſtamina are numerous, the outer ſix being thicker and longer than the petals.

LAGINE, in *Natural Hiſtory*, a name given by Pliny to a climbing-plant, of the nature of that from which ſcammony was obtained, but ſmaller, and thence called by ſome *ſcammonea parva*, the ſmaller ſcammony. The ancient Greeks have called this plant *ſaſine*; and it appears very probable, that the word *lagine* here mentioned by Pliny is but a corruption of that name.

LAGOCEPHALUS, in *Zoology*, the name of a ſpecies of orbis or globe-fiſh. It is about a foot long, and half a foot high.

LAGOECIA, in *Botany*. See *Baſtard* CUMIN.

LAGOPHTHALMIA, derived from λαγὼς, *hare*, and ὀφθαλμὸς, *eye*: this being the property of the eyes of hares: λαγοφθαλμία, a diſeaſe of the eye-lids, when the upper lid is ſo contracted, that the eye cannot be quite ſhut, but remains open even in the time of ſleep.

LAGOPUS, in *Ornithology*. See PTARMIGAN.

LAGOPUS is alſo the name of a ſpecies of the CANIS with a ſtrait tail thoughout of the ſame colour. It is ſometimes called the white fox, the iſatis, and the ſky-coloured fox. It is found in Lapland and Siberia.

LAGOUDI, a name given by the Indians to a tree, which produces the leſſer GALANGAL-root of the ſhops.

LAGRIMOSO, in the *Italian Muſic*, is uſed to ſignify a plaintive manner of ſinging or playing.

LAGURUS, *hare's tail graſs*, in *Botany*. See GRASS.

LAICA *vi removenda*. See VI.

LAID-*up* is applied to a ſhip, when ſhe is either moored in a harbour during the winter ſeaſon, or laid by for want of employment; or when ſhe is become incapable of farther ſervice.

LAID *under metal*. See METAL.

LAIR, or LAYER, in *Gardening*. See LAYER.

LAIR, LAYR, or LAYER, among *Sportſmen*, denotes a place where deer harbour by day.

LAIR, or LAYR *of a deer*, is the impreſſion which the beaſt has made on the graſs and ground, where he has lain down, or repoſed.

LAIR, among *Huſbandmen*, alſo denotes a place where cattle uſually reſt, under ſome ſhelter; the ground being enriched by their dung.

LAITY comprehends ſuch of the people as are not included under the denomination of CLERGY; and may be divided into three diſtinct ſtates, viz. the CIVIL, the MILITARY, and the MARITIME.

LAKE, a collection of water, incloſed in the cavity of ſome inland place, of a conſiderable extent and depth.

According to ſome authors, thoſe only are properly called *Lakes*, which receive and emit rivers.

Lakes, however, may be divided into four kinds: 1. Such as neither receive nor emit rivers. 2. Such as emit rivers, without receiving any. 3. Such as receive, without emitting any. 4. Such as both receive and emit rivers.

Of the firſt kind, ſome are perennial, others temporary: the temporary owe their origin, moſt of them, to rain, and to the cavity or depreſſion of the place where they are lodged.

In the Indies they make artificial *lakes*, of a mile or two in compaſs, which they wall about to catch the rain in wet ſeaſons, and preſerve it for their uſe in the dry ones. There are ſeveral of this kind of *lakes*, formed alſo by the inundations of the ſea and rivers, particularly the Nile and Niger; which, when they retire within their banks, leave floods of water, which the inhabitants take care to incloſe, to ſerve as a magazine for the enſuing months. There are ſeveral of theſe *lakes* alſo in Muſcovy, Finland, and Lapland, generated partly by the rain, and partly by the melting of the ice and ſnow.

The generation of perennial *lakes* may be alſo referred to rain, where the cavity is ſo deep as to receive a quantity in winter, more than the heat of the ſun will be able to exhale in ſummer; though it is probable many of theſe *lakes* have their ſprings at bottom, by which they are alſo continually ſupplied.

The only large *lake* of this ſort is the *lake* of Parime in America, lying directly under the equator, which is, in length, about three hundred and five German miles, and at the greateſt breadth about one hundred miles. To this claſs may be referred the turloughs, i. e. *terreus lacus*, or land-*lakes*, in Ireland, which are *lakes* one part of the year, and the reſt ſmooth fields: at the bottom of theſe turloughs are found holes, through which the water ſprings in winter, and ſinks towards ſummer.

The ſecond ſpecies of *lakes*, which emit, without receiving rivers, is very numerous; they owe their origin to ſprings, the cavities where the ſpring is found not being able to contain all the waters it yields. See SPRING. Of this kind is the Wolga, at the head of the river Wolga; the *lake* Odium, at the head of the Tanais; the Adac, whence flows one of the branches of the Tigris, the Ozero or White *Lake* in Muſcovy, that gives ſource to the river Shackſna; the *lake* Chaamay, to the eaſtward of the river Ganges, whence flow four very large rivers, the *lake* Nicaragua, in America; the *lakes* Frontena in Canada, out of which iſſues the river St. Lawrence, &c. The third kind, viz. thoſe which receive rivers without emitting any, apparently owe their origin to thoſe rivers, which, in their progreſs from their ſource, falling into ſome ample cavity, are collected together, and form a *lake* of ſuch dimenſions, as may loſe as much by exhalation as it continually receives from its ſprings; or to a river's flowing on a ſoft ſpongy ſoil, which imbibes the water, and tranſmits it to the neighbouring grounds. The number of theſe is but ſmall.

The *lake* Aſphaltites, called the Dead Sea, is of this kind, receiving the river Jordan, but emitting none; the *lake* of Geneva, the lake Soran in Muſcovy, &c.

Of the fourth ſpecies, which both receive and emit rivers, we reckon three kinds; as the quantity of water they emit is greater, equal, or leſs than that they receive. If the quantity they emit be greater, it is plain they muſt have a ſpring at the bottom; if leſs, there muſt be ſome ſubterraneous ducts, or canals, or elſe the earth muſt be ſpongy; if it be equal, we gather, that they have neither any hidden ſprings nor canals. Of theſe *lakes* we have a great number, and thoſe very conſiderable ones.

The generality of *lakes* conſiſt of freſh waters, as moſt of thoſe which are ſupplied either from ſome ſpring, far from the ſea, or a river, or from the rain: ſome few of ſalt water, as thoſe produced from the inundation of the ſea, or by its immiſſion through ſome duct of the earth, or that have ſalt ſprings at bottom.

Dr. Halley is of opinion, that all great perennial *lakes* are ſaline, either in a greater or leſs degree; and that this ſaltneſs increaſes with time; and on this foundation, he propoſes a method for determining the age of the world.

The large *lakes*, wherewith the northern regions abound, ſerve for very good purpoſes, inaſmuch as the warm vapours ariſing from them ſerve for a defenſative againſt the pinching cold of thoſe climates. To this it is owing, that Ireland, Scotland, &c. are leſs affected with froſts than much warmer countries.

They alſo furniſh exhalations and vapours, which diſtil on the countries bordering upon them in refreſhing ſhowers, and prevent their being barren deſerts.

The *lake* Neſs in Scotland has been commemorated by many writers, but never with any degree of judgment, till Mr. Fraſer gave a perfect account of it to our Royal Society. It never freezes though the winters be ever ſo ſevere, and is full of ſprings in almoſt every part; and its waters, in the time of the ſevereſt froſts, run fluid, and ſmoaking, for ſix miles down the river into which they are diſcharged, while every thing is frozen about them. The river runs very ſlowly notwithſtanding, and from this ſmoak of the water there is raiſed a ſort of fog which overſpreads the whole country for ſeveral miles. There is a mountain near its ſide, of two miles perpendicular height from the ſurface of the *lake*; and on the ſummit of this mountain there is another *lake*, which has no ſpring viſibly running into it, nor any outlet, and yet always keeps of the ſame degree of fulneſs, ſummer and winter. Due weſt from the river into which the lower *lake* diſcharges itſelf, there is an opening of ſea, or frith, of two miles long and ſix miles wide; the middle of this is ſometimes dry, and it is then eaſily ſeen that this was once dry land, and an inhabited country. There are found there large bodies of trees felled, and lying ſtraight along: The wood of theſe is black but it is very ſound, and there are many tumuli, or heaps of ſtones, to be ſeen under water in different parts of the frith, one of which is acceſſible at low water, and there have been found in it urns, which prove that they have been all burying-places. Phil. Tranſ. N° 253. p. 231.

As the ſea waſhes away the banks of this frith, there is found in many places a large quantity of wrought timber; beams of fourteen, or more feet long, with the marks of the axe and other inſtruments upon them; and at the depth of ſixteen feet, in the ſteep banks of the neighbouring river Beuly, there are found oak-trees and pieces of burnt timber. We find by this, that the face of the whole country hereabout is very different from what it was ſome ages ago; and there ſeems ſome reſemblance between the preſent face of things here, and that in the bogs of many parts of England. The trees found buried in theſe were felled by the conquering Romans, and perhaps theſe are of ſome ſuch origin.

We have many ſingularities offering to our view in the *lakes* of our own country; that of their freezing at peculiar ſeaſons is not one of the leaſt. Philoſophical Tranſ. N° 114.

The ſtrange effect of ſome *lakes*, on their water being diſturbed, are recorded by many writers with an air of truth; but are to be examined with great caution, before they

they are credited. Wagner, in his Hiſtory of Switzerland, quotes no leſs than thirty-five authors, who ſay, that a water there called the *Lake of Pilate*, is of this kind, and that it cauſes tempeſts, rain, thunder, *&c.* if any thing be caſt into it; but the truth is, that it is a very tame puddle, ſcarce deſerving the name of a *lake*; and it is proved, by experience, that no conſequence at all attends the throwing it into confuſion by any means whatever.

LAKES, *ſubterranean*. That there are in many places immenſe *ſubterranean lakes*, can ſcarce be doubted, becauſe we ſee them in ſome places; but their effects are often perceived where they are not ſeen, and puzzle the people who attempt to account for thoſe effects upon other principles. The famous Zirchnitzer *lake* in Carniola, which fills and empties itſelf, at times, in an impetuous manner, bringing up with its waters fiſh, and even wild fowl, communicates with another immenſe *ſubterranean lake* in the mountain Savornick; and according to its filling or emptying, the upper one is alſo filled and emptied. See DUCK.

The grotto Podſperſchio, in the ſame country, gives another inſtance of ſuch a *ſubterranean lake*. The people of the neighbouring country enter the ſide of the mountain where this *lake* is, by a ſmall opening, through which they go to a cavern of a great width and height; and at the end of this is a ſmall opening again, through which they go on to the edge of a vaſt ſubterranean piece of water. They go with torches, and find the water very clear and fine. If is ten cubits deep at the edge, and doubtleſs is much more in the middle. The water runs into this *lake* by a large channel, and runs out of it again by another, falling down a precipice into another *lake*, and that with ſuch a noiſe, that the report of a piſtol cannot be heard near it. Stones thrown in every way are heard to fall into water, and there is great reaſon to ſuppoſe the *lake* a German mile long; for at that diſtance there is another water diſcovered through ſuch another cleft of the rock, which ſtands at the ſame horizontal height as this, and is ſubject to the ſame accidents at the ſame times. This vaſt body of water ſometimes all runs off in a few minutes, and leaves the baſon dry, and after ſome weeks it fills again with a frightful noiſe. As theſe accidents always happen to both the waters above mentioned at the ſame time, they appear very plainly to be only the two ſides of the ſame *lake*. Phil. Tranſ. N° 191. We have in England many of theſe reſervoirs, the water of which is always remarkably clear and cold, and is ſo loaded with ſpar, that it generally incruſts things very quickly that are put into it; and when raiſed into vapours, as a part of it ſometimes is, by the ſubterranean heat, or carried up with other vapours, ſtops at the cieling of the vaults, and there forms ſtalactitæ, and other ſuch concretions. In many of theſe *lakes* alſo are found the round balls of ſpar, called *ſtalagmitæ*. They are compoſed of ſeveral cruſts gathering round ſome central nucleus, and often exceed the ſize of a ſchool-boy's marble. Phil. Tranſ. N° 144.

In Pen-Park hole, in Glouceſterſhire, there is a remarkable inſtance of this, that ſtrange cavern containing one of the largeſt of the *lakes* in our kingdom.

It was accidentally diſcovered by ſome miners: it is twenty-nine fathoms deep from the ſurface, being a vaſt cavern of the ſhape of a horſe-ſhoe, ſurrounded with rugged rocks and rough walls of earth, containing in the midſt of it a river or ſubterranean *lake*, twenty fathom broad and eight fathom deep, of the ſame cold and petrifying water with the other reſervoirs of this kind.

LAKE, or LAQUE, a preparation of different ſubſtances into a kind of magiſtery for the uſe of painters. One of the fineſt and firſt invented of which, was that of *gum-lacca* or *lacque*; from which all the reſt, as made by the ſame proceſs, are called by the common name *laques*. See LACCA.

The method of preparing theſe, in general, may be known by the example of that of the curcuma-root of the ſhops, called *turmeric-root*; the proceſs for the making of which is this: take a pound of turmeric-root in fine powder, three pints of water, and an ounce of ſalt of tartar; put all into a glazed earthen veſſel, and let them boil together over a clear gentle fire, till the water appears highly impregnated with the root, and will ſtain a paper to a beautiful yellow. Filtre this liquor, and gradually add to it a ſtrong ſolution of roch-alum in water, till the yellow matter is all curdled together, and precipitated; then pour the whole into a filtre of paper, and the water will run off and leave the yellow matter behind. It is to be waſhed many times with freſh water, till the water comes off inſipid, and then is obtained the beautiful yellow, called *lake of turmeric*, and uſed in painting.

In this manner may a *lake* be made of any of the tinging ſubſtances that are of a ſomewhat ſtrong texture, as madder, logwood, *&c.* but it will not ſucceed in the more tender ſpecies, as the flowers of roſes, violets, *&c.* as it deſtroys the nice arrangement of parts in thoſe ſubjects, on which the colour depends.

A yellow *lake* for painting is to be made from broom-flowers in the following manner: make a lee of pot-aſhes and lime reaſonably ſtrong; in this boil, at a gentle fire, freſh broom-flowers till they are white, the lee having extracted all their colour; then take out the flowers, and put the lee to boil in earthen veſſels over the fire; add as much alum as the liquor will diſſolve; then empty this lee into a veſſel of clean water, and it will give a yellow colour at the bottom. Let all ſettle, and decant off the clear liquor. Waſh this powder, which is found at the bottom, with more water, till all the ſalts of the lee are waſhed off; then ſeparate the yellow matter and dry it in the ſhade. It proves a very valuable yellow.

Lake is at preſent ſeldom prepared from any other ſubſtance than ſcarlet rags, cochineal and Braſil wood. The beſt of what is commonly ſold is made from the colour extracted from ſcarlet rags, and depoſited on the cuttle-bone; and this may be prepared in the following manner: diſſolve a pound of the beſt pearl-aſhes in two quarts of water, and filter the liquor through paper; add to this ſolution two more quarts of water and a pound of clean ſcarlet ſhreds, and boil them in a pewter boiler, till the ſhreds have loſt their ſcarlet colour; take out the ſhreds and preſs them, and put the coloured water yielded by them to the other: in the ſame ſolution boil another pound of the ſhreds, proceeding in the ſame manner; and likewiſe a third and fourth pound. Whilſt this is doing, diſſolve a pound and a half of cuttle-fiſh bone, in a pound of ſtrong aqua fortis, in a glaſs receiver; adding more of the bone, if it appear to produce any ebullition in the aqua fortis; and pour this ſtrained ſolution gradually into the other; but if any ebullition be occaſioned, more of the cuttle-fiſh bone muſt be diſſolved as before, and added, till no ebullition appears in the mixture. The crimſon ſediment depoſited by the liquor thus prepared is the *lake*: pour off the water; and ſtir the *lake* in two gallons of hard ſpring water, and mix the ſediment in two gallons of freſh water; let this method be repeated four or five times. If no hard water can be procured, or the *lake* appears too purple, half an ounce of alum ſhould be added to each quantity of water before it be uſed. Having thus ſufficiently freed the *lake* from the ſalts, drain off the water through a filtre, covered with a worn linen cloth. When it has been drained to a proper dryneſs, let it be dropped through a proper funnel on clean boards, and the drops will become ſmall cones or pyramids, in which form the *lake* muſt be ſuffered to dry, and the preparation is completed.

Lake may be prepared from cochineal, by gently boiling two ounces of cochineal in a quart of water; filtering the ſolution through paper, and adding two ounces of pearl-aſhes diſſolved in half a pint of warm water and filtered through paper. Make a ſolution of cuttle-bone as in the former proceſs; and to a pint of it add two ounces of alum diſſolved in half a pint of water. Put this mixture gradually to that of the cochineal and pearl-aſhes, as long as any ebullition appears to ariſe, and proceed as above. A beautiful *lake* may be prepared from Brazil wood, by boiling three pounds of it, for an hour in a ſolution of three pounds of common ſalt, in three gallons of water; and filtering the hot fluid through paper: add to this a ſolution of five pounds of alum in three gallons of water. Diſſolve three pounds of the beſt pearl-aſhes in a gallon and a half of water, and purify it by filtering; put this gradually to the other, till the whole of the colour appear to be precipitated, and the fluid be left clear and colourleſs. But if any appearance of purple be ſeen, add a freſh quantity of the ſolution of alum by degrees, till a ſcarlet hue be produced. Then purſue the directions given in the firſt proceſs with regard to the ſediment. If half a pound of ſcarlet rags be added to the ſolution of pearl-aſhes, and diſſolved before its purification by the filtre, and two pounds of the wood, and a proportional quantity of the common ſalt and water be uſed in the coloured ſolution, a *lake* will be produced that will ſtand well in oil; but it is not ſo tranſparent in oil as without the ſcarlet. *Lake* with Braſil wood may be alſo made by adding half an ounce of anotto to each pound of the wood; the anotto muſt be diſſolved in the ſolution of pearl-aſhes. There is a kind of beautiful *lake* brought from China; but as it does not mix well with either water or oil, though it diſſolves entirely in ſpirit of wine, it is not of any uſe in our kinds of painting. This has been erroneouſly called ſaflower. Handmaid to the Arts, v. 1. p. 61, *&c.*

LAKE, *Orange*, is the tinging part of anotto precipitated together with the earth of alum. This pigment which

is of a bright orange colour, and fit for varnish painting, where there is no fear of flying, and also for putting under crystal to imitate the vinegar garnet. may be prepared, by boiling four ounces of the best anotto and one pound of pearl-ashes half an hour in a gallon of water; and straining the solution through paper. Mix gradually with this a solution of a pound and a half of alum in another gallon of water; dessiling, when no ebullition attends the commixture. Treat the sediment in the manner already directed for other kinds of *lake*, and dry it in square bits or round lozenges. Handmaid to the Arts, vol. i. p. 119.

LAKE, *rose* See *Rose* PINK.

LAKE of *madder*. See MADDER.

LAKE-*weed*, in *Botany*. See ARSMART.

LAMA, or LAMAS, the title of an order of priests among the western Tartars, on the frontiers of China, who are held in great veneration.

They have a grand *lama*, who is their high-priest, and who is the second person in the kingdom, being the next in authority to the king. He receives homage, and adoration, not only from the people, but from the neighbouring kings; none of whom are ever inthroned, without sending ambassadors to him to obtain his benediction.

The more remote Tartars absolutely regard him as the deity himself. They believe him immortal and endowed with all knowledge and virtue. They come up every year from different parts to worship and make rich offerings at his shrine. The orthodox opinion is, that when the grand *lama* seems to die, either of old age or infirmity, his soul in fact only quits a crazy habitation to look for another, younger or better; and it is discovered again in the body of some child, by certain tokens known only to the *lamas* or priests, in which order he always appears.

The *lamas* are extremely superstitious, and are remarkably addicted to magic. See Phil. Trans. vol. lxvii. p. 2. art. 25.

LAMAC, a word used by some authors to express gum arabic.

LAMARE, a word used by some of the chemical writers as a name for sulphur.

LAMB, in *Zoology*, the young of the sheep kind. See SHEEP.

A male lamb of the first year is called a wedder hog, and the female, a ewe hog; the second year it is called a wedder, and the female a shearc. If a lamb be sick, mare's milk with water may be given it, and by blowing into the mouth many have been recovered after appearing dead. The best season for weaning them is when they are fifteen or eighteen weeks old; and about Michaelmas the males should be separated from the females; and such males as are not designed for rams, gelded. See PASCHAL *Lamb*.

LAMB-*earth*, in *Husbandry*, is a whitish stony loam. The name seems only a corruption of the word *loam-earth*. It is a clay, with an admixture of that sort of stony matter which usually constitutes lime-stone, of fragments of lime-stone, and of many smaller pieces of a stony matter, of a less firm concretion. These stones are all of much the same colour with the earth, and the whole easily breaks and moulders upon putting water to it. It has usually an admixture of sea-shells also in it, and, while in the stratum, is so hard, as scarce to be cut by a spade. It is in great esteem in many counties of England for making the earthen floors of barns, and other such uses.

LAMB's *lettuce*. See VALERIAN.

LAMBATIVES, or rather LAMBITIVES, a form of medicine to be licked off the end of a liquorice-stick.

Lambatives amount to the same with *linctuses*, *lohocks*, and *electuaries*.

LAMBDOIDES, Λαμβδοειδὴς, in *Anatomy*, an epithet applied to the third proper SUTURE of the cranium, in regard it resembles the form of a Greek Λ, *lambda*.

For the same reason it is sometimes called ypsiloides, as bearing some resemblance to the Greek Υ, *upsilon*.

LAMBENT *fire*. See FIRE.

LAMBERT's *blue*. See AZURE and BLUE *ultramarine*.

LAME, in the *Manege*, is used in several phrases of that art; as *lame of an ear*, called in French *boiteux de l'oreille*, is said of a horse, when he halts upon a walk or trot, and keeps time to his halting with the motions of his head; for all *lame* horses do not keep time in that manner. See HALTING.

LAME *of the bridle*, is used by way of raillery, to signify the same thing.

LAMELLÆ, derived of *lamina*, and signifying as much as *little laminæ*; little, thin plates, or laminæ, whereof the scales and shells of fishes, &c. are composed.

LAMENESS, *claudicatio*, in *Surgery*. We want a chirurgical treatise on *lameness*: no person has as yet enquired into the various causes, and the proper remedies adapted to them, in cases of *lameness*; and in some instances remedies may be efficaciously applied.

Lameness arises from a variety of causes. From native deformity, or from the thigh being put out of joint in the birth; from the bad conformation of the cotyloid cavity of the ossa innominata; from the weakness of the hips; from external accidents; and from diseases. See LUXATION.

Natural *lameness* is incurable, but the *lameness* of the mother does not generally descend to the children; nevertheless it may sometimes be communicated by causes difficult to discover. Zwinger tells us of a *lame* woman who brought three children into the world, afflicted with the same infirmity.

In all the species of accidental luxation of the thigh, as well as in fractures, the action of limping is unavoidable; and is only to be cured by a skilful reduction: sometimes a simple blow or a slight fall, will occasion a species of luxation of the thigh bone, in which an effusion of the mucilage, and a relaxation of the ligaments ensuing, the bone is driven out of its place, and occasions absolute *lameness*: and sometimes the unskilful treatment of a surgeon is the only cause.

A leg or a thigh too long or too short, occasioned by violence in bringing an infant into the world, will make it halt all the days of its life, if an attempt be not made in proper time toward a cure, by endeavouring to restore the joint to its natural socket.

The leg or thigh, when grown too short by the contraction of those parts, for want of radical moisture, in consequence of some disorder, produces an incurable *lameness*. It is the same in a relaxation of the ligaments, which is sometimes caused by a sciatic humour. If a schirrus is formed in one of the rems, the thigh of the same side will become paralytic, or incurably *lame*. Sometimes it happens without what is called a luxation, that the leg, merely by a contraction or rigidity of the muscles which serve to put it in motion, shrinks to that degree, that it cannot be moved without halting. The remedy for such a complaint, is to employ emollient fomentations, together with resolutive spirits, mollifying baths, purging with mineral waters, and to wear a shoe with a leaden sole, of a weight proportioned to the contraction of the limbs.

A weakness of the hips will occasion a *lameness* of both sides. This misfortune is frequently owing to nurses, who put children to walk without assistance, before their parts have acquired sufficient strength and firmness to sustain the weight of their body.

As soon as this weakness discovers itself, it may be corrected by having recourse to a girdle round the waist, which taking in the whole swell of the belly, is well braced at the hips; this girdle will give strength in walking, by fortifying the loins. They ought also to be bathed several times a day for some months with astringent decoctions.

LAMENTATIONS, a canonical book of the Old Testament, written by the prophet Jeremiah, according to archbishop Usher and some other learned men who follow the opinion of Josephus and St. Jerom, on occasion of Josiah's death. But this opinion does not seem to agree with the subject of the book, the lamentation composed by Jeremiah on that occasion being probably lost. The fifty-second chapter of the book of Jeremiah was probably added by Ezra, as a preface or introduction to the *Lamentations*: the two first chapters are employed in describing the calamities of the siege of Jerusalem: in the third the author deplores the persecutions he himself had suffered: the fourth treats of the desolation of the city and temple, and the misfortune of Zedekiah: the fifth chapter is a prayer for the Jews in their dispersion and captivity: and at the close of all he speaks of the cruelty of the Edomites, who had insulted Jerusalem in her misery. All the chapters of this book, except the last, are in metre, and digested in the order of the alphabet, with this difference, that in the first, second, and fourth chapters, the first letter of every verse follows the order of the alphabet; but in the third the same initial letter is continued for three verses together. This order was probably adopted, that the book might be more easily learnt and retained. The subject of this book is of the most moving kind; and the style throughout lively, pathetic, and affecting. In this kind of writing the prophet Jeremiah was a great master, according to the character which Grotius gives of him: *Mirus in affectibus concitandis*.

LAMIA. See SHARK.

LAMIÆ, *Λαμιαι*, among the *Ancients*, a kind of demons, or evil spirits, who, under the form of beautiful women, are said to have devoured children.

Horace makes mention of them in his Art of Poetry.—Some authors call them *Lamiæ*, *à lanitando*. Philostratus says, they are also called *Larvæ*, or *Lemures*, as if they were all the same. Bochart will have the word to be

be Phœnician, and derived it from לחם *to devour*; alledging, that the fable of the *Lamiæ* came from Libya.

LAMINÆ, in *Physiology*, thin plates, or tables, whereof any thing consists: particularly the human skull, which are two, the one laid over the other.

LAMIODONTES, is the name given by Dr. Hill to the GLOSSOPETRÆ.

LAMIOLA, in *Ichthyology*, a name by which some authors have called the MALTHA or forrar, a kind of shark.

LAMIOLA is also the name given by the modern Italians to a fish called in Cornwall the *tope*. It is a species of the squalus, called by the generality of authors *galeus canis*; and by Artedi the *squalus*, with the nostrils placed near the mouth, and with the small foramina near the eyes.

LAMIUM, *dead nettle*, in *Botany*. See ARCHANGEL.

LAMIUM *exoticum*, in *Botany*, a name given to a species of cassida. See SKULL-*cap*.

LAMMAS-DAY, the first of August; so called, as some will have it, because lambs then grow out of season, as being too big. Others derive it from a Saxon word, signifying *loaf-mass*, because on that day our forefathers made an offering of bread prepared with new wheat.

On this day, the tenants who formerly held lands of the cathedral church in York, were bound by their tenure to bring a lamb alive into the church at high mass.

It is celebrated by the Romish church in memory of St. Peter's imprisonment.

LAMNE, in *Ichthyology*, a name given by Appian, and some other of the old Greek authors, to the common SHARK, or, as we usually call it, the *white shark*, the *lamia* and *canes carcharias* of authors. This is properly a species of SQUALUS, and is accurately distinguished by Artedi under the name of the *squalus*, with a flat back, and with numerous teeth serrated at the edges.

LAMP, *Λαμπας*, a sort of luminary, consisting of oil disposed with a wick in a proper vessel for burning. See LENS.

The use of lighted *lamps* in churches, and places of devotion, is very ancient. In the city of Fez is a mosque, wherein are nine hundred brazen *lamps* burning every night. In Turky, all the illuminations are made only with *lamps*. Polydore Virgil ascribes the first invention of *lamps* to the Egyptians; and Herodotus describes a feast of *lamps* held annually in Egypt.

Kircher shews the manner of preparing *lamps*, which shall diffuse a light so disposed, as to make the faces of those present appear black, blue, red, or of any other colour.

There has been a great dispute among the learned about the sepulchral *lamps* of the ancients: some maintain, they had the secret of making *lamps* that were inextinguishable, alledging several that had been found burning, at the opening of tombs fifteen or sixteen hundred years old. But others treat these relations as fables; and others think, that the *lamps*, which before were extinguished, took light afresh upon the admission of fresh air.

Dr. Plott, however, is of opinion such perpetual *lamps* are things practicable, and has himself made some proposals of this kind. The linum albestinum, he thinks, may do pretty well for the wick, and that the naphta, or liquid bitumen, constantly springing into some of the coal-mines, would answer for the oil.

If the asbestos will not make a perpetual wick, he thinks there is no matter in the world that will; and argues, that the tradition of such *lamps* must be fabulous, or else that they made them without wicks.

Such a *lamp* he thinks it possible to make of the bitumen springing into the coal-mines at Pitchford, in Shropshire; which, he says, like other liquid bitumens, will burn without a wick.

Those *lamps* that kindle on the immission of fresh air, the same author thinks, might be imitated by inclosing some of the liquid phosphorus in the recipient of an air-pump; which, under those circumstances, will not shine at all; but on letting the air into the recipient, there will possibly, says he, appear as good a perpetual *lamp*, as some that have been found in the sepulchres of the ancients.

LAMP, *Gordon's*, is a contrivance of an author of that name, which furnishes itself with its own oil.

It consists of a little column of brass, tin, or the like, well closed every where, excepting a small aperture at bottom, in the middle of a little gullet or canal, where the wick is placed.

Here the oil cannot get out, but in proportion as it wastes, and so opens the passage of that little aperture.

This kind of *lamp* was much in use some years ago; but it has several inconveniences: such as that the air gets into it by flaws and gluts; and that when the air in the cavity comes to be much rarefied by heat, it drives out too much oil, so as sometimes to extinguish the *lamp*.

Dr. Hook, and Mr. Boyle, have invented other *lamps*, that have all the conveniences of Cardan's without the inconveniences.

The flame in a *lamp* never consumes the wick, till the wick be exposed to the air by the flame's falling downward; and from hence it may be inferred, that a way found out to keep the fuel, and consequently the flame, at the same height upon the wick, would make it last a long time. Many ways have been devised to arrive at this, but it seems only possible to be done, in any degree of perfection, by hydrostatics. Thus, let a *lamp* be made two or three inches deep, with a pipe coming from the bottom almost as high as the top of the vessel; let it be filled to high with water, as to cover the hole of the pipe at the bottom, to the end that the oil may not run in at the pipe, and so be lost. Then let the oil be poured in, so as to fill the vessel almost brim full, which must have a cover, pierced with as many holes as there are wicks designed. When the vessel is thus filled, and the wicks are lighted, if water falls in by drops at the pipes, it will always keep the oil at the same height, or very near; the weight of the water being to that of the oil as 28½ to 19, which in two or three inches makes no great difference. If the water runs faster than the oil wastes, it will only run over at the top of the pipe, and what does not run over will come under the oil, and keep it at the same height. Phil. Trans. N° 245. p. 388.

By 17 Geo. II. cap. 29. a convenient number of glass *lamps* shall be put in such places of the city of London, as the mayor, aldermen, and commonalty, shall think fit; to be kept lighted and burning from sun-set to sun-rising throughout the year; and rates shall be made not exceeding 6*d.* in the pound, nor above 30*s.* a year on any one person, for defraying the charges of them. Every alderman, with consent of his deputy and common council, may contract yearly for the setting up *lamps*, and their lighting, trimming, &c. and persons maliciously breaking down, or extinguishing any *lamp*, shall forfeit 40*s.* for the first offence, 50*s.* for the second, and 3*l.* for the third, leviable by justices, or to be sent to the house of correction. None but British oil is to be used for *lamps* in private houses, under penalty of 40*s.* 8 Ann. cap. 9.

LAMP, *rolling*, in *Mechanics*, is a *lamp* AB (*Tab.* IV. *Mechanics*, *fig.* 48.) that has within it the two moveable circles DE and FG, whose common center of motion is at K, where their axes of motion cross one another, in which point also is their common center of gravity. If to the inward circle you join within side the lamp KC, made pretty heavy, and moveable about its axis HI, whose center of gravity is at C, the common center of gravity of the whole machine will fall between K and C, and by reason of the pivots A, B, D, E, H, I, will be always at liberty to descend; and therefore let the whole *lamp* be rolled along the ground, or moved in any manner, the flame will always be uppermost, and the oil cannot be spilt. In this manner the compass is hung at sea; and thus should all the moon-lanthorns be made that are carried upon a pole before coaches or carriages which travel in the night. Desag. Exp. Phil. vol. I. p. 57.

LAMP *black*. See BLACK.

LAMP. *oil de*. See OIL.

LAMP, *enamelling by*. See ENAMELLING.

LAMP, *fire of a*. See FIRE.

LAMP *furnace*. See *Lamp* FURNACE.

LAMPADARY, *lampadarius*, an officer in the ancient church of Constantinople, whose business was to see the church well lighted, and to bear a taper before the emperor, the empress, and the patriarch, when they went to church or in procession.

The taper borne by the *lampadary* before the emperor was encompassed with divers circles of gold, in manner of crowns; those held before the empress and patriarch had but one. It seems they were made in those figures, and were intended to keep those great lights steady, that their light was to illumine those whose stations. There were also *lampadaries* in the emperor's palace, and others in the houses of the grandees, who had the privilege of having a *lampadary*, or torch-bearer, and only granted to the principal officers of the empire, and the chief magistrates; but afterwards the emperor followed it to other inferior officers, as questors, &c.

Together with the taper, they bore before the emperor the emperor's image, &c. And it is very probable, it was on account of this image, that they were not permitted to have a *lampadary*.

LAMPADIAS is used by some authors for a kind of blazing comet, which, as they pretend, resembles a burning *lamp*, being of several shapes; its flame or blaze tapering upward sometimes like unto a sword, and being at other times double or triple pointed.

LAM-

LAMPAS, or LAMPERS, a kind of ſwelling in the palate of a horſe; ſo called, becauſe it is cured by burning with a lamp, or a hot iron.

The *lampas* is an inflammation or tumor in the roof of a horſe's mouth, behind the nippers of the upper jaw. It ariſes from abundance of blood reſorting to the firſt furrow of the mouth, near the fore-teeth, which cauſes that furrow to ſwell as high as his gatherers; it hinders the beaſt's feeding, and makes him let his meat fall, half chewed, out of his mouth.

The *lampas* is a natural infirmity, which every horſe has firſt or laſt, and which every farrier can cure.

LAMPERN, in *Ichthyology*, a river fiſh, being the *petromyzon branchialis* of Linnæus, found in many parts of England, particularly in Oxfordſhire, and the neighbouring counties, and there called the *pride of the Iſis*. The Latin authors call it the *lampetra parva*, and *muſtela fluviatilis*. It is a ſmall fiſh, of a browniſh or bluiſh black upon the back, and a fine ſilver white on the belly, divided from the mouth to the anus with a ſtraight line; its mouth is circular or elliptic, and furniſhed with ſix or ſeven teeth, and over theſe a ſmall ſemicircular bone; in the middle of the head it has a hollow or ſmall tube, like the whale; the uſe of this is to admit the water and air, while the mouth is applied cloſe to the rocks; its gills are ſeven holes on each ſide, and it has two fins on the back.

The word *lampern* is uſed by the common people in England for one ſpecies of the *lampetra*, and is not to be confounded with the other called the *lamprey*, or the *lamprey-eel*. The near alliance in ſound between the two words *Lampern* and *lamprey*, has deceived ſeveral to ſuppoſe they meant the ſame fiſh; and even ſome authors have not diſtinguiſhed them; but the determinate ſenſe of the word is this: they are the names of two fiſh, both of the genus of the *lampetra*, according to the generality of writers, and of the *petromyzon*, according to the new ſyſtem of Artedi.

No *lamperns* are to be taken in the rivers Thames and Medway, except from Auguſt 24 to March 30. 30 Geo. II. cap. 21.

LAMPETIANS, LAMPETIANI, a ſect of ancient hereties, in the ſeventh century, who fell in with ſome of the opinions of the Arians.

Their founder, Lampetius, is ſaid to have been one of the chiefs of the Marcionites. They condemned all kind of vows, particularly that of obedience, as inconſiſtent with the liberty of the ſons of God.

LAMPETRA *Indica*, in *Ichthyology*, the name of an Eaſt Indian fiſh of the lamprey kind, caught in ſtanding waters, and called by the Dutch there *bont eel*, and *neegen oog*, or *nine eyes*.

LAMPREY, *lampetra*, a *lambendo petras*, becauſe this ſpecies is ſuppoſed to lick the rocks, in *Ichthyology*, belongs, in the Artedian and Linnæan ſyſtems, to the genus of PETROMYZON. The diſtinguiſhing characters of the common *lamprey*, or *petromyzon marinus* of Linnæus, are theſe: its back is of a blackiſh hue, with ſome angular whitiſh ſpots; the ſkin is tough, but much thinner than that of the eel; its mouth is rounded, and it lays ſo faſt hold of rocks, or wood, with this, that it ſeems to ſuck them, and ſticks ſo firmly, as not to be eaſily removed; it can, however, contract this mouth lengthwiſe, and ſhut it at pleaſure; it has a white ſpot in the middle of its forehead, between the eyes, and before that a hole, ſurrounded with a thin membrane, by which it admits the water and air, while its mouth lies cloſely on the rock; the gills are placed within ſeven round holes on each ſide, and the edge of its mouth is ſurrounded with a range of ſhort fibrillæ, which have by ſome been miſtaken for teeth; but are really of no other uſe than to affix its mouth the more firmly; its teeth are placed within its mouth, and there are twenty rows of them, the inner ones being the larger; theſe are diſpoſed in rows from the center toward the circumference, and are five, ſix, or ſeven in a row. See *Tab.* II. *Fiſh*, N° 17.

It is a fiſh that equally lives in ſalt and freſh water. In the month of March it commonly runs up into the rivers, and is then moſt valuable for the table, as being fat and full of eggs; ſo that the beſt ſeaſon for *lampreys* is in the months of March, April, and May, becauſe they are moſt firm when they firſt leave the ſalt-water, and become waſted and flabby at the approach of hot weather; they are found in ſeveral of our rivers, but the Severn is the moſt noted for them. They are taken in nets along with ſalmon and ſhad, and ſometimes in weels laid in the bottom of the river. It has been an old cuſtom for the city of Gloucester, annually, to preſent his majeſty with a *lamprey* pye, covered with a large raiſed cruſt; and as the gift is made at Chriſtmas, the corporation procure freſh *lampreys* at that time with great difficulty. They are reckoned a great delicacy, either potted or ſtewed; but are a ſurfeiting food, as one of our monarchs fatally experienced, Henry the firſt's death being occaſioned by a too full meal of this fiſh. They are ſometimes found ſo large as to weigh four or five pounds. The leſſer *lampreys*, or *petromyzon fluviatilis* of Linnæus, ſometimes grows to the length of ten inches. Its mouth is formed like that of the preceding; on the upper part is a large bifurcated tooth; on each ſide are three rows of very ſmall ones; on the lower part are ſeven teeth, the exterior of which on each ſide is the largeſt; the irides are yellow; it has the ſame orifice between the eyes with the other ſpecies; on the lower part of the back is a narrow fin, beneath which riſes another, which at the beginning is high and angular, then grows narrow, ſurrounds the tail, and ends near the anus; the colour of the back is brown or duſky, ſometimes mixed with blue; the whole underſide is ſilvery. Theſe are found in the Thames, Severn, and Dee, and are potted with the larger ſpecies, and are reckoned of a milder taſte. They are ſold to the Dutch as bait for their cod-fiſhery. Above 450,000 have been ſold in a ſeaſon at 40*s.* per thouſand. Of late, about 100,000 have been ſent to Harwich for the ſame purpoſe. It is ſaid the Dutch have the ſecret of preſerving them till the turbot fiſhery. The other ſpecies is the LAMPERN, already deſcribed.

LAMPRILLON, or LAMPREYON, a name by which ſome authors have called that particular ſpecies of *lamprey*, which we by way of diſtinction call LAMPERN.

LAMPROPHORUS, an appellation anciently given to the neophytes, during the ſeven days that ſucceeded their baptiſm.

In the ceremony of baptiſm, the new Chriſtian was clothed with a white robe, which he wore for the week following; and was thence called *lampropheros*, which ſignifies a *perſon wearing a ſhining garment*; from λαμπρος, *ſhining*, and φερω, *I bear*.

The Greeks alſo gave this name to the day of the reſurrection, becauſe their houſes were adorned and illuminated on that day with a great number of torches, as a ſymbol of the light which that myſtery diffuſed in the world.

LAMPSANA, in *Botany*. See NIPPLE-*wort*.

LAMPUGA, in *Ichthyology*, a name given by ſome authors to the fiſh more uſually known by the name of STROMATEUS.

LAMPUGO, in *Ichthyography*, a name given by many to the HIPPURUS, a ſea-fiſh, caught on the coaſt of Spain, and ſuppoſed by ſome to be the ſame with the DORADO.

LAMPYRIS, in *Natural Hiſtory*, a genus of the *coleoptera* claſs of inſects; the antennæ of which are filiform, the elytra flexile, the thorax plane and ſemiorbiculated, covering and ſurrounding the head, and the ſides of the abdomen are covered with folds of down. Linnæus enumerates eighteen ſpecies. See GLOW-*worm*.

LANÆ *petra*. See PETRA.

LANARIA, or *Herba* LANARIA, in *Botany*, a name given by the ancient Romans to a plant called *ſtruthium* by the Greeks, and uſed in the cleanſing of wool. The plant was of the thiſtle kind, and had large roots, and very prickly leaves. Some have ſuppoſed that the *chaſuſa* of the ancients was the ſame with the *lanaria herba*, or *ſtruthium*; but this appears to be a great error; for the *chaſuſa* of the Greeks is the *antirrhinum* of the Latins, which Pliny deſcribes to have leaves like flax.

LANATA, in *Botany*, a name given by Cordus, and ſome other authors, to the *aria Theophraſti*, or *white beam-tree*.

LANCARIM *ſpring*, the name of a medicated water of Glamorganſhire. It has its name from a town near which it riſes, and has been very long famous in the place for the cure of the king's evil. The body of water is about an ell broad, and runs between two hills covered with wood. About twelve yards from this ſpring the rill falls from a rock of about eight or nine feet high, with a conſiderable noiſe. The ſpring is very clear, and riſes out of a pure white marl. The cures that have been performed there are proofs of a real power in the water; but there is ſome queſtion, whether the water, or its motion and coldneſs, does the good; for the people, who come for relief, always drink of the ſpring, and bathe the part afterwards in the fall below. It is generally ſuppoſed that the lime-ſtone rocks communicate a virtue to it, by which it cures internally; but it has been often found, that the holding a limb diſordered with the evil, in the ſtrong current of a mill-tail, has cured it; and there is the ſame advantage in the fall of this water. Phil. Tranſ. N° 233. or Abr. vol. ii. p. 333.

LANCASTER, *county palatine of*. See COUNTY.

LANCASTER, *duchy court of*. See COURT.

LANCE, *Lancea*, a ſpear; an offenſive weapon, borne by the ancient cavaliers, in form of a half pike.

The *lance* conſiſted of three parts, the ſhaft, or handle, the

the wings, and the dart. Pliny attributes the invention of *lances* to the Etolians. But Varro, and Aulus Gellius, say, the word *lance* is Spanish; whence others conclude the use of this weapon was borrowed by the people of Italy from the Spaniards. Diodorus Siculus derives it from the Gaulish, and Festus from the Greek λογχη, which signifies the same.

LANCEA *Christi*, in *Botany*, a name given by some authors to the *ophioglossum*, or adder's tongue, a small herb found in moist places, with a single stem of seeds.

LANCEARII, in *Middle Age Writers*, soldiers whose chief weapon was the lance. They were in great esteem formerly.

LANCEOLA, in *Botany*, a name given by some authors to that species of plantain called *rib-wort*, or *plantago quinquenervia*, by most authors.

LANCEOLATED *leaf*, among *Botanists*. See LEAF.

LANCET, a name given by the ancient laws of England to a kind of vassals, who were obliged to work for the lord one day in a week, from Michaelmas to autumn, either with fork, spade, or flail, at the option of the lord.

LANCETTE, or LANCET, a fine, small surgeon's knife; strait-pointed, and two-edged; used in opening veins, &c. See PHLEBOTOMY.

LANCH, in *Sea Language*, a peculiar kind of *long-boat*, employed by ships in the Mediterranean sea. It is longer, lower, and more flat-bottomed than the long boat, and, though less fit for sailing, better adapted for approaching a flat shore. It is also, by its construction, fitter to under-run the cable than the long-boat, which adapts it to the harbours of the Levant sea, where the cables of different ships are fastened across each other.

LANCH *of a ship*. See LAUNCH.

LAND, in a general sense. See EARTH, SOIL, &c.

Dr. Davenant, from a scheme of Mr. King, states the quantity of *land* in England and Wales to be thirty-nine millions of acres; which, reckoning the number of inhabitants, as he does, to be 5,500,000, will at an average be 7¾ acres per head. Davenant's Works, vol. vi. p. 3. See ACRE, and EXPECTATION *of life*.

LAND, in a *Legal Sense*, includes not only the face of the earth, but every thing under or over it; so that if a man grants all his *lands*, he grants thereby all his mines of metal and other fossils, his woods, his waters, and his houses, as well as his fields and meadows.

LAND, *inclosing of*. Inclosing of *lands*, and dividing the same into several fields for pasture and tillage, is one of the principal ways of improvement; first, by ascertaining to every man his just property, and thereby preventing an infinity of trespasses and injuries that *lands* in common are subject unto, beside the disadvantage of being obliged to keep the same seasons with the other people who have *land* in the same field; so that the sowing, fallowing, and tilling the ground, must be equally performed by all the landholders; and when there happens a slothful negligent person, who has *land* intermixed with others, it is one of the greatest nuisances imaginable. Secondly, where *land* is properly inclosed, and the hedge-rows planted with timber trees, &c. it preserves the land warm, and defends and shelters it from the violent cold nipping winds, which, in severe winters, destroy much of the corn, pulse, or whatever grows on the champain grounds; and where it is laid down for pasture, it yields much more grass than the open fields, and the grass will begin to grow much sooner in the spring. The hedges and trees also afford shelter for the cattle from the cold winds in winter, and shade for them in the great heats of summer. These hedges also afford the diligent husbandman plenty of fuel, as also plough boot, cart boot, &c. And where they are carefully planted and preserved, furnish him with mast for his swine; or where the hedge-rows are planted with fruit trees, there will be a supply of fruit for cyder, perry, &c. which in most parts of England are of no small advantage to the husbandman.

By this method of inclosing, there is also much more employment for the poor, and it is therefore a good remedy against beggary; for in those open countries, where there are great downs, commons, heaths, and wastes, there is nothing but poverty and idleness to be seen amongst the generality of their inhabitants. Miller.

It must be acknowledged, that inclosures of waste *lands* and commons would be useful, if they were divided into small parcels, and given up to be occupied at moderate rents by the poor. But if besides lessening the produce of fine wool, they bear hard on the poor, by depriving them of a part of their subsistence, and only serve to increase farms already too large, which is commonly the case, the advantages attending them may not much exceed the disadvantages. With respect to inclosures of open fields and *lands*, the advocates for inclosing are ready to own, that these diminish tillage, increase the monopolies of farms, raise the prices of provisions, and produce depopulation. Such inclosures, therefore, however gainful they may be at present to a few individuals, are undoubtedly pernicious. It is a known fact, that in Northamptonshire and Leicestershire, where inclosing has greatly prevailed, most of the inclosed lordships are converted into pasturage; in consequence of which, many lordships have not now fifty acres ploughed yearly, in which fifteen hundred, or at least a thousand, were ploughed formerly; and scarce an ear of corn is to be seen in some that bore hundreds of quarters; the effect of which has been, that the price of wheat and malt is nearly doubled, and that the inhabitants in almost all the inclosed villages, where they have no considerable manufacture, are very sensibly diminished; insomuch that a hundred houses and families have in some places dwindled into eight or ten; and the landholders, in most parishes that have been inclosed only fifteen or twenty years, are very few in comparison of the numbers who occupied them in their open-field state. It is no uncommon thing to see four or five wealthy graziers engrossing a large inclosed lordship, which was before in the hands of twenty or thirty farmers, and as many smaller tenants or proprietors. All these are hereby thrown out of their livings, with their families, and many other families which were employed and supported by them. The state of Norfolk is in some respects similar to this. Inclosures, says the celebrated lord Bacon, in his History of the Reign of Henry VII. (see his Works, vol. iii. p. 431.) began in 1489 to be more frequent, whereby arable land was turned into pasture, which was easily managed by a few herdsmen. This fired a decay of people. In remedying this inconvenience, the king's wisdom and the parliament's was admirable. Inclosures they would not forbid, and tillage they would not compel; but they took a course to take away depopulating inclosures, and depopulating pasturage by consequence. The ordinance was, that all houses of husbandry, with twenty acres of ground to them, should be kept up for ever, together with a competent proportion of land to be occupied with them, and in no wise to be severed from them. By these means, the houses being kept up, did, of necessity, enforce a dweller; and the proportion of land for occupation being also kept up, did, of necessity, enforce that dweller not to be a beggar. This statute was renewed in king Henry the eighth's time; and every person who converted tillage into pasture subjected to a forfeiture of half the land, till the offence was removed. In a law of the twenty-fifth of the same reign, it is set forth, that many farms, and great plenty of cattle, particularly sheep, had been gathered into few hands, whereby the rents of lands had been increased, and tillage very much decayed; churches and towns pulled down; the price of provisions greatly enhanced, and a marvellous number of people rendered incapable of maintaining themselves and families; and, therefore, it was enacted, that no person should keep above two thousand sheep, nor hold more than two farms. In the third of Edw. VI. a bill was brought in for the benefit of the poor, for rebuilding decayed farm-houses, and maintaining tillage against too much inclosing. In the year 1638 there was a special commission from Charles I. for enforcing the statute of the 39th of Elizabeth, by which no cottage was allowed in any country place, without at least four acres of land to it, to prevent the increase of the poor, by securing to them a maintenance; nor were any inmates allowed in any cottage, to secure the full cultivation of the *land*, by diffusing the people more over it. And by an act in Cromwell's time, no new house was to be built within ten miles of London, unless there were four acres of *land* occupied by the tenant. Thus did the policy of our ancestors discourage inclosing and engrossing, upon the same general view of their depopulating tendency; and though the increase of trade and manufactures in more modern times has produced a considerable alteration in the state of our country, and may require some change in our internal policy, yet it is easy to observe, that facts justify the apprehension, that inclosing and engrossing to the degree in which they have lately prevailed will annihilate the small occupiers of land, and reduce the inhabitants of the kingdom to two classes, the gentry and beggars, or grandees and slaves.

As in former times the number of the occupiers of land was greater, and all had more opportunities of subsisting for themselves, it is reasonable to conclude, that the number of people willing to work for others must have been smaller, and the price of day-labour higher. The principal price of day-labour is at present no more than about four times, or at most five times, higher than it was in the year 1514. But the price of corn is seven times, and of flesh-meat and raiment about fifteen times higher; therefore the price of labour has been so far from advancing

vancing in proportion to the increaſe in the expences of living, that it does not appear to bear now half the proportion to theſe expences that it did formerly. See on this ſubject Price's Obſervations on Reverſionary Payments. Supplement, p. 388. &c. Appeal to the Public on the Subject of the National Debt, p. 93. &c.

In incloſing of *land*, regard ſhould be had to the nature of the ſoil, and what it is intended for; becauſe corn land ſhould not be divided into ſmall fields; for beſides the loſs of ground in hedges, &c. the corn doth ſeldom thrive ſo well in ſmall incloſures as in more open *land*, eſpecially where the trees are large in the hedge-rows. The graſs alſo in paſture is not ſo ſweet near hedges, or under the drip of trees, as in an open expoſure; ſo that where the incloſures are made too ſmall, or the land over planted with trees, the herbage will not be near ſo good, nor in ſo great plenty, as in larger fields; therefore, before a perſon begins to incloſe, he ſhould well conſider how he may do it to the greateſt advantage: as, for inſtance, it is always neceſſary to have ſome ſmaller incloſures near the habitation, for the ſhelter of cattle, and the conveniency of ſhifting them from one field to another, as the ſeaſon of the year may require; and hereby the habitation, barns, ſtables, and out-houſes, will be better defended from ſtrong winds, which often do great damage to thoſe that are expoſed to their fury. Theſe ſmall incloſures may be of ſeveral dimenſions, ſome of them three, four, ſix, or eight acres in extent; but the larger diviſions for corn ſhould not contain leſs than twenty or thirty acres, or more, according to the ſize of the farm.

The moſt common incloſure is by a ditch and bank raiſed by its ſide with quick: this takes place in almoſt any ground; but as it is expenſive, and ſtone or water are more plentiful, they are uſed in its ſtead. In marſhy lands they only cut ditches, by way of fence between ground and ground; and theſe, when wide and deep enough, are a very good fence in all places where there is water to keep them full. In Cornwall and Devonſhire, and ſome other of the weſtern counties, they uſe a ſtone fence, which is the beſt kind both for the lands and for the cattle. Flat ſtones are very plentiful in theſe counties, and may be had at a trifling expence. With theſe ſtones they build round the land that is to be incloſed two walls near one another, laying the ſtones one upon another, firſt two and two, then one, all the way up; and as they riſe, they fill up the ſpace with earth; and ſo they continue the ſtone work, filling it to what height and breadth they pleaſe, and beating the ſtones in flat to the ſides, which makes the whole firm. On the top of theſe walls they plant quick, and even timber-trees, which thrive extremely well. In the northern counties of England, and ſome others, where there is plenty of ſtone of a large and rough kind, they make their fences with the rough and unhewn ſtones, piling them up into a wall with no ſort of cement or mortar, only laying on large ones at the top in a bed of clay, which keep all the reſt together. They make theſe walls about five feet high. See EARTH-*banks*, FENCE, HEDGE, and WALL.

LAND, *draining of*. The draining of *land* is alſo another great improvement to it; for though meadows and paſtures, which are capable of being overflowed, produce a greater quantity of herbage than dry land, yet where the wet lies too long upon the ground, the graſs will be ſour and extremely coarſe; and when there is not care taken in time to drain this *land*, it will produce little graſs, and ſoon be over-run with ruſhes and flags, ſo as to be of ſmall value.

The beſt method for draining of theſe lands is, to cut ſeveral drains acroſs the land, in thoſe places where the water is ſubject to lodge; and from theſe croſs drains to make a convenient number of other drains, to carry off the water to either ponds or rivers in the lower parts of the land. Theſe drains need not be made very large, unleſs the ground be very low, and ſo ſituated as not to be near any river to which the water may be conveyed; in which caſe there ſhould be large ditches dug at proper diſtances, in the loweſt part of the ground, to contain the water; and the earth which comes out of the ditches ſhould be equally ſpread on the land, to raiſe the ſurface. But where the water can be conveniently carried off, the beſt method is to make under-ground drains at proper diſtances, which may empty themſelves into large ditches, which are deſigned to carry off the water. This ſort of drains is the moſt convenient, and as they are hid from the ſight, do not incommode the land; nor is there any ground loſt where theſe are made.

The uſual method of making theſe drains is to dig trenches, and fill the bottoms with ſtones, bricks, ruſhes, or buſhes, which are covered over with the earth which was dug out of the trenches; but this is not the beſt method, becauſe the water has not a free paſſage through theſe drains; ſo that whenever there is a flood, they are often ſtopped by the ſoil which the water frequently brings down with it. The beſt method yet found to make theſe drains is to dig trenches to a proper depth for carrying off the water, which for the principal drains ſhould be three feet wide at their top, and ſloped down for two feet in depth, where there ſhould be a ſmall bank left on each ſide, upon which the croſs ſtakes or bearers ſhould be laid, and below theſe banks there ſhould be an open drain left, at leaſt one foot deep, and nine or ten inches wide, that there may be room for the water to paſs through: the larger drains ſhould be at convenient diſtances, and ſmaller drains of about ſix or ſeven inches wide, and the hollow under the buſhes eight or nine inches deep, ſhould be cut acroſs the ground, which ſhould diſcharge the water into theſe larger drains. The number and ſituation of them muſt be in proportion to the wetneſs of the land; and the depth of earth above the buſhes muſt alſo be proportioned to the intended uſe of the *land*; for if it is arable land to be ploughed, it muſt not be ſhallower than a foot or fourteen inches, that there may be ſufficient depth for the plough, without diſturbing the buſhes, but for paſture land nine inches will be full enough; for when the buſhes lie too deep in ſtrong *land*, they will have little effect, the ground above will bind ſo hard, as to detain the wet on the ſurface. When the drains are dug, there ſhould be prepared a quantity of good bruſh wood, the larger ſticks ſhould be cut out to lengths of about ſixteen or eighteen inches, which ſhould be laid acroſs upon the two ſide-banks of the drain, at about four inches diſtance; then cover theſe ſticks with the ſmaller bruſh-wood, furz, broom, heath, or any other kind of bruſh, laying it lengthwiſe pretty cloſe; on the top of theſe may be laid ruſhes, flags, &c. and then the earth laid on to cover the whole. This ſort of drains will continue good for a great number of years, and are never liable to the inconveniences of the other; for the water will find an eaſy paſſage through them under the buſhes; and where there is plenty of bruſh-wood, they are made at an eaſy expence; but in places where wood is ſcarce, it would be chargeable to make them: however, in this caſe, it would be a great advantage to theſe *lands* to plant a ſufficient number of cuttings of willow, or the black poplar, on ſome of the moiſt places, which would furniſh bruſh-wood for theſe purpoſes in four or five years; and as the expence of planting theſe cuttings is trifling, there cannot be a greater advantage to an eſtate which wants draining, than to practiſe this method, which is in every perſon's power, ſince there is little expence attending it.

In countries where there is plenty of ſtone, that is the beſt material for making theſe under-ground drains; for when theſe are properly made, they will never want repairing.

The beſt time of the year for making theſe drains is about Michaelmas, before the heavy rains of autumn fall, becauſe at this ſeaſon the land is uſually dry, ſo that the drains may be dug to a proper depth; for when the ground is wet it will be very difficult to dig to any depth, becauſe the water will drain in, wherever there is an opening in the ground. Miller. See BOG, DRAINS, and FEN.

By 11 Geo. II. cap. 34. 14 Geo. II. cap. 24. and 21 Geo. II. cap. 18. the ſecond offence in ſetting fire to engines for draining the ſeveral fens, to which theſe acts relate, is made felony without clergy. By 22 Geo. II. cap. 11. 16. 19. 29 Geo. II. cap. 22. 30 Geo. II. cap. 32, 33. 35, 36. 31 Geo. II. cap. 18, 19. 32 Geo. II. cap. 13. 33 Geo. II. cap. 32. offenders maliciouſly ſetting fire to any of the works for draining the ſeveral fens to which theſe acts relate, may be tranſported for ſeven years.

LAND, *flooding of*. As the draining of cold wet *lands* is a great improvement to them, ſo the floating or watering of dry looſe land is not a leſs advantage to them. This may be eaſily effected where there are rivers, or reſervoirs of water, which are ſituated above the level of the ground deſigned to be floated, by under-ground drains (made after the manner of thoſe before directed for draining of *land*) through which the water may be conveyed at proper ſeaſons, and let out on the ground: in order to this, there muſt be good ſluices made at the heads of the drains, ſo that the water may never get out, but at ſuch times as is required; for if this be not taken care of, the water, inſtead of improving the land, will greatly damage it.

The time for drowning of *land* is uſually from November to the end of April; but though this is the general practice, yet Miller ſays he cannot approve of it for many reaſons. The firſt is, that by the wet lying continually on the ground in winter, the roots of the finer ſort of graſs are rotted and deſtroyed; and by letting on of the water, at

the ſeaſon when the ſeeds of docks, and other bad weeds, which commonly grow by river ſides, are falling, theſe ſeeds are carried upon the land, where they remain and grow, and fill the ground with bad weeds, which is commonly the caſe with moſt of the water meadows in England, the graſs in general being deſtroyed; ſo that ruſhes, docks, and other trumpery, make up the burden of theſe lands; but if theſe meadows were judiciouſly managed and never floated till March or April, the quantity of ſweet good graſs would be thereby greatly increaſed, and the beautiful verdure of the meadows preſerved. Miller. See OVERFLOWING.

LAND, *burning of*. Another great improvement of *land* is by burning of it, which for four, heathy, and ruſhy land, be it either hot or cold, wet or dry, is a very great improvement; ſo that ſuch *lands* will, in two or three years after burning, yield more, excluſive of the charges, than the inheritance was worth before; but this is not to be practiſed on rich fertile land; for as the fire deſtroys the acid juice, which occaſions ſterility in the poor land, ſo it will in like manner conſume the good juices of the richer land, and thereby impoveriſh it, ſo that it hath been with great reaſon diſuſed in deep rich countries.

It is alſo a very great improvement, where land is overgrown with broom, furz, &c. to ſtub them up by the roots; and when they are dry, lay them on heaps, and cover them with the parings of the earth, and burn them, and ſpread the aſhes over the ground. By this method vaſt tracts of land, which at preſent produce little or nothing to their owners, might be made good at a ſmall expence, ſo as to become good eſtates to the proprietors. Miller. See BURNING and DENSHIRING *of land*.

LAND, *arable*. See ARABLE.

LAND, *bog*. See BOG.

LAND, *laying the*, in *Sea Language*, denotes that motion of a ſhip which increaſes its diſtance from the coaſt, ſo as to make it appear lower and ſmaller; a circumſtance ariſing from the intermediate convexity of the ſea. This is uſed in contradiſtinction to *roſhing the land*, which is produced by the oppoſite motion of approach towards it. When a ſhip is got out of ſight of *land*, they ſay the *land is laid*.

LAND, *to make the*. See MAKE.

LAND-*mark*, at *Sea*, is any mountain, rock, ſteeple, windmill, tree, or the like, near the ſea-ſide, which ſerve to direct ſhips paſſing by, how to ſteer, ſo as to avoid certain dangers, be they rocks, ſhoals, whirlpools, &c.

LAND, *ſetting the*, at *Sea*, is obſerving by the compaſs how it bears.

LAND *ſhut in*, at *Sea*. When another point of *land* hinders the ſight of that which a ſhip came from, then they ſay the *land is ſhut in*.

LAND-*to*, at *Sea*. When a ſhip lies ſo far from the ſhore, that ſhe can but juſt ken *land*, then ſhe is ſaid to lie *land-to*.

LAND-*turn*, at *Sea*, is a wind that blows from the ſhore in the night, at certain times, in moſt hot countries.

LAND, *head*, or *point of land*, in the *Sea Language*, is that which lies farther out into the ſea than the reſt. See POINT, CAPE, &c.

LAND-CHEAP, an ancient cuſtomary fine, paid either in cattle, or money, upon the alienating or ſelling of *land* in certain manors, or within the liberty of certain boroughs.

At Malden in Eſſex, a payment is ſtill made of 12*d.* in every mark of the purchaſe-money, for lands and houſes ſold in that town; which is called *land-cheap*.

LAND-FALL, is a ſea-term, ſignifying to fall in with the land, or the firſt land diſcovered after a ſea-voyage

LAND-FALL, *good*, is when a ſhip makes or ſees the land, as ſhe expected, according to her reckoning. The contrary is called a *bad land-fall*.

LAND-GABLE, an ancient term for a tax or rent, iſſuing out of a land; anſwering to what we now call *ground-rent*.

LAND-LOCKED, a ſhip is ſaid to ride *land-locked*, when ſhe is ſurrounded with land; that is, is at anchor in a place where there is no point open to the ſea, ſo that ſhe is ſafe from the violence of winds and tides.

LAND-TAX is one of the uſual annual taxes, which has ſuperſeded all the former methods of rating either property, or perſons in reſpect of their property, whether by tenths, fifteenths, ſubſidies on land, hydage or hidage, ſcutage or eſcuage, or talliage. Tenths and fifteenths were temporary aids iſſuing out of perſonal property, and granted to the king by parliament, being the real tenth or fifteenth part of all the moveables belonging to the ſubject. We meet with the payment of fifteenths as far back as the ſtatute of Magna Charta; in the concluſion of which, the parliament grants to the king, for the conceſſions made by him, a fifteenth part of all their moveable goods. This taxation was originally charged upon the ſeveral individuals, but in the 8th year of Edward III. a certain ſum was rated on every town, &c. In proceſs of time this fifteenth being inſufficient for the public exigence, the number of fifteenths was augmented to two or three fifteenths. Whenever, in later years, the commons granted the king a fifteenth, every parith in England knew their proportion of it; i. e. the ſame identical ſum that was aſſeſſed by the ſame aid in the 8th of Edward III. and then raiſed it by a rate among themſelves, and returned it into the royal exchequer. See FIFTEENTH. See alſo TENTH. The other ancient levies were in the nature of a modern *land-tax*; for we may trace the original of that charge as high as to the introduction of our military tenures; when every tenant of a knight's fee was bound, if called upon, to attend the king in his army for forty days in every year. In lieu of this perſonal attendance, a pecuniary ſatisfaction came to be levied by aſſeſſments, at ſo much for every knight's fee, under the name of ſcutages. See ESCUAGE. Of the ſame nature with theſe were the aſſeſſments of hydage or HIDAGE upon all other lands, and of TALLIAGE upon cities and boroughs. But they all gradually fell into diſuſe, upon the introduction of ſubſidies, about the time of king Richard II. and king Henry IV. See SUBSIDY. In lieu of ſubſidies, which were uſually raiſed by commiſſioners appointed by the crown, or the great officers of ſtate, the parliament, in the beginning of the civil wars, introduced the practice of laying weekly and monthly aſſeſſments of a ſpecific ſum upon the ſeveral counties of the kingdom, to be levied by a pound rate on lands and perſonal eſtates; which were occaſionally continued during the whole uſurpation, ſometimes at the rate of 120,000*l.* a month, ſometimes at inferior rates. After the Reſtoration the ancient method of granting ſubſidies, inſtead of theſe monthly aſſeſſments, was twice, and twice only renewed, viz. in 1663, when four ſubſidies were granted by the laity and four by the clergy; and in 1670, when 800,000*l.* was raiſed by way of ſubſidy, which was the laſt time of raiſing ſupplies in this manner. The monthly aſſeſſments being eſtabliſhed by cuſtom, raiſed by commiſſioners named by parliament, and producing a more certain revenue, ſubſidies were diſcontinued and occaſional aſſeſſments granted as emergencies required. Theſe periodical aſſeſſments, the ſubſidies which preceded them, and the more ancient talliage, hydage and tallinge, ſays Judge Blackſtone, were to all intents and purpoſes a *land-tax*; and the aſſeſſments were ſometimes expreſsly called ſo. However, in the year 1692 a new aſſeſſment or valuation of eſtates was made throughout the kingdom, which, though by no means a perfect one, had this effect, that a ſupply of 1*s.* in the pound was equal to 1*l.* in the pound of the value of the ſums given in. And, according to this enhanced valuation, from the year 1693 to the preſent, the *land-tax* has continued an annual charge upon the ſubject, above half the time at 4*s.* in the pound, ſometimes at 3*s.* ſometimes at 2*s.* twice, viz. in 1732 and 1733, at 1*s.* but without any total intermiſſion. The medium has been at 3*s.* in the pound, being equivalent to twenty-three ancient ſubſidies, and amounting annually to more than a million and a half of money. The method of raiſing it is by charging

charging a particular ſum upon each county, according to the valuation of 1692; and this ſum is aſſeſſed and raiſed upon the perſonal as well as the real eſtates of individuals by commiſſioners appointed in the act, being the principal landholders of the county, and their officers. The general qualification of commiſſioners in counties, with ſome few exceptions, is 100*l.* a year of landed property: theſe commiſſioners before they can act, are required to take the oaths of allegiance, ſupremacy, and abjuration. When they firſt meet they direct the return and appointment of proper aſſeſſors: at their ſecond meeting they direct them how to proceed in ſettling the ſeveral rates and charges; the aſſeſſment on perſonal eſtates ſhall be 4*s.* in the pound, according to the true yearly value of them; i. e. for every 100*l.* of ready money and debts, and for every 100*l.* worth of goods, 20*l.* excepting ſuch ſums as are owing and debts which the commiſſioner ſhall judge deſperate; and excepting ſtock upon lands and houſhold ſtuff, and debts and loans owing to his majeſty. Every perſon having a public office or employment, and their ſubſtitutes, ſhall pay 4*s.* for every 20*l.* of their ſalaries: military officers in the army or navy excepted. By 32 George II. c. 33. relating to the duty upon offices, it is provided, that in all future aſſeſſments to the *land-tax*, ſuch officers ſhall not be aſſeſſed at a higher rate to the *land-tax*, than they were in 1758. Every perſon having an annuity or penſion out of the exchequer, or out of any branch of the revenue ſhall pay 4*s.* for every 20*s.* except ſalaries charged upon lands which pay to the full, and annuities exempted by act of parliament; and except annuities paid to ſuper-annuated commiſſioners or warrant ſea-officers, or to the widows of ſea-officers ſlain in the ſervice of the crown; and except money lent to the government on the ſecurity of the act; and except turnpike tolls, and the ſalaries of turnpike officers.

Real eſtates ſhall be charged with as much equality and indifference as poſſible by a pound rate, to make up the ſeveral ſums charged by the act on each county or place. Colleges and hoſpitals are exempted, together with the buildings that are within the walls or limits of the ſame. All ſuch lands, revenues, or rents belonging to any hoſpital or alms-houſe, or ſettled to any charitable or pious uſe as were aſſeſſed in 4 W. and M. ſhall be liable: and no other lands, revenues or rents, then belonging to any hoſpital or alms-houſe, or ſettled to any charitable or pious uſe, ſhall be charged or aſſeſſed: but lands given to charities ſince the 4th W. and M. ſhall not be exempted. No poor perſon ſhall be charged, whoſe lands, &c. are not of the full yearly value of 20*s.* in the whole. The aſſeſſors themſelves are aſſeſſed by the commiſſioners. The *land-tax* ſhall be paid by the tenant, who ſhall deduct it out of his rent. Papiſts and non-jurors ſhall pay double. At the third meeting of the commiſſioners the aſſeſſors ſhall deliver duplicates of the aſſeſſment in writing, ſigned by them, to the commiſſioners, with the names of proper collectors, for whom the pariſh or place ſhall be anſwerable. One of the duplicates, ſigned by three or more commiſſioners, ſhall be delivered to the collectors, with warrant for collecting; and the time and place of appeals ſhall then be appointed. The fourth meeting is that of appeal, notice of which ſhall be given in the church; and every perſon intending to appeal ſhall give a written notice to one or more aſſeſſors, that they may attend to juſtify the aſſeſſment. The commiſſioners are empowered to give relief in caſe of over-charge, and cauſe the ſum abated to be re aſſeſſed: and when the appeal is determined, it is abſolutely final. If any perſon refuſe or neglect to pay to the collector on demand, he may levy the ſum aſſeſſed by diſtreſs and ſale of the goods of the perſon neglecting or refuſing to pay; and for want of diſtreſs, he may be committed by warrant of two commiſſioners to the common gaol, until payment of the money aſſeſſed and of the charges. The collector is required to pay the money received to the receiver-general or his deputy quarterly, on or before June 24, Sept. 29, Dec. 25, and March 25; who ſhall give a receipt gratis: the collectors are allowed 3*d.* in the pound, which they may detain out of the laſt payment; but if any collector detains the money longer than the time appointed, or pays it otherwiſe than directed, he ſhall forfeit 40*l.* and if he refuſe to pay it, two commiſſioners may impriſon him, ſeize his eſtates real and perſonal, and ſell them for payment. The receiver-general is appointed by the king, or in purſuance of his directions, and has a ſalary allowed him by the lords of the treaſury, not exceeding 2*d.* a pound; notice of his appointment is to be given to the commiſſioners, before the time of the firſt quarterly payment. The receiver, within twenty days after the receipt, ſhall pay the money into the exchequer, or forfeit 100*l.* to him who ſhall ſue. The clerks of the commiſſioners are allowed 13*d.* in the pound for writing the aſſeſſments, duplicates, &c. to be paid by the receiver-general, according to the warrant of two commiſſioners. Aſſeſſors, collectors, &c. not doing their duty may be fined by three or more commiſſioners, in any ſum not exceeding 40*l.* Blackſt. Com. vol. i. p. 308, &c. Burn's Juſtice, art. LAND-*Tax*.

LAND-WAITER, an officer of the cuſtom-houſe, whoſe duty is, upon landing any merchandize, to examine, taſte, weigh, meaſure them, &c. and to take an account thereof. In ſome ports they alſo execute the office of a coaſt waiter. They are likewiſe occaſionally ſtyled ſearchers, and are to attend and join with the patent ſearcher, in the execution of all cockets for the ſhipping of goods to be exported to foreign parts; and in cales where drawbacks on bounties are to be paid to the merchant on the exportation of any goods, they, as well as the patent ſearchers, are to certify the ſhipping thereof on the debentures.

LANDAN, in *Phyſiology*. See SARCO.

LANDED *intereſt*, a term oppoſed to moneyed intereſt, in political conſiderations; though there is a near connexion between them: for, the *landed intereſt* is affected by foreign trade.

The foreign trade of every country muſt decline, that, 1. Lays unequal taxes in general on its people. 2. That cramps its commerce, the fountain of riches, by high duties, and impolitic prohibitions. 3. That ſuffers many monopolies. 4. That oppreſſes its people by prohibiting the importation of victuals, under the pretence of raiſing the value of its lands. 5. That encourages idleneſs, by bad laws relating to its poor. 6. That tempts foreigners to carry away its coin for leſs than its intrinſic value. 7. That makes the obtaining juſtice chargeable. 8. That ſuffers a heavy national debt, contracted in time of war, to continue unpaid in time of peace.

The reaſon why the decline of foreign trade ſinks the value of land is, 1. becauſe it ſinks the markets at home. For, the produce of land being rendered exceſſively dear from the cauſes above enumerated, foreigners will not take its ſuperfluities; and labour being by the ſame cauſes rendered exceſſively dear, we cannot manufacture or improve that produce, becauſe nations which can afford cheaper ſupply the markets abroad; ſo that the produce of the lands, not being carried off as uſual, muſt become a dead ſtock on the farmer's hands, and cauſe great quantities to be crouded into markets, where, being encouragement but for few buyers, the price naturally falls; as, for inſtance, the declining demand of our woollen goods abroad falls the price of wool at home.

2. Becauſe it increaſes the number of poor, to burden the *land*.

3. Becauſe it diminiſhes the number of people: for as employment leſſens, the moſt induſtrious, rather than ſtarve here, will fly to other countries, where trade can maintain them. So the conſumption of theſe being taken away, the demand at market muſt grow leſs, and of courſe rents muſt fall, yet the farmer's charges muſt grow greater; for the fewer the hands, the higher wages are; this muſt break him in the end, and produce all the conſequences following that misfortune; beſides men who trade, bring in money; therefore the fewer they are, the leſs money will be brought; and the leſs money, the leſs rent can be given for *land*.

4. Becauſe the decline of trade diminiſhes *our riches*. This is a conſequence of the above remarks; for having fewer goods capable of being exported by reaſon of their dear price, and our manufactures declining, muſt in time be loſt: therefore the importation of foreign goods, muſt naturally increaſe, and more money go out to pay for them.

Nations that have no mines of gold and ſilver, have no means to get them but by foreign trade; and according to the quantity of theſe metals they poſſeſs, the price of their commodities, and therewith the value of their lands riſe and fall in proportion, which ſhall now be proved.

According to Dr. Davenant, the whole rental of England, in 1600, did not exceed ſix millions per annum, and the price of *land* was twelve years purchaſe: in 1688 the rental was fourteen millions, and the price of *land* was eighteen years purchaſe; ſo that, within this period, the *landed* intereſt roſe from ſeventy-two to two hundred and fifty-two millions: and this advance was owing to an increaſe of trade.

The Britannia Langens. page 12, ſays, if there were but five hundred pounds in England, an ox could hardly be worth a penny: therefore the rent muſt bear its proportion to the riches. This appears by Maitland's Hiſtory of London; for he ſays that, in the year 961, *land* ſold at one ſhilling per acre. The reaſon that land then bore ſo low a price, was, the low price the produce ſold at; for he ſays, that, in the year 1000, an ox ſold for 2*s.* 6*d.* a cow for 2*s.* a ſheep for 12*d.* and a ſwine for 8*d.*

In 1445, wheat was at 4*s.* 6*d.* per quarter; in 1447 at

8*s.*

8s.; in 1448 at 6s. 8d.; in 1449, at 5s. A bullock, in 1445, was 5s. a sheep 9l. 5⅝d: a hog, 1s. 11½d: clothing for a year at the same period, of a common servant of husbandry 3s. 4d.; of a chief carter and shepherd, 4s.; of a bailiff of husbandry, 5s. In 1512 the mean price of wheat in Yorkshire was 6s. 2d.; the price of malt was 4s. and of oats 2s.: So that the nominal price of grain at this time was about a seventh of its nominal price for the last twenty years. The price of a fat ox at the same time and in the same county was 13s. 4d.; of a lean ox, 8s.; of a weather 1s. 8d.; of a calf, 1s. 8d. of a hog, 2s: so that the nominal price of meat was no more than about a fifteenth of its present price, and bore the same proportion to the price of corn that it would now bear, were it at half its present price. In an act of parliament of the 25th of Henry VIII. beef, veal, pork, and mutton, are mentioned as the food of the poor, and their price limited to about a halfpenny a pound. Beef and pork in particular were sold in London at 2½ lb. and 3lb. for a penny; at the same time that wheat was at 7s. and 8s. a quarter, and bore the same proportion to the price of flesh as it would bear now, were it about 4l. a quarter. In 1549, wheat was in London 12s. per quarter; malt 10s.; barley 9s.; rye 6s. 8d.; oats 4s.; a middling ox 1l. 18s. a weather 3s. butter 2 and a penny a pound; and cheese a halfpenny a pound. See the citations in the Supplement to Price's Obs. on Reversionary Payments, &c. p. 385, &c. This could be only owing to the little foreign trade the nation had at these respective periods, and, consequently, to the little quantity of gold and silver which trade had then brought in.

But if it should be asked, what is the reason that, at present, all things are naturally so much advanced in price, to what they were in those days? the answer is, that the quantities of gold and silver brought to Europe since the progress made by the Spaniards and Portugueze in America, have made those metals more common, and of less value than formerly, so that 20s. will hardly purchase what 1s. would before the discovery of the West Indies. To which may be added the great increase of our national debt and taxes, together with the circulation of the interest of the principal money of the public funds, and likewise that great circulation of paper credit in trade, occasioned by notes and bills, which, by promoting an artificial circulation of property, raise the price of commodities, and give the appearance of wealth to the nation; though they are really the characteristics of a declining state. Poll. Dict. Com.

The dearness of commodities and the cheapness of money are the same things.

LANDGRAVE, formed of the German *land*, *earth*, and *graff*, or *grave*, *judge*, or *count*, a name formerly given to those who executed justice in behalf of the emperors, with regard to the internal policy of the country. The title does not seem to have been used before the eleventh century. These judges were first appointed within a certain district of Germany: in process of time the title became hereditary, and these judges assumed the sovereignty of the several districts or countries over which they presided. *Landgrave* is now applied by way of eminence to those sovereign princes of the empire who possess by inheritance certain estates called *landgravates*, and of which they receive the investiture of the emperor. There are four princes who have this title, viz. those of Thuringia, Hessia, Alsace, and Leuchtenberg. There are also other *landgraves* who are not princes, but counts of the empire. See COUNT.

LANDSKIP, or LANDSCHAPE, the view, or prospect, of a country, extended as far as the eye will reach.

LANDSKIP, in *Painting*, are pieces representing some champaign, or rural subject, as hills, vales, rivers, and country-houses, where human figures are only introduced as accidents, or circumstances.

Landskip painting is esteemed one of the lowest branches of PAINTING.

LANE, in the *Military Art*, is used when men are drawn up in two ranks facing one another. This is called *making a lane*, and is generally done in the streets through which a great person is to pass, as a mark of honour. But soldiers are often drawn up in this manner, when an offender is to run the gantlope. See *Military* EXECUTION.

LANGREL-SHOT, is a sort of shot sometimes used at sea, made of two bars of iron, with a joint, or shackle, in the middle; by which means it can be shortened, and so put the better into the gun; and at each end there is a half bullet, either of lead or iron.

This shot, when discharged, flies out expanded, and so does more execution among the enemies rigging, &c. It is never used in royal ships, but very often by privateers and merchantmen.

LANGUAGE, a set of words which any people have agreed upon, whereby to communicate their thoughts to each other.

The first principles of all *languages*, F. Buffier observes, may be reduced to expressions, signifying, first, the subject spoken of: secondly, the thing affirmed of it: thirdly, the circumstances of the one and the other. But as each *language* has its particular ways of denoting each of these, a *language* is only to be looked on as an assemblage of expressions, which chance or caprice has established among a certain people; just as we look on the mode of dressing, &c. Usage and custom are the rule of a *language*; and these hold their empire independent of reason, or any other cause: nor has reason any thing to do in *language*, unless to study or teach it such as it is. Here then commences grammar; a just plan of which supposes a *language* already introduced by use; and, without pretending to alter or amend a tittle, only furnishes reflections, called *rules*, to which the manners of speaking used in that *language* may be reduced; which assemblage of reflections is what we call the *grammar of that language*. This remark may obviate an abuse introduced among grammarians, who are ever crying out, "Usage is, in this point, opposite to grammar; or the "*language* here frees itself from the rules of grammar, "&c."

It is chance then to which we owe usage, and usage that makes the rules and measures of *language*. Usage, indeed, is somewhat dubious, and may be divided into *good* and *bad*. If it be asked, wherein the difference between these lies? it is in this; that the one is better established, or authorized, than the other: and if it be asked, wherein that difference of authority consists? it is answered, that in dead *languages*, that which makes the good usage is the writings of the best authors in that *language*: and if it be farther questioned, which are the best? those are allowed such, who wrote when the state was in its greatest glory. Thus the age of Augustus, being the most distinguished by great men, who then flourished, we call that *good Latin* which is conformable to the manners of speaking used by authors who wrote within fifty years before, and fifty after, the reign of that emperor. As to living *languages*, the good usage, or mode, is that which obtains among the most eminent persons, whether as to quality and authority, or as to learning, and the reputation of writing well.

With this view it is, that M. Vaugelas defines usage of a *language*, the manner of speaking used by the soundest or best part of the court, conformably to the manner of writing among the best part of the authors of the time. But this definition, how judicious soever, may occasion infinite doubt, for which is to be deemed the best part of the court, and of the writers? each party, doubtless, thinks itself the best. F. Buffier, therefore, very justly, instead of the best part, substitutes the greatest part, which brings the matter nearer to a certainty: the most numerous part being something fixed and palpable; whereas the most sound part may be insensible, or arbitrary. There is found a constant resemblance between the genius or natural complexion of each people, and the *language* they speak. Thus the Greeks, a polite, but voluptuous nation, had a *language* perfectly suitable, full of delicacy and sweetness. The Romans, who seemed only born to command, had a *language* noble, nervous, and august; and their descendants, the Italians, are sunk into softness and effeminacy, which is as visible in their *language* as in their manners. The *language* of the Spaniards is full of that gravity, and haughtiness of air, which make the distinguishing character of that people. The French, who have great vivacity, have a *language* that runs extremely brisk and lively. And the English, who are naturally blunt, thoughtful, and of few words, have a *language* more concise and sententious, though far from being deficient in respect of copiousness. As *to the origin of speech* or *language*, learned writers have adopted different opinions. Diodorus Siculus, lib. i. and Vitruvius, Archit. lib. ii. cap. 2. imagined, that men at first lived like beasts in woods and caves, forming only strange and uncouth noises, until their wants caused them to associate together; and that upon becoming associated with one another, they came to correspond about things, first by signs, then to make names for them, and in time to frame and perfect a *language*; and that the *languages* of the world are different, because different companies of men associating together in various places would form different sounds or names for things, and thereby cause a different speech or *language*. But as this conjecture contradicts the Mosaic history, other writers have supposed that the primitive *language* was formed by God himself, and supernaturally communicated to Adam. Most of the Jews adopt this opinion; and some of them apprehend that this was done by acquainting him in general

neral with the roots and fundamental parts of the tongue only; but others imagine, that the Creator revealed to him the whole extent and propriety of the *language*, even the letters, points, and accents. Onkelos paraphrases the words, which we render, *man was made a living soul*, man was made a speaking animal. Some have carried this opinion so far as not only to think that Adam had a particular *language* as innate to him as a power of thinking or of reasoning, but that all his descendents have it too, and that they would of themselves speak this *language*. Plato, in Cratyl. p. 383. p. 425 ed. Serrani, seems to maintain, that the first *language* was of divine formation; for he supposes that the names of things had originally some natural connection or congruity with the things themselves, and that the first names must have been justly imposed, because they were imposed by the gods. But there is another opinion, which seems more reasonable in itself, and more consonant to the Mosaic history; viz. that speech was the immediate gift of God to the first man; not that God really inspired him with any distinct or primitive *language*, but that he made him sensible of the power with which he was endued, of forming articulate sounds, and the use he might make of them as signs of his ideas, and leaving the arbitrary imposition of them to Adam himself. This seems to be intimated Gen. ii. 19. So that speech was attained by gradual invention of arbitrary sounds, to denote first the most obvious things, and afterwards the less obvious, as they occurred. However, though it does not seem impossible, that mankind might of themselves, in process of time, form a perfect *language*; yet it is not easily conceivable that Adam could attain the use of speech so soon as is represented to us by Moses, without divine assistance. Shackford's Connect. vol. i. book ii. p. 111. See LETTERS.

There is an affinity between dialects of the same mother-tongue, but none between mother-tongues themselves, as being supposed of entirely different origin.

Grammarians and etymologists find many affinities between *languages*, and imagine many more. Hebrew being the reputed source of all others, there are few *languages* but what have been observed to bear a near affinity to it, not only the Greek, the Latin, the Runic, Saxon, Swedish, German, and Welch, but even the Chinese and the Lapponic. Vid. Thomass. Mech. Etud. Gram. lib. i. chap. 7. Pref. p. 107. It. lib. iii. chap. 9. seq. Rowl. Mon. Antiq. p. 275.

Besides the conformity between words of different *languages*, grammarians consider the affinity between words of the same *language* formed from each other, e. gr. adjectives from substantives, participles from verbs, &c. Hence the class of paronyms, or conjugates.

LANGUAGES, *the diversity of*, is generally allowed to have taken its rise from the confusion at the building of the tower of Babel. See CONFUSION *of tongues*, and DISPERSION *of mankind*.

As to *the point of antiquity and priority* among *languages*, that has been extremely controverted. Herodotus tells us, that in the dispute between the Egyptians and Phrygians about the antiquity of their *languages*, Psammetichus, king of Egypt, ordered two children to be brought up, with express prohibition not to have one word pronounced before them, but to leave nature to speak of herself; and the first word they spoke happened to be *becos*, which, in the Phrygian *language*, signifies *bread*. The Egyptians, however, were not convinced with this proof. The Arabs dispute the point of antiquity with the Hebrews; but the Jews, jealous, even to excess, of the honour of their nation, positively insist on it, that the Hebrew tongue, such as it is found in the Holy Scriptures, is the primitive *language*, and that spoken by the first man.

Several Christian writers, as Chrysostom, Austin, Origen, and Jerom, among the ancients; and among the moderns, Bochart, Heidegger, Selden, and Buxtorf, agree with the Jews in maintaining the antiquity of the Hebrew *language*. Some have urged the great simplicity of this *language*, when traced to what was probably its original form; alleging, that it comprizes few names and radical words, and that its words, stripped of their appendages, are monosyllables. Thus, says Dr. Sharpe, it is very remarkable, if not peculiar to the Hebrew, that scarce any theme or root exceeds three letters; which, producing eleven thousand one hundred and fifty-four primitives, are the most natural and proper number of letters. Hence it seems to follow, that the Hebrew, and such other *languages* as abound with primitive words, not exceeding three letters in each, approach nearest to, or have the most of original *language*. Origin of Languages, &c. p. 14.

But the chief argument is taken from the names of persons mentioned before the confusion of Babel, which, it is said, are plainly of Hebrew derivation, and bear a just relation to the words from which they are derived: as אדם, *Adam*, from אדמה, *adamah, the ground*, because God formed him out of the earth; חוה, *Eve* or *Havah*, from חיה, *vivit*, because she was the mother of all living; קין, *Cain*, from קנה, *acquisivit*, because his mother obtained him from the Lord, &c. But the etymology of these names is lost, if they are taken in any other language besides the original one in which they were given. Nevertheless Grotius, in Gen. xi. 1. & Not. ad lib. i. De Verit. Rel. Christ. and others, have replied, that we have no certainty that the names used by Moses were the original names, and not translated by him from the primitive tongue into the Hebrew, or at least altered, in order to accommodate what he wrote to the understandings of the Jews. Thus we find, in fact, that he altered his own name, which was *Mouse*, of Egyptian original, and composed of two Coptic or old Egyptian words, *mose, water*, and *se, to preserve*, into משה, from משה, *to draw out*.

Besides, if the names given by Moses were the true original names, some of them might accidentally admit of a Hebrew derivation; several of them are more pertinently derived from some other of the oriental tongues than from the Hebrew, as Abel from the Syriac יהב איל, *ihab oi*, q. d. *Deus dedit*, and Babel from the Syriac *balbel, to confound*. Moreover, etymological allusions may be accidental; and some of those mentioned by Moses may be deduced from other tongues as well as the Hebrew. Thus, the Latin name for man, *homo*, is derived from *humus*, the ground. Le Clerc further advances, that several of these names were not the proper names, by which the persons were called from their birth, but cognomina or surnames, which were given to them afterwards, on account of something remarkable in their lives.

Of all the oriental *languages*, except the Hebrew, the Syriac has had the greatest number of advocates, especially among the eastern authors. They have alleged, that a dialect of this *language* was spoken in Mesopotamia, Chaldæa, and Assyria, where mankind first settled after the flood, and where, it is presumed, the *language* of Noah and his sons remained: to which argument they add, that the names of persons and places mentioned by Moses, are easily derived from that *language*. Besides those kindred *languages*, which are commonly called the oriental tongues, the Armenian, the Celtic, and the COPHTIC, pleading the antiquity of their nations, and the Armenians, that the ark first rested in their country, the GREEK, on account of its great extent and copiousness, the TEUTONIC, from which some have pretended to derive even the Hebrew itself, and the CHINESE, have aspired to preference, in point of antiquity.

The pretensions of the Chinese in particular have been supported not only from the great antiquity of that nation, their early acquaintance with arts and sciences, and their having preserved themselves so many ages from any considerable mixture or intercourse with other nations; but also from the singularity of the tongue itself, which consists of few words, all monosyllables, and is most simple in its construction, having no variety of declensions, conjugations, or grammatical rules. Besides, it is urged, that the Chinese are the posterity of Noah, and that Fohi, the first king of China, was Noah.

Mr. Webb, an ingenious writer in the reign of Charles II. strenuously maintains, that this is the only original *language*, and that they now talk in China the *language* of Paradise.

Others maintain, that the *language* spoken by Adam is lost; and that the Hebrew, Chaldee, and Arabic, are only dialects of the original tongue. So far are they from giving the priority to the Hebrew, that they maintain Abraham spoke Chaldee before he passed the Euphrates; and that he first learned the Hebrew in the land of Canaan; so that this was not a special *language* consecrated to the people of God, but was originally the *language* of the Canaanites.

M. Le Clerc is of opinion, the Hebrew is far inferior to the Greek both in copiousness, elegance, and perspicuity; it is dry, and destitute of ornaments, insomuch that, wanting expressions to vary the phrase, the same periods are perpetually returning. The rabbins, converting its poverty into an excellence, say, it is so pure and chaste, that it has no proper names for the parts of generation, nor for those by which the excrements are discharged. See HEBREW.

The Arabic is held the most copious of all *languages*. See the Preliminary Discourse to Sale's Koran.

LANGUAGES are in general divided into *original* or *mother-tongues*; as the HEBREW and ARABIC, in the East; the TEUTONIC and SCLAVONIC, in the West.

LANGUAGES, *secondary*, or *derivative*, which are those formed

formed out of a mixture of ſeveral others, as Latin, French, &c.

Kircher will have the COPHTIC a mother tongue, independent of all others.

Du Jon maintains the GOTHIC a primitive *language*, and the mother of all the Teutonic tongues; that is, of all thoſe ſpoken in the North.

Some add the Baſque, or Biſcayan, and Bas Briton, to the number of mother tongues, imagining them to have been thoſe of the ancient Celtæ, or Gauls.

LANGUAGES, *learned*, or *dead*, are thoſe which only ſubſiſt in books, and which muſt be learned by the rules of grammar; as the GREEK, HEBREW, SYRIAC, and CHALDEE.

Raimond Lully ſolicited the eſtabliſhment of the ſtudy of the learned *languages* a long time, in the thirteenth and fourteenth centuries. At length, in the year 1312, pope Clement, and the council of Vienne, appointed, that in the court of Rome, and in the univerſities of Paris, Oxford, Bologna, and Salamanca, there ſhould be inſtituted profeſſors of each, who ſhould have ſalaries from the reſpective courts. The monks, however, vigorouſly oppoſed the ſpreading of theſe ſtudies; and with ſo much ſucceſs, that Eraſmus tells us, in his time, *Græce noſſe ſuſpectum, Hebraice prope hæreticum.*

LANGUAGES, *living*, are thoſe ſtill ſpoken in ſome country or other; and which may be learned by converſation. The moſt popular among theſe are the FRENCH, ITALIAN, SPANISH, and ENGLISH.

The Spaniards ſeem to place the nobleneſs and gravity of their *language* in the number of ſyllables, and the ſwelling of words; and ſpeak leſs to be underſtood, than to be admired. Their terms are ſonorous; their expreſſions haughty; pomp and oſtentation run through all they ſay; their *language* cannot paint a thought to the life; it always magnifies it; frequently diſtorts it; and does nothing, if it do not exceed nature.

The Italian tongue does not ſwell up things to that degree, but it adorns and embelliſhes them more; yet theſe ornaments and embelliſhments are not real beauties. The Italian expreſſions, thus rich and brilliant, are like thoſe faces covered with patch and paint, which make a fine ſhew; but the finery is all deceit.

The French *language* (as ſome of their authors expreſs themſelves) is ſimple, without loweneſs; bold, without indecency; elegant and florid, without affectation; harmonious, without ſwelling; majeſtic, without pride; delicate, without ſoftneſs; and ſtrong, without roughneſs. Though, as to the points of ſtrength and majeſty, the French muſt give way to the Engliſh; which in theſe, as well as in copiouſneſs, exceeds moſt of the living *languages*; as far as it is inferior to ſome of them in ſmoothneſs and delicacy.

Of all the modern *languages*, the French is generally allowed to be the moſt clear, and fit for philoſophical and critical ſubjects; the chaſteſt and moſt reſerved in its diction; the moſt judicious and ſevere in its ornaments. Of all others, the Engliſh is ſaid to be the moſt honeſt, open, and undeſigning. With all its ſublimity, it is gay and pleaſant on occaſion; but its gaiety is ſtill moderated and reſtrained by good ſenſe; it hates exceſſive ornaments; and, for the greater ſimplicity, would almoſt chooſe, as ſome ſay of the French, to go naked; it never dreſſes more than decorum and neceſſity require.

The Engliſh *language* is derived from ſo many and ſuch different ſources, that, on this account, it is deficient in regularity and analogy. Yet we have this advantage to compenſate the defect, that what we want in elegance, we gain in copiouſneſs, in which laſt reſpect few *languages* will be found ſuperior to our own.

Ennius and Cecropa are celebrated for their knowledge of many *languages*. Mithridates, king of Pontus, it is ſaid, underſtood twenty-two tongues, which was the number of different people over whom he commanded; and thoſe *languages* he knew ſo well, that he was able to harangue each of his people in their own tongue. It was a ſaying of Charles the fifth, "That ſo many *languages* as a man underſtands, ſo many times he is man." Sultan Soliman's interpreter ſpoke perfectly well ſeventeen different *languages*. But among the moderns, none has been more remarkable in this way than Poſſelius; who, beſides a perfect knowledge of all the dead *languages*, was ſo well acquainted with the living, that it is ſaid he could have made the tour of the globe, without the uſe of an interpreter.

Bibliander has written of the analogy and proportion of *languages* and letters, De Ratione Communi Linguarum, in 1548. Geſner, of the Difference of *Languages*, in 1572. Lazius publiſhed an Introduction to the Learning of the politer *Languages*, in a common Method, in 1548. Megiſſer, a ſcheme of forty different *languages*, and different dialects, ſpecimens of each whereof he gives in the Lord's prayer, in 1593. De Recoles, in his Addition to the World of Daviti, has publiſhed the Pater-noſter in all the *languages* ſpoken among Chriſtians; and Mr. Chamberlayne has propoſed to do the ſame in a hundred *languages*, a ſpecimen of which has been already publiſhed. Albericus Gentilis wrote of the mixture of *languages*, in 1633. And father Reignier's Diſcourſe on Etymologies, is a work of the ſame kind. In 1613, Duret publiſhed a treaſure of the hiſtory of all the *languages* in the univerſe. Guichart has a treatiſe of the etymological harmony of *languages*, publiſhed in 1610. Brerewood has given us curious enquiries into the diverſities of *languages* and religions, publiſhed in 1635.

LANGUAGE, *philoſophical*. See CHARACTERS, *univerſal*.

LANGUAGE is alſo uſed, in the order of Malta, for *nation*. The knights of Malta are divided into eight *languages*; three whereof are for France; viz. the *language* of Provence, of Auvergne, and of France; two for Spain, thoſe of Caſtile and Arragon; the other three are the *languages* of Italy, England, and Germany.

Each of theſe *languages* has its chief, who preſides in aſſemblies of the *language* to which he belongs. See MALTA.

LANGUAGE, *Frank*. See FRANK.

LANGUAGE, *Helleniſtic*. See HELLENISTIC.

LANGUED, *langue*, in *Heraldry*, is applied to ſuch animals whoſe tongues appear out of their mouths; being of a colour different from that of the body of the animal.

LANGUENTE, in the *Italian Muſic*, is uſed to denote a languiſhing and ſoft manner of ſinging.

LANGUOR, in *Medicine*, ſignifies a *faintneſs*, or relaxation of the members, ariſing either from a want or decay of ſpirits, through indigeſtion, or too much exerciſe; or from an additional weight of fluids, cauſed by a diminution of the excretion by the common diſcharges.

LANIARDS. See LANIERS.

LANIGEROUS, any thing that bears WOOL. Hence,

LANIGEROUS, or LANUGINOUS *trees*, among *Herbaliſts*, are thoſe trees that bear a woolly downy ſubſtance; as, the black, white, and trembling poplars, oſiers, and willows of all ſorts.

LANIS *de vexſantia Wallie tradueendis abſque cuſtuma*, &c. an ancient writ that lies to the cuſtomer of a port, to permit one to paſs wool without paying cuſtom, he having paid it before in Wales.

LANISTA, in *Antiquity*, is ſometimes uſed to ſignify an *executioner*, but more frequently for a maſter-gladiator, who taught the uſe of arms, and had always people under them, ready to exhibit ſhews of that kind. For which purpoſe they either purchaſed gladiators, or educated children, that had been expoſed, in that art.

LANISTA was alſo uſed to denote one who taught game-cocks to fight.

LANIUS. See BUTCHER *Bird* and FLUSHER.

LANNARIUS, in *Ornithology*, the name of a bird of the long-winged hawk kind; the *falco lanarius* of Linnæus, called in Engliſh the *lanner*, and the male the *lannaret*. Its beak and legs are blue, and its head and neck variegated with large ſtreaks of black and white; its back, wings, and tail, are not varhegated, unleſs with a few ſmall white ſpots; and its wings, when extended, are ſeen ſpeckled underneath with ſmall round white ſpots; its neck is very ſhort, as are alſo its legs. It is common in France, and abides the whole year there, and is very docile, and ſerves to all the purpoſes of hawking. In Italy the ſpecies ſeems ſomething different, having much of a yellowiſh brown about the ſhoulders, and being indocile and of no uſe in ſporting. Ray. See HAWK. This ſpecies breeds in Ireland, and is thus deſcribed by Mr. Pennant: it is leſs than the buzzard; the [illegible] a pale greeniſh blue; the crown of the head [illegible] and yellow clay colour; above each eye [illegible] of the head paſſes a broad white line [illegible] a black mark pointing down; the [illegible] breaſt tinged with dull yellow, and marked with [illegible] ſpots pointing downwards; the thighs [illegible] in the ſame manner; the back and covers of the [illegible] deep brown, edged with a pale; quills [illegible] the inner webs marked with oval [illegible] and the tail ſpotted like the wings. Brit. *Zool.* [illegible] p. 182.

LANNIERS, or LANIARDS, in a *Ship*, are ſmall ropes reeved into the dead-men's eyes of all the ſhrouds and chains. Their uſe is to ſtiffen, or ſet taught the ſhrouds. The ſtays alſo of all maſts are ſet taught by lanniers. That rope, which faſtens the ſlopper of the halliards to them, is called alſo a *lannier*: and the term is generally applied to any ſhort piece of cord or line, faſtened to ſeveral machines in a ſhip, and ſerving to ſecure them in a particular place, or to manage them more conveniently.

ly; such are the *laniards* of the gun-ports, the *laniard* of the buoy, of the cat-hook, &c.

LANSPESSADE, in *Military Affairs*. See ANSPESSADE.

LANSQUENET is the name of a game at cards.

LANTANA, in *Botany*, the *American viburnum*, a genus of the *didynamia angiospermia* class. Its characters are these: the empalement of the flower is cut into four segments; the flower is of an irregular shape, having a cylindrical tobe spread open at the bottom, where it is divided into five parts; in the centre is situated the germen, attended by four stamina, two being longer than the other; the germen changes to a roundish fruit, opening into two cells, inclosing a roundish seed. There are nine species.

LANTER-LOO, or LOO, is the name of a common game at cards.

LANTERN, or LANTHORN, a cover for a luminary, made of some transparent matter; serving to transmit the light, and, at the same time, to screen it from the wind and rain.

The word is derived from the French *lanterne*; and that from the Latin *laterna*, of *lateo, I am hidden*; *eo quod lucem habeat interius absconsam*, because the light is hidden within, say Isidore and Lambin. But, according to Pezron, *laterna* comes from the Celtic *latern*; and according to Salmasius, *lantern* comes from *lata*, of *fero*, because it bears a lamp, or a light.

Epictetus's *lantern* is said to have been sold for three thousand drachms; that of Diogenes was held in great veneration among the ancients; and that of Judas is still preserved in the treasury of St. Denys, as a very curious piece of antiquity.

Lanterns are made of glass, horn, paper, &c. Formerly they were made of the horn of a wild bull, called *urus*; which, when cut into thin laminæ, Pliny tells us, was very transparent. Those of horn were first introduced into England by king Alfred, about the year 887, in order to preserve his candle time-measurers from the wind. See LENS. And. Hist. Com. vol. i. p. 45.

LANTERN, *dark*, is a *lantern* with only one opening or light, which, too, may be closed up, when the light is to be entirely hid; and may be presented to the person one would see, without being perceived one's self.

The ancients had their dark *lanterns*, but they differed from our's: they were covered with four skins, one on each side, or light, three whereof were black, and only the fourth transparent. Casaubon, who gives us the description, took it from a manuscript of Julius Frontinus. These were principally used in their armies, when they were to march privately off from their enemies in the night time.

LANTERNS are used at sieges in the night-time, upon the batteries; but these must be blind or dark *lanterns*. There is always great provision of them in all store-houses.

Lanterns are also used in a ship, particularly for the purpose of directing the course of other ships in a fleet or convoy; such are the poop and top-*lanterns*, &c.

LANTERNS, *feast of*, in China, is a celebrated feast held on the fifteenth day of the first month; and is so called from the great number of *lanterns* hung out of the houses, and in the streets; insomuch that it rather appears a fit of madness, than of feasting. On this day are exposed *lanterns* of all prices, whereof some are said to cost two thousand crowns. Some of their grandees retrench somewhat every day out of their table, out of their dress, equipage, &c. to appear the more magnificent in *lanterns*. They are adorned with gilding, sculpture, painting, japanning, &c. and as to their size, it is extravagant; some are from twenty five to thirty feet diameter; they represent halls and chambers; and two or three such machines together would make handsome houses: so that in China they are able to eat, lodge, receive visits, have balls, and act plays, in a *lantern*.

To illumine them, they should have bonfires; but as that would be inconvenient, they content themselves with lighting up in them a great number of torches or lamps which at a distance have a beautiful effect. In these they exhibit various kinds of shews to divert the people.

Besides these enormous *lanterns*, there is a multitude of other smaller: these usually consist of six faces or lights, each about four feet high, and one and a half broad, framed in wood finely gilt and adorned; over these they stretch a fine transparent silk, curiously painted with flowers, trees, and sometimes human figures: the painting is very extraordinary, and the colours extremely bright; and when the torches are lighted, they appear highly beautiful and surprising.

LANTERN, in *Architecture*, denotes a kind of little DOME raised over a large one, or over the roof of a building, to give light, and to serve for an acroter to finish the building.

LANTERN is also used for a square cage of timber, with glass in it, placed over the ridge of a corridor, or a gallery between two rows of steps to illuminate them.

LANTERN, *magic*, in *Optics*, the name of a machine, which, in the dark, represents various images and spectres on a wall, or other white surface, so odd and surprising, that those who are not in the secret, think them the effect of MAGIC.

LANTERN-*fish*, the English name of a fish of the soal-kind, but smaller, and smoother to the touch, called in Latin *ammoglossus*.

LANTERN-*fly*, in *Natural History*, the name of a very singular kind of insect produced in the West Indies, and carrying a strong light with it in the night. The structure of the trunk in this insect is of the same kind with that of the cicada; and as it wants the power of making the noise for which the cicada is so famous, it belongs, according to Mr. Reaumur's distinctions, to that species of insect called the *procigale*, or *pseudocada*.

The glow-worm, and the luminous beetles, with all the other luminous insects we are acquainted with in this part of the world, diffuse their light from a part which is near the extremity of the body, and under the belly, but the *lantern-fly* gives it from its head. It differs also greatly in the degree of light; for this, in all the insects we are acquainted with, is very feeble; whereas, in this fly it is so strong, that Mrs. Merian, who is the first that well described it, says she could read a small print in a dark night by the light that one of them gave. The head of this creature, strictly speaking, is very short, not exceeding the length of one of the rings of the body, if it be measured from its joining with the corcelet to its joining with the *lantern*; but if that part be accounted a portion of the head, then the head is equal in length to the whole body. This *lantern* is wider than it is deep, or thick, and has near its origin a large protuberance, which gives it a bunched or humped look. There are several tubercles and lines on it of a reddish colour. The ground colour is an olive-brown, and underneath it has one large rib running all the way along it, from end to end, and dividing it into two, and by the sides of that there are some others. These are all reddish, and those nearest the edges have small rows of spines running along them. Over each of the eyes there is a round granulated prominence, which seems to have been a collection of smaller eyes; and if so, the animal is supplied with the organs of vision in a different manner from all other known creatures. But there requires an examination of the creature on the spot, and while alive, in order to find out this. The upper pair of wings are not perfectly transparent, they are dotted with white in some places, and are variegated near their origin with several blackish spots. The under pair are more transparent than the upper; they are much shorter, and are broader than the others: these have each a large and beautiful round spot near the extremity, resembling that on the wing of the peacock-butterfly. The colours of the circles of these eyes are brown and olive; the last colour very bright and clear, the other very dusky and obscure. The spots are so large, that they appear very beautiful. Reaumur, Hist. Inf. vol. ix. p. 247.

LANTERNISTS, a name assumed by the academicians of Thoulouse.

LANUGINOUS. See LANIGEROUS.

LANUGO, in *Botany*, *down*; that soft, hairy, or woolly covering, which grows on the leaves, stalks, or fruit, of divers plants.

Such is that found on the leaves of the rose-campion, and on the fruit of the peach-tree.

LANYARDS on *ship-board*. See LANIERS.

LAOCOON, in the *History of the Arts*, is a celebrated monument of Greek sculpture, executed in marble by Polydorus, Athenodorus and Agesander, the three famous artists of Rhodes. This remain of antiquity was found at Rome in the ruins of the palace of Titus, in the beginning of the sixteenth century, under the pontificate of Julius II. and since depositied in the Farnese palace. *Laocoon*, the priest of Apollo and Neptune, is here represented with his two sons, with two hideous serpents clinging round his body, gnawing it, and infecting their poison. Virgil has given us the following description of the fact:

Serpens amplexus uterque
Implicat & miseros morsu depascitur artus:
Corripuit, spirisque ligat ingentibus, & jam
Bis medium amplexi, bis collo squamea circum
Terga dati, superant capite, & cervicibus altis.

This statue exhibits the most astonishing dignity and tranquility of mind in the midst of the most excruciating torments: Pliny says of it, that is is, *opus omnibus picturæ & statuariæ artis præferendum*. Lib. xxxvi. c. 5.

LAPACTICS, from λαπαζω, *I evacuate*, a term used by the old writers in medicine to express such things as purged by stool, or at least gently loosened the belly. It was sometimes applied to the cathartic medicines, and sometimes to those foods which were of this tendency.

LAPARA, Λαπαρα, a word used by some writers to express the flanks, or that part which is situated on each side of the body, between the spurious ribs and the hips.

LAPATHUM, in *Botany*. See DOCK.

LAP-DOG, called also *melitæus* or *sfior*, and by Dr. Caius, in his System of British dogs, the spaniel gentle or comforter, is a species of the most generous kind of dogs. See DOG.

Mr. Pennant observes, that the Maltese little dogs were as much esteemed by the fine ladies of past times as those of Bologna are among the moderns. Old Hollingshed is ridiculously severe on the fair of his days for their excessive passion for these little animals; which is sufficient to prove it was in his time, viz. in the reign of queen Elizabeth, a novelty.

LAPHIATI, in *Zoology*, the name by which the people of Lemnos call a species of serpent, supposed by Belonius to be the same with the ELAPS, or *elaphis* of the ancients.

LAPIDARY, *Lapidarius*, an artificer, who cuts precious stones.

The art of cutting precious stones is very ancient; but, like other arts, its original was very imperfect. The French have succeeded in it the best; and the *Lapidaries* of Paris, who have been a corporation since the year 1290, have carried it, especially the cutting of diamonds called *brilliants*, to a very great perfection, but not superior to that of the English.

There are various machines used in the cutting of precious stones, according to the quality of the matter to be cut: the diamond, which is extremely hard, is cut and formed on a wheel of soft steel, turned by a kind of mill, with diamond dust tempered in oil of olives; and this serves to polish them as well as to cut them.

Oriental rubies, sapphires, and topazes, are cut and formed on a copper wheel, with oil of olives, and diamond dust: they are afterwards polished on another copper wheel with tripoli and water.

Emeralds, hyacinths, amethysts, garnets, agats, and other stones less hard, are cut on a leaden wheel, with smalt and water, and polished on a tin wheel with tripoli.

Turquois, of the old and new rock, lapis girasol, and opal, are cut and polished on a wooden wheel with tripoli.

LAPIDARY is also used for a virtuoso skilled in the nature, kinds, &c. of precious stones; or a merchant who deals in them.

LAPIDARY *style*, denotes the style proper for monumental or other inscriptions.

This is a kind of medium between prose and verse; the jejune and the brilliant are here equally to be avoided. Cicero has prescribed the rules of it: *Accedat oportet oratio purior, verborum, plena spiritus. Omnium sententiarum gravitate, omnium verborum ponderibus, est utendum.*

The *lapidary style*, which was lost with the ancient monuments, has been retrieved, at the beginning of this age, by count Emanuel Tesoro: it is now used various ways at the beginning of books; and even epistles dedicatory are composed in it, of which we have no example among the ancients.

LAPIDESCENT, any thing which has the faculty of petrifying, or turning bodies to a stony nature.

Naturalists speak of a *lapidescent* principle, a *lapidescent* spirit, a *lapidescent* juice, &c.

LAPIDESCENT *waters*, or *springs*, are such as, having stony particles dissolved and swimming in them, do deposit the same on wood, leaves, and other bodies immerged therein; which, being incrusted herewith, are commonly mistaken for petrifactions.

LAPIDIFICATION, in *Chemistry*, an operation whereby any substance is converted into a sort of stone.

This is done by dissolving a metal, for instance, in a corrosive spirit, or menstruum; and afterwards reducing that dissolution into the consistence of a stone.

Lapidification is practised in metals, fixed salts, and salts of plants.

The term is also used for the making of artificial stones.

LAPIS, in the general sense. See STONE.

LAPIS *Arabicus*, in the *Natural History of the Ancients*, the name of a stone of a fine white colour, resembling the purest ivory; and which, though naturally of a firm, solid, and compact texture, yet, when burnt, became light, porous, and spongy, and assumed the figure and appearance of a pumice; and was used like it in the compositions of the ancient physicians for cleaning the teeth.

LAPIS *arsefsi*, in *Natural History*, a name given to several sorts of stones, and other fossils, which had lain in the neighbourhood of copper-mines, and been impregnated with particles of copper, though not in a sufficient degree, to be thought worthy the name of *copper-ores*. See PYRITES.

The same sort of stones were also sometimes called *chalcites*, which made some confusion, as it gave occasion to confound them with the true chalcitis.

LAPIS *asbestos*. See ASBESTOS.

LAPIS *aëtites*. See ÆTITES.

LAPIS *Armenus*. See ARMENIAN *Stone*.

LAPIS *Assius*, in the *Natural History of the Ancients*, the name of a stone, called also sarcophagus, from its power of consuming flesh.

It was a stone much used among the Greeks in their sepultures, and is recorded to have always perfectly consumed the flesh of human bodies, buried in it, in forty days. This property it was much famed for, and all the ancient naturalists mention it. There was another very singular quality also in it, but whether in all, or only in some peculiar pieces of it, is not known; that is, its turning into stone any thing that was put into vessels made of it. This is recorded only by Mutianus and Theophrastus, except that Pliny has copied it from these authors; and some of the later writers on these subjects from him.

This effect might probably be a kind of incrustation, formed on substances inclosed in vessels made of this stone, by water passing through its pores, dislodging from the common mass of the stone and carrying with it particles of such spar as it contained; and afterwards falling in repeated drops on whatever lay in its way, it might again deposit them on such substances, in form of incrustations.

The place from whence the ancients tell us they had this stone was Assos, a city in Lycia, in the neighbourhood of which it was dug: and De Boot informs us, that in that country, and in some parts of the East, there are also stones of this kind, which if tied to the bodies of living persons, would in the same manner consume their flesh. Hill's Notes on Theophrastus, p. 14.

LAPIS *atramentarius*, the *copper-stone*. See PYRITES.

LAPIS *bezoardicus*. See BEZOAR.

LAPIS *Bononiensis*, the *Bolonian stone*, a peculiar species of stone found in Bologna. See BOLONIAN *stone*.

The whole art of preparing this stone, so as to make it shine in the dark, is described at large in Hook's Philosophical Collections, by sir Marc Antonio Cellio, and in a book of the same author, published at Rome in 1680, expressly on that subject.

The *stone* is found most easily after rain; when the earth being washed away, the several masses of it appear as bright as burnished silver, or with the glittering of talc, resembling the gloss of a looking-glass. It Fosforo de Marc Anton Cellio.

The *stone* is of no certain figure, but is sometimes round, sometimes oblong and cylindric, sometimes lenticular; the last kind usually proves the best of all, as being more shining and transparent. They are usually as big as an orange, and sometimes are found of five pounds weight, and are very light, considering their bulk. They are of various colours; some are ash-coloured, some of a sky-blue, some of a ferruginous colour, others yellow, others greyish white, and some almost perfectly white. The best for use are the sky-coloured and the white. When this *stone* is prepared, it affords an efflorescence, in which lies its principal virtue of receiving light; which it does either from the sun, the moon, the common day-light, or a flame, but in different degrees. When carried into the dark, it appears exactly like a burning coal, and the light it gives is sufficient to read by, if the letters be placed near the *stone*. It does not retain its light long, but requires often renewing; and when well prepared, its virtues will last five or six years, but seldom longer.

The way of seeing it to the greatest advantage, is after the eye has been kept for some time in a dark room, and the stone is brought in there immediately from being held in the sun.

The best method of preparing it is this: make a cylindric furnace of iron or copper-plates, seven inches in diameter, and as many in height. Line the inside of it with a strong lute; so that the inside may be six inches wide in the clear hollow; at the top of this there are to be made four notches of 2½ inches deep, and 1½ inch wide; to this make such a cylindrical part of the same diameter, but a little higher, and make at the bottom two ash-holes, or air-holes, big enough to put in one's hand. Line this, as the other, with good lute, and give it a bottom of lute, that it may the more strongly reflect the heat; and make a cover for the top, lining it in the same manner with the lute: into this furnace put an iron-wire grate near the bottom, to sustain the coals, and freely

admit the air. On this grate lay ſome pieces of lighted charcoal, and on theſe put others not lighted, all broken to the ſize of a walnut, or thereabouts. Some of the ſtones muſt be powdered, and thoſe which are to be calcined muſt be dipped in ſtrong aqua vitæ, and while wet rolled in this powder, or the powder itſelf may be made up into thin cakes with mucilage of gum tragacanth. Theſe ſtones, thus covered, or the cakes, muſt be laid upon the bed of charcoal cloſe to one another, and another bed of charcoal, in the like ſmall pieces, muſt be laid over them up to the top of the furnace: the cover of the furnace is then to be put on, and the fire lighted. When the charcoal is all burnt away, and the whole is cold, take out the ſtones, and taking out the cruſt from them, wrap them up in ſilk or cotton, and keep them in a cloſe box for uſe.

The cruſt which is taken off from the ſtones is to be preſerved; it ſhines as well as the ſtone, and is to be beat to powder, and rubbed over any thing that is to be made to ſhine; the thing being firſt daubed over with the white of an egg: This will make it ſtick on, and the whole will ſhine like the ſtone.

The furnace here deſcribed is not abſolutely neceſſary to the ſucceſs of the operation; but it is convenient to know the quantity of charcoal neceſſary to give the ſhining quality to the ſtone, ſince an exceſs of heat deſtroys it, and too ſmall a degree is not ſufficient to raiſe it. See LIGHT and PHOSPHORUS.

LAPIS *calaminaris*. See CALAMINARIS *lapis*.

LAPIS *calcarius*. See LIME.

LAPIS *cancer cancri*, in *Natural Hiſtory*, a name given by Geſner, and ſome other writers, to the foſſile ſhells, ſince called *tubuli marini concamerati*, and by ſome *polythalamia* and *scitha-ceratiæ*. See TUBULI *concamerati*.

LAPIS *ceratites*. See UNICORNU *foſſile*.

LAPIS *chius*. See CHIA-*ſtone*.

LAPIS *corneus*, *horn-ſtone*, a name given by many of the German authors to flint, which ſome of them have alſo very improperly called *pyrites*, or the fire-ſtone, becauſe it is uſed to ſtrike fire with.

Buttner, in his Coralliographia Subterranea, has a remarkable ſyſtem in regard to flint. He is of opinion, that all flints are foſſile corals. But it is to be obſerved, that the reſemblance of flints and corals are but very ſlight and ſuperficial, and we have no proof from their internal ſtructure of their being at all alike.

LAPIS *dentalis*. See DENTALIS.

LAPIS *divinus*, a ſpecies of jaſper, ſo called from its imaginary virtues, as a diuretic and expeller of poiſon. It is found on the ſhores of the Ganges, and other parts of the Eaſt-Indies.

The Turks are extremely fond of it in their curious works, particularly for the handles of their ſabres. This is alſo called JADE and NEPHRITIC *ſtone*.

LAPIS *hæmatitis*. See HÆMATITIS.

LAPIS *hyænius*. See HYÆNIUS *lapis*.

LAPIS *Hybernicus*. See *Iriſh* SLATE.

LAPIS *infernalis*, a cauſtic ſtone prepared various ways: ſometimes of ſtrong ſoap-lees evaporated to a dryneſs, and the remainder kept in a glaſs well ſtopped from the air. Sometimes it is made of calcined vitriol, tartar, and ſal ammoniac, and boiled in quick-lime water to a ſtrong lixivium; then ſtrained, and evaporated till dry.

The lunar cauſtic, or *lapis infernalis*, is made by putting cryſtals of ſilver into a Heſſian crucible, and placing the crucible in a furnace, which ought to draw little air, and ſurrounded by a very ſmall quantity of lighted coals. The heat at firſt ſhould be moderate; and while the ebullition gradually diminiſhes, the fire is to be increaſed; and when the matter is brought to a perfect and tranquil fuſion, it is to be caſt in an iron mould, previouſly heated, and greaſed in its inner ſurface, where it is to be left till it is fixed and cold, and then put into a bottle with a glaſs ſtopper.

The lunar cauſtic ought to be formed into ſmall cylindrical pieces, like pencils, of about a line in diameter, and the ſurgeon who uſes them puts them in a crayon or pencil caſe, to prevent his fingers being injured by touching them. The mould, for this purpoſe, conſiſts of five or ſix hollow cylinders, placed vertically and parallel to each other, to which a gutter is adapted, by means of which the matter is poured into them. This mould is compoſed of two pieces, which exactly fit each other, in each of which the ſame number of hollow ſemi-cylinders correſpond to thoſe of the other; and, therefore, when the lunar cauſtic is caſt and cooled, it is obtained in entire cylinders, by ſeparating the two pieces of the mould. See CAUSTIC, *lunar*, and CRYSTALS *of ſilver*.

LAPIS *Iſlebianus*. See ISLEBIANUS *lapis*.

LAPIS *Judaicus*. See JUDAICUS.

LAPIS *lazuli*. See LAZULI.

LAPIS *lucis*, the *ſtone of light*, in the *Materia Medica of the Arabs*, a name given to the braſſy marcaſite or pyrites. The Arabians have adopted this. Avicenna ſuppoſes this ſubſtance to be called ſo, becauſe it was uſed, after calcination, for diſeaſes of the eyes. It is very probable, that where vitriolic medicines take place, the caput mortuum of this foſſil, which is only a colcothar of vitriol, may be of uſe. But its virtues in this reſpect can never be ſuppoſed ſo eminent, as to have intitled it to the pompous name it bears. It ſeems more probable, that it was called the *ſtone of light*, either from its glittering appearance where freſh broken, or from its giving large ſparks of fire, when ſtruck againſt a ſteel. It was from this quality that it obtained the name of *pyrites*, or fire-ſtone, it giving fire on the colliſion with ſteel much better than flint does.

LAPIS *luminis*, is uſed by ſome authors in the ſame ſenſe as *lapis lucis*, that is, for the pyrites.

LAPIS *Lydius*. See LYDIUS *lapis*.

LAPIS *marmoreus*, a marble ſtone about twelve foot long and three foot broad, placed at the upper end of Weſtminſter-hall: where was likewiſe a marble chair erected on the middle thereof, in which our kings anciently ſat at their coronation dinner, and at other times the lord chancellor. Over this marble table are now erected the courts of Chancery, and King's-bench. Orig. Juridical. 37.

LAPIS *melitites*. See MELITITES.

LAPIS *molybdinus*, or *French chalk*. See MOLOCHITIS.

LAPIS *medicamentoſus*, or the medicinal ſtone, is a compoſition of roch alum, litharge, colcothar of vitriol, Armenian bole, and vinegar, boiled to the conſiſtence of a hard ſtone. It is uſed to faſten the teeth, preſerve the gums, heal and dry up ulcers and wounds; and is uſed in injections, and in compoſitions for ſore eyes.

LAPIS *muſicalis*, the *muſic-ſtone*, in *Natural Hiſtory*, a name given by Mr Sivers to a ſtone found in Pruſſia, carrying naturally on it all the muſical characters found on the ſcale, commonly called the *muſic-ſhell*. He deſcribes the ſtone, which ſeems to have been a ſingle ſpecimen, and as this author is the only one who ever met with it, it is much to be ſuſpected that either fraud or fancy has had a great ſhare in the matter.

LAPIS *nephriticus*. See NEPHRITIC *ſtone*.

LAPIDES *picti*, in *Natural Hiſtory*, a term uſed by Langius, to expreſs ſuch ſtones as are found with the delineations of fiſhes, trees, and ſhells, as well as leaves of ferns and other plants, very perfectly repreſenting the things themſelves, but ſcarce at all ſtanding out above the ſurface of the ſtone, and having in themſelves ſcarce any thickneſs. It is very evident, that the bodies repreſented are not here, in reality, but the whole configuration is owing to the natural veins of the ſtone, and the coaleſcence of the ſeveral ſmaller maſſes of which each large ſtone is compoſed, and to the vapours from within the earth, getting into the natural fine cracks in the ſtones, and tinging their ſides with blackneſs.

LAPIS *ſpecularis*. See SPECULARIS.

LAPIS *thyites*. See THYITES.

LAPLYSIA, in *Natural Hiſtory*, a genus of the *molluſca* order of worms: the body is covered with reflex membranes; there is a ſhield-like membrane on the back, a lateral pore on the right ſide, for the genitals; the vent is on the extremity of the back, and it has four feelers, reſembling ears. There is only one ſpecies, which ſome have called the ſea-hare.

LAPPA, in *Botany*. See BURDOCK.

LAPPAGO, in *Botany*, a name given by the old Roman authors to the plant we call aparine, or cleavers, or ſome herb nearly allied to it.

LAPPULA, in *Botany*, a name given by ſome to the great cauſalis, or rough-fruited ſtone-parſley, or *baſtard* PARSLEY.

LAPSANA, in *Botany*. See NIPPLE-*wort*.

LAPSARII. See INFRALAPSARII, SUBLAPSARII, and SUPRALAPSARII.

LAPSE, a ſlip or omiſſion of a patron to preſent a clerk to a benefice within ſix months of its being void: in which caſe, the benefice is ſaid to be in *lapſe*, or *lapſed*, and the right of preſentation devolved to the ordinary.

And if the ordinary neglect to preſent during the ſame time, the right of preſentation accrues to the metropolitan, and to the king by neglect of the metropolitan. This right of *lapſe* was firſt eſtabliſhed in the reign of Henry II. when the biſhops firſt began to exerciſe univerſally the right of inſtitution to churches: and therefore, when there is no right of inſtitution, there is no right of *lapſe*; ſo that no donative can *lapſe* to the ordinary, unleſs it hath been augmented by the king's bounty; but no right of *lapſe* can accrue, when the original preſentation is in the crown. In caſe the benefice becomes void by death, or ceſſion through plurality of benefices, there the patron is bound to take notice of the vacancy at his own peril; but in caſe of a vacancy by reſignation, or canonical deprivation, or if a clerk pre-

sented be refused for insufficiency, these being matters of which the bishop alone is presumed to be cognizant, here the law requires him to give notice thereof to the patron; otherwise he can take no advantage by way of *lapse*. Neither shall any *lapse* accrue thereby to the metropolitan or the king. If the bishop refuse or neglect to examine and admit the patron's clerk, without good reason alleged or notice given, he shall have no title to present by *lapse*: and if the right of presentation be litigious or contested, and an action be brought against the bishop to try the title, no *lapse* shall occur till the question of right be decided. If the bishop be both patron and ordinary, he shall not have a double time allowed him to collate in: and if the bishop doth not collate his own clerk immediately to the living, and the patron presents, though after the six months are lapsed, yet the presentation is good, and the bishop is bound to institute the patron's clerk. If the bishop suffer the presentation to *lapse* to the metropolitan, the patron also has the same advantage if he presents before the archbishop has filled up the benefice: yet the ordinary cannot alter *lapse* to the metropolitan, collate his own clerk to the prejudice of the archbishop. But if the presentation *lapses* to the king, the patron shall never recover his right, till the king has satisfied his turn by presentation; for *nullum tempus occurrit regi*. Blackst. Com. vol. ii. p. 276, &c.

LAPSED *legacy*. See LEGACY.

LAP-SIDED, in *Sea-language*, denotes the state of a ship, which is built in such a manner as to have one side heavier than the other, and consequently to retain a constant heel, or tendency towards the heavier side, unless when she is brought upright by placing a greater quantity of the cargo or ballast on the other side.

LAPWING, *capella*, in *Ornithology*, the black-breasted *tringa*, with a hanging creft, or TRINGA *vanellus* of Linnæus, commonly known in England by the name of lapwing or bastard plover, and called by some, in Latin, *vanellus*. It is a very well-known bird, about the size of a pigeon, and has a beautiful creft upon its head. Its legs are long and red, and it is remarkable for running swiftly: the female is rather less than the male.

Were the *lapwing* less common, it would be highly esteemed for its beauty. It is very frequent in our fenny countries, and in the wet places of most other parts of Europe.

It lays four eggs, of an olive caft, ſpotted with black, in a ſlight neſt made with a few bents. The young as ſoon as hatched run like chickens, and are preſerved with great anxiety and clamour by their parents from apprehended danger; which are ſaid to flutter along the ground to a conſiderable diſtance from their neſt, to elude purſuers, and to become more clamorous when moſt remote from it. The eggs are much valued for their delicacy, and are ſold by the London poulterers for three ſhillings per dozen. In winter, *lapwings* join in large flocks and are very wild; their fleſh is very good, their food being inſects and worms. During October and November, they are taken in the fens in nets, in the ſame manner as ruffs are, but are not preſerved for fattening, being killed as ſoon as caught. Ray and Pennant.

LARIARIUS, a kind of athleta among the ancients, who in one hand held a *laqueus*, i. e. a ſort of ſnare, wherewith to embarraſs and entangle his antagoniſt, and in the other a poignard to ſtab him.

LAQUER. See LACQUER.

LAQUEUS, in *ſurgery*, a *noose* or *ſnare*; or a kind of ligature, ſo contrived, that when ſtretched, by any weight, or the like, it draws up cloſe.

Its uſe is to extend broken or diſjointed bones, to keep them in their places, when they are ſet, and to bind the parts cloſe together.

LAR-BOARD, the left-hand ſide of a ſhip, when you ſtand with your face toward the head.

LARCENY in *law*, is a theft of perſonal goods or chattels, in the owner's abſence. See THEFT.

The word comes from the French *larcin*; and that from the Latin *latrocinium*, *theft*.

Larceny is diſtinguiſhed by the law into two ſorts; the one called *ſimple larceny*, or plain theft unaccompanied with any other atrocious circumſtance; and *mixt* or *compound larceny*, which includes in it the aggravation of taking from one's houſe or perſon.

In reſpect of the thing ſtolen, ſimple *larceny*, is either *great* or *ſmall*.

LARCENY, *Great*, is when the things ſtolen, though ſeverally, exceed the value of 12 *d*.

LARCENY, *Petty*, is when the goods ſtolen exceed not the value of 12 *d*.

Simple larceny is defined the felonious taking, and carrying away, the perſonal goods of another: ſo that in order to conſtitute this crime, there muſt be a taking, which implies the conſent of the owner to be wanting; and therefore no delivery of the goods from the owner to the offender, upon truſt, can ground a *larceny*. By the common law it was *no larceny* in a ſervant to run away with the goods committed to him to keep, but only a breach of truſt: but by ſtatute 21 Hen. VIII. c. 7. if any ſervant embezzles his maſter's goods to the value of 40 *s*. it is made felony, except in an apprentice and ſervants under eighteen years old. And if he had not the poſſeſſion, but only the care and overſight of the goods, as the butler of plate, the ſhepherd of ſheep, and the like; the embezzling of them is felony at common law. So if a gueſt robs his inn or tavern of a piece of plate, it is *larceny*; and ſo it is declared to be by 3 and 4 W. & M. c. 9. if a lodger runs away with the goods from his ready furniſhed lodgings. There muſt alſo be a carrying away; and a bare removal from the place in which he found the goods, though the thief does not quite make off with them, is ſufficient. But this muſt be felonious, i. e. done *animo furandi*, or as the civil law expreſſes it, *lucri cauſa*. The ordinary diſcovery of a felonious intent is where the party doth it clandeſtinely, or being charged with the fact denies it: beſides which, there are other circumſtances that evince a felonious intent, which are left to the conſideration of the court and jury. Moreover, this felonious taking and carrying away muſt be of the perſonal goods of another. Of things that adhere to a freehold, as corn, *grafs*, trees, and the like, or lead upon a houſe, no *larceny* could be committed by common law; but the ſeverance of them was, and in many things is ſtill, merely a treſpaſs: however if the thief ſevers them at one time, who only the treſpaſs is completed, and they are converted into perſonal chattels, in the conſtructive poſſeſſion of him on whoſe ſoil they are left or laid, and comes again at another time, when they are ſo turned into perſonalty, and takes them away, it is *larceny*, and alſo is the owner, or any one elſe, has ſevered them. And by 4 Geo. II. c. 32. to ſteal, or ſever with intent to ſteal any lead or iron fixed to a houſe, or in any court or garden belonging to it, is made felony, liable to tranſportation for ſeven years; and to ſteal underwood or hedges and the like, to rob orchards or gardens of fruit growing therein, to ſteal or otherwiſe deſtroy any trunks or the roots of maiden, when growing, are by 43 Eliz. c. 7. 13 Car. II. c. 2. 23 Geo. II. c. 26. and 31 Geo. II. c. 35. puniſhable criminally by whipping, ſmall fines, impriſonment and ſatisfaction to the party wronged, according to the nature of the offence. Moreover, the ſtealing by night of any trees, roots, ſhrubs, or plants, to the value of 5 *s*. is by 6 Geo. III. c. 36. made felony in the principals, aiders and abetters, and in the purchaſers knowing the ſame to be ſtolen; and by 6 Geo. III. c. 48 the ſtealing of any number-trees, as oak, beech, cheſtnut, walnut, aſh, elm, cedar, fir, aſp, lime, ſycamore and birch, and of any root, ſhrub, or plant, by day or night, is liable to pecuniary penalties for the firſt two offences, and for the third is conſtituted a felony, liable to tranſportation for ſeven years. Stealing ore out of mines is no *larceny*, except the ſtealing of ore out of mines of black lead, which is felony without benefit of clergy by 25 Geo. II. c. 10. Stealing of writings relating to a real eſtate is no felony, but a treſpaſs: bonds, bills and notes are goods of which *larceny* cannot be committed by common law; but by 2 Geo. II. c. 25. they are put upon the ſame footing with reſpect to *larceny*, as the money they were deſigned to ſecure. And by 7 Geo. III. c. 50 if any officer or ſervant of the poſt-office ſhall ſecrete, embezzle, or deſtroy any letter or packet, containing any bank-note or other valuable paper, ſpecified in the act; or ſhall fleal the ſame out of any letter or packet, he ſhall be guilty of felony without benefit of clergy. Or if he ſhall deſtroy any letter or packet with which he has received money for the poſtage, or advance the rate of poſtage, and ſecrete the money, he ſhall be guilty of ſingle felony. By 26 Geo. II. c. 19. plundering or ſtealing from any ſhip in diſtreſs, whether wreck or no wreck, is felony without benefit of clergy. For the laws relating to fiſh and game, ſee *Stealing of* FISH and GAME.

Of all valuable domeſtic animals, as horſes, and of all animals *domitæ naturæ*, which ſerve for food, as ſwine, ſheep, poultry, and the like, *larceny* may be committed; and alſo of the fleſh of ſuch as are *feræ naturæ*, when killed.

By the Roman law, the penalty of *ſimple* and *ſecret larceny* was the returning it two-fold; and of *manifeſt larceny*, four-fold: *manifeſt larceny* was, where the criminal was taken in the fact; *ſimple*, where he was not. The Lacedemonians never puniſhed *larceny*, provided the perſon was not caught in the fact; but, on the contrary, it was applauded as a mark of dexterity and addreſs.

The laws of Draco at Athens, which are ſaid to be written in blood, puniſhed it with death; but Solon afterwards changed the penalty into a pecuniary muct: and ſo the Attic laws in general continued. By the Jewiſh law, theft was only puniſhed with a pecuniary fine, and ſatisfaction

action to the party injured. Exod. chap. xxii. From these examples, as well as the reason of the thing, many learned and scrupulous men have questioned the propriety, if not lawfulness, of inflicting capital punishment for simple theft; and proposed either a pecuniary or a corporal punishment. Sir Thomas More in his Utopia, p. 42. and more lately the marquis Beccaria, Eſſ. on Crimes and Puniſhments, chap. xxii. have propoſed that kind of corporal puniſhment, which approaches the neareſt to a pecuniary ſatisfaction, viz. a temporary impriſonment, with an obligation to labour, firſt for the party robbed, and afterwards for the public, in works of the moſt ſlaviſh kind: neverthleſs the puniſhment of theft ſtill continues, through the greateſt part of Europe, to be capital. It is obſerved that our ancient Saxon laws nominally puniſhed theft with death, if above the value of 12 *d.* but the criminal was permitted to redeem his life by a pecuniary ranſom. But in the ninth year of Henry I. this power of redemption was taken away, and perſons guilty of great *larceny* directed to be hanged. See FELONY. *Petit larceny* by common law is only puniſhable by whipping, or by 4 Geo. I. c. 11. the puniſhment may be extended to tranſportation for ſeven years; but the puniſhment of *grand larceny*, or ſtealing above the value of 12 *d.* which ſum was the ſtandard in the time of king Athelſtan, eight hundred years ago, is at common law, regularly death; upon which Sir Henry Spelman obſerved, above a century ſince, when money was at twice its preſent rate, that while every thing elſe was riſen in its nominal value, and become dearer, the life of man had continually grown cheaper. And though the jury may exerciſe a kind of unwarrantable clemency, by bringing in *larceny* under the value of 12 *d.* and the benefit of clergy is allowed for the firſt offence; yet in many caſes of ſimple *larceny* this is taken away by ſtatute; as from horſe-ſtealing, taking woollen-cloth from off the tenters, or linen from the place of manufacture, ſtealing ſheep or other cattle ſpecified in the acts, thefts on navigable rivers above the value of 40 *s.* plundering veſſels in diſtreſs, or that have ſuffered ſhipwreck, ſtealing letters ſent by the poſt, and ſtealing deer, hares, and conies under the circumſtances recited in the *Waltham* BLACK *Act*.

The Circaſſians are ſaid to honour theft at this day; inſomuch that at their public feaſts, their youth are not ſuffered to drink, if they have not performed ſomething remarkable in that way. Solinus tells us, that in Sardinia there was a fountain that had the virtue of diſcovering a perſon that had committed *larceny*.

Compound or *mixed larceny* is that, which, beſides all the properties of the former, has the aggravation of taking from one's houſe or perſon. With reſpect to larceny from the houſe, ſee BURGLARY and HOUSE-*breaking*. It may be here obſerved, that the benefit of clergy is denied: 1. In all *larcenies* above the value of 12 *d.* from a church, or from a dwelling houſe, or booth, any perſon being therein. 2. In all *larcenies*, to the value of 5 *s.* committed by breaking the dwelling-houſe, though no perſon be therein. 3. In all *larcenies* to the value of 40 *s.* from a dwelling-houſe, or its out-houſes, without breaking in, and whether any perſon be therein or no. 4. In all *larcenies* to the value of 5 *s.* from any ſhop, warehouſe, coach-houſe, or ſtable, whether the ſame be broke open or not, and whether any perſon be therein or no: whether theſe offences are committed by day or by night. *Larceny* from the perſon is either by privately ſtealing; or by open and violent aſſault, uſually called robbery. The offence of privately ſtealing from a man's perſon, above the value of 12 *d.* as by privately picking his pocket or the like, without his knowledge, was debarred of clergy, ſo early as by the ſtatute 8 Eliz. c. 14. For the other kind of *larceny* from the perſon, ſee ROBBERY. See alſo FELONY.

Perſons who buy or receive any ſtolen goods, knowing the ſame to be ſtolen, ſhall be deemed acceſſaries after the fact: 3 W. c. 9. and by 4 Geo. c. 11. they may be tranſported for fourteen years: and by 5 Anne, c. 31. Such perſons and thoſe who conceal any felons or thieves ſhall be deemed acceſſary to the felony, and being convicted on the teſtimony of one witneſs ſhall ſuffer death as a felon convict. Perſons offering for pawn or ſale goods ſuſpected to be ſtolen, may be ſeized and conveyed by a conſtable or other peace officer before a juſtice, who may commit them for any time not exceeding ſix days for examination, and afterwards, if the goods were ſtolen or clandeſtinely obtained, to the common gaol or houſe of correction. 30 Geo. II. c. 24. Perſons advertiſing a reward for helping to ſtolen goods, and alſo the printer and publiſher of ſuch advertiſement, ſhall reſpectively forfeit 50 *l.* with coſts. 25 Geo. II. c. 36. And by 4 G. c. 11. thoſe who receive ſuch reward, without apprehending the felon and bringing him to trial, ſhall be guilty of felony in the ſame manner as if they had ſtolen the ſame.

The charges of proſecution and conviction in reſpect of any grand or petit *larceny* may, by order of court, and at the prayer of the proſecuter, be paid by the county treaſurer, with a reaſonable allowance for his time and trouble: 25 Geo. II. c. 36. And by 27 Geo. II. c. 3. reaſonable charges may be allowed and paid in the ſame manner, to a poor perſon who is required to give evidence in Middleſex: theſe charges muſt be paid by the overſeers of the poor where the perſon was apprehended. It is provided by ſtatute, that every perſon who ſhall apprehend any one guilty of houſe-breaking or private ſtealing, to the value of 5 *s.* and proſecute him to conviction, and all the executors or adminiſtrators of a perſon ſlain in endeavouring to apprehend a houſe-breaker or felon, ſhall have a certificate without fee, under the hand of the judge, certifying ſuch conviction, &c. which certificate ſhall be enrolled by the clerk of the peace of the county where it is granted, and may be once aſſigned over and no more. By virtue of this certificate the original proprietor, or aſſignee of the ſame, ſhall be diſcharged from all pariſh and ward offices, within the pariſh or ward where the felony was committed: 10 & 11 W. c. 23. Every ſuch perſon, and alſo the executors and adminiſtrators of a perſon killed as before, ſhall alſo have another certificate, which, on being tendered to the ſheriff and demand made, ſhall entitle him to the ſum of 40 *l.* without fee, in one month after the tender and demand; on pain of forfeiting double with treble coſts. 5 Anne, c. 31. See DISCOVERY of *Accomplices*.

The ſheriff on producing the certificates and the receipts for the ſaid rewards, may deduct the ſame from his accounts; and if he have not money in his hands, he ſhall be repaid out of the treaſury, on certificate from the clerk of the pipe; or he may immediately apply to the commiſſioners of the treaſury, who ſhall pay the ſame without fee. 3 Geo. c. 15.

LARCH-*tree*, *Larix*, in *Botany*. Linnæus refers this to the genus of PINE. The characters are theſe: it hath male and female flowers, growing ſeparate on the ſame tree; the male flowers are diſpoſed in a ſcaly katkin, without a petal; the female flowers are diſpoſed in a conical ſhape, having no petals, but a ſmall germen, which afterward becomes a nut with a membranaceous wing, incloſed in the ſcales of the cones.

The common cone-bearing *larch-tree* grows naturally upon the Alps and Apennines, and has been lately much propagated in England. Thoſe trees raiſed from ſeeds thrive beſt in the moiſt ſoil and ſituation. There are two varieties of this tree, one of which is a native of America, and the other of Siberia; neither of which thrive well in this climate. In Switzerland the wood of the common *larch-tree* is uſed for building and covering the houſes; and in other countries, where it abounds, it is preferred for every purpoſe to all the kinds of fir. In many places there are ſhips built of this wood, which are ſaid to be durable; and, therefore, this may be a very proper tree for planting upon ſome of the cold barren hills in many parts of England, which, beſides the profit they would yield to their proprietors, would alſo conduce to national benefit. The *Venice* TURPENTINE is extracted from the *larch-tree*. See CEDAR.

LARENTINALIA, in *Antiquity*, a feaſt held among the Romans on the 23d day of December, but ordered to be obſerved twice a year by Auguſtus; by ſome ſuppoſed to have been in honour of the Larea, but by others, with more probability, in honour of Acca Laurentia; and to have been the ſame with LAURENTALIA.

LARES, among the *Ancients*, derived by Apuleius, De Deo Socratis, p. 669, from *ſar*, *familiaris*; a kind of domeſtic genii, or divinities, worſhipped in houſes, and eſteemed the guardians and protectors of families; ſuppoſed to reſide more immediately in the chimney corner.

The *Lares* were diſtinguiſhed from the PENATES, as the former were ſuppoſed to preſide over houſe-keeping, the ſervants in families, and domeſtic affairs, and the latter were the protectors of the maſters of families, their wives and children: accordingly the *Lares* were dreſſed in ſhort ſuccinct habits, to ſhew their readineſs to ſerve, and they held a ſort of cornucopia in their hands, as a ſignal of hoſpitality and good houſe-keeping. According to Ovid there were generally two of them, who were ſometimes repreſented with a dog at their feet. Faſt. 5. v. 146.

Plutarch diſtinguiſhes good and evil *Lares*, as he had before done good and evil Genii.

There were alſo ſome public, others private *Lares*.

Apuleius tells us the domeſtic *Lares* were no more than the ſouls of departed perſons, who had lived well, and diſcharged the duties of their ſtation; whereas thoſe who had done otherwiſe, were vagabonds, wandering about, and frightening people, called *Larvæ* and LEMURES.

The *Lares* were alſo called *Privati*, and were worſhipped

under

under the figures of little marmosets, or images of wax, silver, or earthen ware.

The public *Lares* were also called *Compitales*, from *compitum*, a cross-way; and *Viales*, from *via*, a way, or public road; as being placed at the meetings of roads, and in the highways, and esteemed the patrons and protectors of travellers.

Their private *Lares* took care of particular houses and families: these they also called *Præstites*, from *præsto*;

Quod præstant aculis omnia tuta suis. Ovid. Fast.

They gave the name *Urbani*, i. e. *Lares* of cities, to those who had cities under their care; and *Hostilii*, to those who were to keep their enemies off. There were also *Lares* of the country, called *Rurales*, as appears by several antique inscriptions.

The *Lares* were also genial gods, and were supposed to take care of children from their birth. It is for this reason that when Macrobius tells us the Egyptians had four gods who presided over the birth of children, viz. the *Genius*, *Fortune*, *Love*, and *Necessity*, called *Præstites*, some interpret him as if he had said, the Egyptians had *Lares*; but they have mentioned that there was a great difference between the *Lares* of the Romans, and the Præstites of the Egyptians. However, the learned Mr. Bryant affirms that they were the same.

The ancients differ extremely about the origin of the *Lares*. Varro and Macrobius say, that they were the children of Mania; Ovid makes them the issue of Mercury, and the naiad Lara, whom Lactantius and Ausonius call *Larunda*; Apuleius allures us they were the posterity of the Lemures; Nigridius, according to Arnobius, made them sometimes the guardians and protectors of houses, and sometimes the same with the *Curetes* of Samothracia, which the Greeks call *Idæi dactyli*. Nor was Varro more confident in his opinion of these gods; sometimes making them the manes of heroes, and sometimes gods of the air.

T. Tatius king of the Sabines, was the first who built a temple to the *Lares*. The chimney and fire-place in the house were particularly consecrated to them.

Tertullian tells us the custom of worshipping the *Lares* arose from this, that they anciently interred their dead in their houses; whence the credulous people took occasion to imagine their souls continued there also, and proceeded to pay them divine honours. To this it may be added, that the custom being afterwards introduced of burying in the highways, they might hence take occasion to regard them as gods of the highways.

The victim offered to the *Lares*, in the public sacrifices, was a hog: in private, they offered them wine, incense, a crown of wool, and a little of what was left at the table. They also crowned them with flowers, particularly the violet, myrtle, and rosemary. Their symbol was a dog, which was usually represented by their side, on account of its fidelity, and the service it does to man, in watching his house. They were sometimes also represented as clothed in a dog's skin.

See farther on the *Lares*, in Arnobius, Lactantius, Augustine De Civit. Natalis Comes, Lambin. on Plaut. Aulul. and on Hor. Casaubon on Sueton. &c.

The term *Lares*, according to Mr. Bryant, was formed from *larus*, an ancient word by which the ark was represented: and he supposes that the *Lares* and MANES were the same domestic deities under different names; and that by these terms the Hetrurians and Latines denoted the *divi arkitæ*, who were no other than their arkite ancestors, or the persons preserved in the *larus* or ark; the genius of which was Isis, the reputed parent of the world. He observes farther, that they are described as dæmons and genii, who once lived on earth, and were gifted with immortality. Arnobius, lib. iii. p. 124. styles them, *Lares quosdam genios & functorum animas*; and he says, that according to Varro de Ling. Latin. lib. viii. p. 113, they were the children of Mania. Huetius Demonst. Prop. 4. p. 139, adds, that Mania had also the name of Larunda; and she is styled the mother of the dæmons. By some she is called Lara, and was supposed to preside over families; and children were offered at her altar in order to procure her favour. Macrob. Sat. lib. i. c. 7. p. 154. In lieu of these they in aftertimes offered the heads of poppies, and pods of garlick. Anal. of ancient Mythol. vol. ii. p. 449. &c.

The pantheons, or images representing several gods at once, were also called *Lares*. Harpocrates was one of these.

LARGE, a *Sea Term*, applied to the wind, when it crosses the line of a ship's course in a favourable direction, particularly on the beam or quarter. Thus, if a ship steer west, then the wind in any point of the compass to the eastward of the south or north, may be called *large*, unless when it is directly east, and then it is said to be right aft. *Sailing large* is, therefore, advancing with a *large* wind, so as that the sheets are slackened and flowing, and the bow-lines entirely disused. This phrase is generally opposed to sailing CLOSE-*hauled*.

LARGE, in the *Manege*. A horse is said to go *large*, or wide, when he gains or takes in more ground in going wider from the center of the volt, and describing a greater circumference. To make a horse go *large*, you must give him the aid of your inner heel. See ENLARGE.

LARGET, in *Music*. See CHARACTER.

LARGHETTO, in the *Italian Music*, signifies a movement something slow, yet a little quicker than LARGO.

LARGO, in the *Italian Music*, a slow movement, one degree quicker than adagio, and two than grave. See TIME.

LARK, *alauda*, in the Linnæan system of *Zoology*, a distinct genus of birds, of the order of the *passeres*: the characters of which are, that the tongue, which is bifid, has a rim or margin round it, and is membranaceous and pointed; the beak is straight and pointed, and bending towards the point; the maxillæ equal in size; and the claw of the hinder toe is longer than any of the other toes; the toes are also divided to their origin, and the nostrils are covered with feathers or bristles. We have in England four species of this bird. 1. The common *lark*. 2. The *wood-lark*. 3. The *tit-lark*. And, 4. The small-crested *lark*. And beside these there are several exotic species of birds, properly referable to this genus; as the LUCUSTELLA, CALANDRA, SPIOLA, SPINOLETTA.

The common field *lark*, or *sky-lark*, the *alauda arvensis* of Linnæus, is well known, and not less esteemed for its delicacy at table, than for its singing. This and the *wood-lark* are the only birds that sing as they fly; this rising as it soars, and lowering it all it quite dies away as it descends. It will often soar to such a height, that we are charmed with the music when we lose sight of the songster. It also begins its song before the earliest dawn. It continues its harmony several months, beginning early in the spring, on pairing. It is very fat in winter, and taken in prodigious numbers; it builds on the ground, beneath some clod, and lays four or five eggs. These birds are taken in greatest number, in the neighbourhood of Dunstable; the season begins about the fourteenth of September, and ends the twenty-fifth of February; and during that time some thousands are caught to supply the markets of London. Those taken in the day are caught in CLAP-*nets*, till the fourteenth of November. See DURING. But when the weather becomes gloomy, and also in the night, the larker makes use of a trammel net, twenty-seven or twenty-eight feet long, and five broad, which is put on two poles eighteen feet long, and carried by men under each arm, who pass over the fields, and quarter the ground as a setting dog. When they see or feel a *lark* strike the net, they drop it down, and thus the birds are taken. The darkest nights are the properest for this sport; and the net will not only take *larks*, but all other birds that roost on the ground, among which are woodcocks, snipes, partridges, quails, field-fares, and several others.

In the depth of winter people sometimes take great numbers of *larks* by nooses of horse-hair. The method is this: take a hundred, or two hundred yards of packthread; fasten at every six inches a noose made of double horse-hair; at every twenty yards the line is to be pegged down to the ground, and so left ready to take them. The time to use this is when the ground is covered with snow, and the *larks* are to be allured to it by some white oats, scattered all the way among the nooses; they will soon fly to these, and in eating will be hung by the nooses. They must be taken away as soon as three or four are hung, otherwise the rest will be frighted; but though the others are scared away just where the sportsman comes, they will be feeding as the other end of the line, and the sport may be thus continued a long time.

The *sky-lark* is a kind of mocking bird; for it will catch the note of any other which hangs near it, even after its own note is lost. On this account, the bird-fanciers often place the *sky-lark* next to one which hath not been long caught, in order, as they term it, to keep the caged *sky-lark* perfect.

The *wood-lark*, or *alauda arborea* of Linnæus, is smaller than the common *lark*, and is shorter bodied; the colours are paler, and its note is less fonorous and less varied, though not less sweet; it generally flies in large flocks, and as it is in the air sings with a voice more like that of the blackbird, than of the common *lark*, and it will also sing in the night; it has a circle of white feathers like a crown, reaching from one eye to the other across the head; the tip of its tail is white, and it sits on trees. These are its distinctions from the common *lark*. This, like

like the other, builds on the ground, and makes its nest on the outside with moss, and lays five eggs, which are dusky, and blotched with deep brown. The males of this and the last species are known from the females by their superior size.

The *wood-lark* is one of the sweetest of our singing-birds, and is indeed very little inferior to the nightingale, when in good health; for we are not to judge by such as are made feeble by improper food, or want of cleanliness in their cages.

It is one of the tenderest birds we have, and yet it breeds the soonest of any that we know of. They principally frequent gravel grounds, and the sides of hills, that are exposed full to the sun; and if there be any stumps of oaks in these places, they always resort to them. The females couple with the males in the beginning of February, at which time, and never before, they part with their last year's brood; immediately after coupling they betake themselves to building their nest. They generally build in lay, or grounds where the grass is rank, and is grown brown. The principal material they use is dry grass, and they always choose some place sheltered by a good tuft for their nest, to defend themselves from the cold winds, which are very severe at that season. They feed their young principally with a small red worm; but it is very difficult to find this kind, to feed a nest of them under our care, and they will not do well without it; so that they scarce ever come to any thing this way.

The young branchers are taken in June, July, and August. After this they may be taken in large numbers at the latter end of September, which is their general flight season, and then from the beginning of January to the beginning of February, at which time they get together to couple for breeding. Those that are taken in the summer months are usually taken in nets, by the help of a hawk.

The sportsman is to go out in a dewy morning, and fixing on some hill, he is to go to that side of it which faces the rising sun; for this place they are sure to frequent. He is to take out a hawk, and a small net, at the end of a stick; when he espies a bird he is to shew the hawk, on which it will squat down, and on his approaching nearer, and making the hawk flutter over the place, the bird will only lie so much the closer, so that he may go up and lay the net over it, and thus take it, without hurting it.

The best *wood-larks* that are kept in cages have been caught in this manner. A better way of taking numbers of them is to prepare a net made in the same manner as the common net for taking partridges, only with the meshes much smaller; three or four persons are to go out with this, and one of them is to take out a hawk, which serves in the same manner for the *larks* as the setting-dog does for the partridges.

Wherever a flock of these *larks* are seen together, as is very common, the whole flight keeping with the female till the next coupling season, the hawk is to be shewn, and on his hovering they will all lie still, and the net may be easily drawn to completely over them, that not one can escape. The best time for taking this bird for the cage, is in July, or the preceding or following month; those that are put into the cage at this time sing presently, but their song time is not lasting, for they soon fall to moulting, in which state many die; but if they get over it, they commonly prove very healthful afterwards, and become very tame and familiar, and sing sweetly. Those which are taken in the latter end of September, are generally very strong and sprightly; but they do not sing till after Christmas. Those taken in January and February finally prove the best of all; they generally begin singing in two or three days, or at the utmost in a week after they are taken.

The method of keeping them in health in the cage, is this: there must be two pans of food, the one containing meat, the other oatmeal and hempseed. A very good food is the following: boil an egg very hard, to which add the crumb of a halfpenny loaf, and as much hempseed; let the egg be chopped very small, and the hempseed bruised in the mortar; when these are mixed, the bread is to be crumbled in among the rest, and the whole to be rolled together with a common rolling-pin, and kept for use.

There must be some fine small gravel strewed at the bottom of the cage, and renewed at farthest once in a week. This will prevent the bird's feet from getting hurt by being clogged with the dung; and his basking in this will keep him also from growing lousy, after which few come to good. There must be a perch in the cage, and it must either be lined with green bays, or made of fine matting, which the *lark* is very fond of.

When the bird is first taken, some meat must be strewed upon the sand in the bottom of the cage; for the bird will be sometimes almost famished before he finds the meat in the pan.

The cock-bird of this kind is known from the hen by the loudness and length of his call, by his taller as he walks about the cage, and by his doubling his notes in the evening, as if he was going with his mate to roost. A better rule than all others, however, is his singing strong; for the hen *wood-lark* sings but very weakly.

Both the cock and hen of this kind are tender, and subject to many disorders; the principal of these are cramps, giddiness of the head, and breeding hen. Cleanliness is the best cure for the first and the last of these complaints, but we know of no cure for the other. A good strong bird, however, will often last very well five or six years, and often improve all the time.

The *lark* is not only a very agreeable bird for the cage, but it will also live upon almost any food, so that it have once a week a fresh tuft of three-leaved grass put into the cage with it.

The *sky* and *wood-lark* differ in the time of their breeding; the former not producing her young ones till May, the latter hatching them in March. In winter it is common to see vast flocks of *sky-larks*; and yet it is observed, that there are fewer of their nests found in the season, than of any birds that are in any degree common among us. The *sky-lark* sometimes builds among corn, sometimes among high grass, and seldom has more than three young ones at a brood, scarce ever more than four; so that it is the more wonderful whence the large flights we see come. The young may be taken out of the nest at a fortnight old, and are so hardy, that they will easily be brought up. The best food is sheep's heart chopped with egg, and afterwards oatmeal, bruised hempseed, and bread, with a little egg among it. They should have clean sand at the bottom of the cage, but they need no perches.

The *tit-lark* is called by authors the *alauda pratorum*, or *alauda pratensis*. This sits upon trees like the *wood-lark*, is smaller than the common *lark*, and has more of a dusky greenish hue, and is less beautiful in its colour than the common *lark*. This, like the other *larks*, builds its nest among the grass, and lays five or six eggs; it has a very remarkable fine note, singing in all situations, on trees, on the ground, while it is sporting in the air, and particularly in its descent. This bird, and many others, such as the thrush, blackbird, willow-wren, &c. become silent about Midsummer, and resume their notes in September. It is thought that we have in England, beside the common species of *tit-lark*, another kind, which differs from the common kind, in that it is larger, has less greenness in its colouring, has paler-coloured feet, and shorter heels.

The last, or crested *lark*, is the *alauda cristata minor* of authors: this is like the large crested *lark*, but is much smaller; its crest is very long in proportion to its size, and its feet are red; it is all over of a pale brown colour, and is seen in flocks in the northern parts of England.

There is another species, called the *red lark*, which is found in the neighbourhood of London, in North America, and in the south of Europe; though it is rarely met with in this country. It is equal in size to the common *lark*; a white line crosses each eye, and another passes beneath; the bill is thick; the chin and throat whitish; the head, neck, back, and coverts of the wings, of a ruffy brown, spotted with black; breast whitish, with dusky spots; belly of a dirty white; the middle feather of the tail black, edged with brown; the two exterior white; and the legs of a pale brown. This species was first discovered by Mr. Edwards, who observes, that, when the wing is gathered up, the third primary feather reaches to the tip of the first. Ray and Pennant.

LARK, *grasshopper*. See LOCUSTELLA.

LARK, *sea*, *cheiranthus littoreus* of Linnæus, is common on our shores in summer, but the number is not considerable. The bill of this species is half an inch long; the upper half orange-colour, the lower black; from hence to the eyes is a black line; the cheeks are of the same colour; the forehead white, bounded by a black band that passes from eye to eye; the crown of the head is of a fine light brown; the upper part of the neck is encircled with a white collar, the lower part with a black one; the back and coverts of the wings of a light brown; the breast and belly white; the tail brown, tipt with a darker shade; and the legs yellow. This bird lays four eggs, of a dull whitish colour, sparingly sprinkled with black. At the approach of winter it disappears. Pennant.

The *sea-lark* is also a name given by some authors to the STINT.

LARK, *willow*. See *Lesser Red* SPARROW.

LARKSPUR, or LARK'S-HEEL, *delphinium*, in *Botany*, a genus of the *polyandria trigynia* class. Its characters are these: the flower is composed of five unequal petals; the upper petal, extended at the hinder part into a tubular,

obtuse tail; it has a bifid nectarium, situated in the center of the petals, and many small stamina, with three oval germina, which become so many connected capsules, each having one cell, filled with angular seeds.

Miller enumerates eleven species of this plant, cultivated in the gardens of the curious, for the beauty of the flowers; and beside these a number of other varieties produced by a careful management of the seed saved from good flowers. They are to be raised by sowing the seeds in autumn, soon after they are ripe. Some sow them in spring, but the plants are thus never so strong, nor are the flowers so large. When the young plants have got a little strength, they should either be pulled up, or transplanted so as to have them at ten inches distance every way. They will now require no farther care, but will flower in July. See STAVESACRE.

LARMIER, in *Architecture*, a flat, square, massive member, of the cornice, between the cymatium and the ovolo; so called from its use, which is to disperse the water, and cause it to fall at a distance from the wall, drop by drop, or, as it were, by tears; *larme*, in French signifying a *tear*. See *Tab. Architect. Fig.* 9. *Fig.* 25, N° 2. The *larmier* is also called CORONA; and in English, the DRIP.

LARVA, in *Natural History*, a name given by Linnæus to insects in that state, called by other writers *eruca* or CATERPILLAR. See *Transformation* of INSECTS.

LARVÆ, in *Antiquity*, derived from the Hetrurian word *lar* or *lari*, signifying *prince* or *lord*, denoted the ghosts of the deceased, considered as wicked and mischievous. Hence is formed the term *larvatus*, i. e. *larved indeed* or DEMONIAC. The ingenious Mr. Farmer urges the etymology and use of this term to prove, that the heathen demons were human ghosts. Ess. on the Demoniacs, p. 27, &c.

The *larvæ* were also called LEMURES.

LARUS, in the *Linnæan System of Ornithology*, is a genus of the order of *anseres*: the characters of which are, that the bill is strong, strait, and bending near the end; that there is an angular prominence in the lower mandible; the nostrils are linear, wider in the fore part and situated in the middle of the bill; the tongue is a little cloven; the body light, and covered with a thick plumage, wings large, legs short, and feet fissil. They are great flyers, very clamorous and noisy, and feed on fish. Linnæus enumerates eleven different species. Ray observes, that there are properly two subordinate genera of these birds; the first is of those which are large, and have an even not forked tail, and have a tubercle in the lower chap of the bill; the other of the smaller ones, which have all forked tails without any tubercle. Of the first genus are the *great-gull*, the *herring-gull*, the *sea-mall*, the *sea-mew*, the *tarrock*, the *pewit*, the *gannet*, the *cotarakta*, the *martinmasse*, the *coddy-moddy*, the *winder-mew*, the *cepphus*, the *brown-tern*, and the *gavinita*: and of the second or smaller kind are the *sterna*, which Linnæus has made a distinct genus, the *fisherkin*, the *scare-crow*, and four species of the *larus fuliginosus*: all which see under their several heads. See GULL.

LARUS *fuliginosus*, in *Ornithology*, the name of a peculiar kind of bird, accounted by many to be of the *larus* or gull-kind, but having its feet not webbed, as in the other birds of that genus, but the toes loose, as in land-fowls. There are four known species of this bird. 1. A black one, something smaller than the common sea-swallow, and having a forked-tail. 2. A black kind, with a greyish white breast and belly, and remarkable for the length of its wings. 3. A grey kind, of the size of a black-bird, with a very long tail and short wings. 4. A brown one, with yellow spots. The first and last are common on our own coasts, the two others are described by Aldrovand. They all feed on fish. Ray.

LARYNGOTOMIA, in *Surgery*, formed of λαρυγξ, and τεμνω, *I cut*, the same with what is otherwise called BRONCHOTOMY.

LARYNX, λαρυγξ, in *Anatomy*, the upper part or head of the trachea, lying below the root of the tongue, and before the pharynx.

The *larynx* is one of the organs of respiration, and the principal instrument of voice.

Its body is almost wholly cartilaginous, and it is to be constantly open to give room for the air to pass and repass. Its figure is circular, though it jets out a little before; and is a little flatted behind, lest it should incommode the œsophagus, whereon it is placed.

The *larynx* is of different diameters, according to the different ages; in young people it is narrow, whence their voice comes to be acute; in those more advanced in years, it is more ample, which occasions their voice to be stronger and deeper. In men it is bigger than in women, for which reason men's voice is more grave than that of women.

It appears the less in women, because the glands situate at the bottom of the *larynx*, are bigger in women than in men. The *larynx* moves at the time of deglutition: when the œsophagus is lowered for the reception of the food, the *larynx* raises itself to compress it, and facilitate its descent.

There are five kinds of parts belonging to the *larynx*, viz. *cartilages*, *muscles*, *membranes*, *nerves* and *glands*. Its cartilages are the THYROIDES, CRICOIDES, ARYTÆNOIDES, GLOTTIS and EPIGLOTTIS, by means of which it can easily dilate and contract, shut and open itself. These form the whole body of the *larynx*, and grow dry, and harden, in proportion as the person grows old, when the *larynx* sometimes appears as if it were bony.

The biggest of these is the *thyroides* or *scutiformis*; this guards the fore-part, and has its name from some supposed resemblance that it bears to a shield. It is of a concavo-convex square figure, the hollow part being inward, and the gibbous outward, having a little prominence in the middle, called *pomum Adami*, as if some of the forbidden fruit had stuck in Adam's throat, and occasioned that swelling.

The second is called *cricoides*, or *annularis*, from its resemblance to a ring which the Turks put on their thumb for the drawing of their bows. The fore part of this is very narrow, coming under the other cartilage; but behind, it is broad, thick, and strong, being, as it were, the basis of all the others.

The third and fourth are called *arytænoides*, or *guttales*, from the figure of an ewer, which these two together somewhat resemble. At the juncture of these there is a little cleft, or chink, in form of a little tongue, and for that reason called *glottis*, or *lingula*. Through this chink the air descends into the lungs, and the pituitous matter ejected by coughing, in catarrhs, is let out. It serves also for modulating the voice, and is imitated in flutes, and the pipes of organs.

Over the glottis lies a fifth cartilage, called the *epiglottis*, which is very thin and soft, and in non-adults almost membranous, concave on the under-side, and convex on the upper: it defends the entrance of the *larynx*, and hinders the liquids, which in drinking slip over it into the œsophagus, from falling into the trachea.

The *larynx* has several pair of muscles, which serve to move its several cartilages, and to contract or dilate them at pleasure: two pair of them are common, the other proper: the proper are those which have both their origination and insertion in the *larynx*; the common have only their insertion there.

Of the former kind are the cricothyroides, or CRICOTHYROIDÆUS, which moves the cruciform cartilage; the CRICO-ARYTÆNOIDÆUS posticus, which serves, by its contraction, to draw the arytænoides cartilage, and to open the rima. The third is the ARYTÆNOIDÆUS, which serves to bring the two cartilages of that name together, and to shut the rima. The fourth is the CRICO-ARYTÆNOIDÆUS lateralis; and the fifth the THYRIDO-ARYTÆNOIDÆUS, which shuts the *larynx*.

The common muscles are the STERNO-THYROIDÆUS, which serve to draw down the thyroide cartilage, and the HYO-THYROIDÆUS which lift up that cartilage.

Winslow adds another class of muscles, which he calls collateral, being those that are inserted by one portion in the *larynx*, without appearing to contribute any thing to the motions of it: of this kind are the THYRO-*pharyngæi*, CRICO-*pharyngæi*, &c.

The *larynx* has but two membranes; the one *external*, which is a continuation of that which covers the trachea; the other *internal*, which is the same that lines the whole mouth.

It receives two branches of nerves from the recurrents, and is moistened by four large glands; two situate above called TONSILS; and two underneath, called THYROIDÆ.

The *larynx* is of very considerable use, not only in forming and modulating the voice, by the different aperture of its rima, or chink, but also in compressing the lungs to a greater or less degree, by the air; for if the internal diameter of the *larynx* had been equal to that of the trachea, the lungs could then have undergone little or no compression at all; nor, consequently, without the *larynx* could we have reaped any advantage from breathing, because the air would not have resisted that force wherewith it is driven out in expiration; nor, consequently, could the compression have been made in the lungs, which is found necessary for the commixtion of the globules of the blood, and the mixing of the two fluids, air and blood, together.

For the action of the *larynx* in sound, see GLOTTIS, and SOUND; see also EPIGLOTTIS, TRACHEA, &c.

LASANON, a word used by different authors in very dif-

ferent senses; some applying it to the trivet commonly used in kitchens; others to a close-stool; and others, among whom are Hippocrates, and the ancient physicians, for a sort of chair, contrived for a woman in labour to sit in, as being to made, that the weight of the child, when born, should help to draw away the secundines.

LASER *Cyrenaicum*, in the *Materia Medica*, a name supposed to be given by the ancient Greeks to the gum we at this time call ASSA *fœtida*. The word *asa*, or, as it was originally written, *afa*, was evidently formed on the *laser* of the Greeks; but there was also an *afa* mentioned by the old authors very different from this, being a fragrant and sweet-scented gum. This sweet gum was evidently the *laser* and *afa*, or *affa*, of the ancient Greeks; and the *silphium* was the plant which produced it. This plant grew in Cyrene, and furnished it a long time; but in the days of Pliny it was in a manner lost. The people of Cyrene found it more profitable to feed their cattle upon the *silphium*, than to gather its gum.

Pliny continues to tell us, that by the feeding cattle on this plant, it was so perfectly destroyed, in a course of years, that there had been, of a long time, only one plant of it seen, and that reckoned to great a curiosity, that it was sent as a present to the emperor Nero.

When Cyrene no longer afforded the *silphium*, it was sought for in other places. The original *afa*, or *laser*, had the smell of *myrrh*, but more mild and agreeable; and the *afa* of succeeding times had that of leeks or garlic, and thence was distinguished by the name *fœtida laserum*.

LASERWORT, *laserpitium*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: it hath an umbellated flower, composed of many small umbels; the general umbel is uniform; the flowers have five equal heart-shaped petals, and five stamina; the roundish germen is situated under the flower, which afterward becomes an oblong fruit with eight longitudinal wings or membranes, resembling the fliers of a water-mill; the fruit divides into two parts, each containing one seed. There are nine species.

These plants grow naturally in the south of France, in Italy, and Germany, and are preserved in botanic gardens for the sake of variety; they have no great beauty. It is generally supposed, that the *silphium* of the ancients was procured from one species of this genus, but from which of them we are at present ignorant. All the species, if wounded, drop a very acrid juice, which turns to a resinous gummy substance, very acrimonious. This was externally applied by the ancients to take away black and blue spots that came by bruises and blows, as also to take away excrescences: it was also by some of the ancients prescribed in internal medicines, but others have cautioned people not to make use of it this way, from the effects which they mention to have been produced from the violence of its acrimony.

All these plants are extremely hardy, so will thrive in most soils and situations. They are propagated by seeds, which, sown in autumn, will afford plants in the spring, that may be transplanted in the following autumn. Miller.

LASH, or LACE, in the *Sea Language*, signifies to bind or make fast.

Lashing, which also denotes a piece of rope used to fasten or secure any moveable body in a ship, or about her masts, sails, and rigging, is chiefly used for binding up to the ship's side, muskets, buts of water or beer, or pieces of timber, to make spare top-masts.

LASHERS are properly those ropes only which bind fast the tackles, and the breeches of the ordnance, when they are haled or made fast, within board.

LASK, a term used by *Farriers*, for a looseness in horses, often fatal to them.

LASKETS, or LATCHES, in a *ship*, are small lines, like loops, fastened, by sewing into the bonnets and drablers, in order to lace the bonnets to the courses, or the drablers to the bonnets.

LA-KING, a sea-term for going large, or veering.

LASSITUDE, among *Physicians*, expresses that weariness, or heaviness, of members, that proceeds from a distempered state of body, and not from exercise; either from an increase of bulk, a diminution of proper evacuation, or too great a consumption of that fluid which is necessary to maintain the force and spring of the solids, as in fevers, and convulsions: or from a vitiated secretion of that juice, whereby the fibres are not supplied either in due quantity or quality.

The remedy, in the first case, is evacuation; in the latter, a proper diet, or such alterative medicines as influence such a secretion.

LAST, or LEST, in general, signifies the burden or load, of a ship.

LAST is also used for a certain weight and measure, which is various in various countries; though, in the general, the *last* is estimated at four thousand pounds WEIGHT. A *last* of cod-fish, white herrings, meal, and ashes for soap, is twelve barrels; of corn, or rape-seed, ten quarters; of gunpowder, twenty-four barrels, or two thousand four hundred pounds weight; of red-herrings, twenty cades; of hides, twelve dozens; of leather, twelve dickers; of pitch, or tar, fourteen barrels; of wool, twelve sacks; of flock silk, a thousand; of flax, or feathers, one thousand seven hundred pounds weight.

LAST, in the marshes of Kent, a court held by the twenty-four jurats, and summoned by the bailiffs; wherein orders are made to lay and levy taxes, impose penalties, &c. for the preservation of the said marshes.

LAST *Heirs*, is he to whom lands come by escheat, for want of lawful heirs; which in many cases, is the lord whereof they are held; but in others the king.

LAST *Will*. See WILL.

LAST, *Post*. See POST-*Last*.

LASTAGE, or LESTAGE, according to Rastal, is a duty exacted in some fairs and markets, for carrying things bought whither one will.

LASTAGE, according to another author, is properly that custom which is paid for wares sold by the *last*.

In the law of Ric. II. *Lastage* is taken for the BALLAST, or for lading of a ship.

LASTAGE is sometimes also used for garbage, rubbish, or such filth.

LATCHETS. See LASKETS.

LATE *Flowers*. See FLOWERS.

LATEEN-*Sail*, in *Sea Language*, a long triangular sail extended by a *lateen*-yard, frequently used by ashers, polacres, settees, and other vessels navigated in the Mediterranean sea.

LATENT *acids*. See ACID.

LATERAL. See COLLATERAL, MULTILATERAL, and QUADRILATERAL.

LATERAL *equation*, in *Algebra*, denotes a simple equation, an EQUATION whose root is only of one dimension.

LATERAL *line*. See LINE.

LATERAL *palsy*. See PALSY.

LATERAL *operation*. See LITHOTOMY.

LATERALIS *morbus*, a name given by some writers to the PLEURISY.

LATERALIS *nervi musculus*, in *Anatomy*, a name given by many authors to that muscle of the face which Albinus has called, from its office, the *levator labii superioris alæque nasi*. It is also called the *obliquus nasi*.

LATERALIS *rectus capitis*. See RECTUS.

LATERAN was originally the proper name of a man, whence it descended to an ancient palace in Rome, and to the buildings since erected in its place; particularly a church called *S. John of Lateran*; which is the principal see of the popedom.

LATERAN, *councils of the*, are those held in the basilica of the *Lateran*: of these there have been five, held in 1123, 1139, 1179, 1215, and 1513.

LATERAN, *Canons Regular of the Congregation of the*, is a congregation of regular canons, whereof that church is the principal place, or seat.

It is pretended there has been an uninterrupted succession of clerics, living in community from the time of the apostles; and that a number of these were established in the *Lateran* in the time of Constantine. But the canons were not introduced till the time of Leo. I. and these held the church eight hundred years, till the reign of Boniface, who took it from them, and placed secular canons in their room: one hundred and fifty years after, the regulars were reinstated.

A LATERE, a Latin term used to denote the qualification of cardinals, whom the pope sends as legates into foreign courts; who are called cardinals *à latere*, as being his holiness's counsellors in ordinary, and assistants. See LEGATE.

The guards of princes were heretofore called *laterones*, because always attending at their sides. *à latere*.

Du-Cange, in his Glossary, says, there were anciently comites *à latere*, and monitors *à latere*.

LATERCULUM, among the *Romans*, was used for a roll or list of all the magistrates and military officers under the Roman emperors, with an account of their respective offices and fees.

LATEX, in *Chemistry*, a name by which Van Helmont has, in some of his writings, called the famous menstruum, which he boasts Paracelsus and himself to have been possessed of, and which he usually calls ALKAHEST.

LATH, in *Building*, a long, thin, narrow slip of wood, nailed on the rafters of a roof, in order to sustain the covering. These are what Festus calls *imbrices*; in other Latin writers they are denominated *tegulæ*, and by Gregory of Tours, *ligneræ*.

Laths

Laths are divided into three kinds, with regard to the different woods they are made of; viz. *heart of oak laths*, *fap laths*, and *deal laths*; the two laſt are uſed only for ceiling and partitioning, and the firſt only for tiling.—*Laths* are alſo diſtinguiſhed, with regard to their length, into *five* feet, *four* feet, and *three* feet *laths*: though the ſtatute allows but of two lengths; viz. thoſe of five feet, and of three; each of which are to be an inch and half in breadth, and half an inch in thickneſs.

LATH-*bricks*, a particular ſort of *bricks* made in ſome parts of England of twenty-two inches long, and ſix inches broad, which are uſed in the place of laths, or ſpars, ſupported by pillars in *oaſts*, for the drying of malt. This is an excellent contrivance; for, beſide that they are not liable to fire as the wooden-*laths* are, they retain the heat vaſtly better; ſo that being once heated, a very ſmall quantity of fire will keep them ſo. Plot's Oxfordſhire, p. 257. See BRICK.

LATHE, or LEATHE, a very uſeful engine for the turning of wood, ivory, and other materials.

The invention of the *lathe* is very ancient: Diodorus Siculus ſays, the firſt who uſed it was a grandſon of Dædalus, named Talus. Pliny aſcribes it to Theodore of Samos; and mentions one Thericlis, who rendered himſelf very famous by his dexterity in managing the *lathe*.

The Greek and Latin authors make frequent mention of the *lathe*; and Cicero calls the workmen who uſed it *vaſcatarii*. It was a proverb among the ancients, to ſay a thing was formed in the *lathe*, to expreſs its delicacy and juſtneſs.

The *lathe* is compoſed of two wooden cheeks or ſides, parallel to the horizon, having a groove, or opening, between; perpendicular to theſe are two other pieces, called *poppets*, made to ſlide between the cheeks, and to be fixed down at any point, at pleaſure.

Theſe have two points, between which the piece to be turned is ſuſtained; the piece is turned round, backwards and forwards, by means of a ſtring put round it, and faſtened above to the end of a pliable pole, and underneath to a treddle, or board moved with the foot: there is alſo a reſt which bears up the tool, and keeps it ſteady.

As it is the uſe and application of this inſtrument that makes the greateſt part of the art of turning, we refer the particular deſcription thereof, as well as the manner of applying it in various works, to that head. See TURNING.

LATHE, in *Law*. See LEYHE.

LATHRÆA, in *Botany*, the name given by Linnæus to the plant called by Tournefort *clandeſtina*. This, in the Linnæan ſyſtem of botany, is alſo a diſtinct genus of plants of the *didynamia angioſpermia* claſs; the characters of which are, that the cup is compoſed of one leaf, ſtanding erect, and repreſenting a bell, with its rim deeply divided into four ſegments; the flower is compoſed of a ſingle petal, in form of a tube, longer than the cup, with a gaping and bellied mouth; the upper lip of the flower is hooded, and is broad and concave, with a narrow crooked extremity; the under one is ſmaller, crooked, obtuſe, and divided into three parts; the ſtamina are two pointed filaments, of the length of the flower, hid beneath the upper lip; the antheræ are two on each filament, obtuſe above, and narrower below; the piſtil has a roundiſh germen, a thread-like ſtyle of the ſame length with the ſtamina, and placed in the ſame manner with them, and a truncated ſtigma; the fruit is a roundiſh, obtuſe, but pointed capſule, containing one cell, having two valves, and is very elaſtic.

LATHREVE, LEIDGREVE, or TRITHINGREVE, was an officer under the Saxon government, who had authority over a third part of the county; and whoſe territory was therefore called trithing, otherwiſe a leid or leithin, in which manner the county of Kent is ſtill divided; and the rapes in Suſſex ſeem to anſwer to the ſame. As to the juriſdiction of this officer, thoſe matters that could not be determined in the hundred court, were thence brought to the trithing; where all the principal men of the three or more hundreds being aſſembled by the *lathreve*, or *trithingreve*, did debate and decide it; or if they could not, then the *lathreve* ſent it up to the county court, to be there finally determined.

LATHYRIS, in *Botany*, a name given by many authors to a ſpecies of tithymal, or SPURGE, commonly known by the name of *tithymalus latifolius*, the broad-leaved ſpurge, and called by ſome alſo CATAPUTIA.

LATHYRUS, in *Botany*. See *Chickling* VETCH.

LATIAR, a feaſt, or ceremony, inſtituted by Tarquinius Superbus, in honour of Jupiter Latiaris or Latialis.

Tarquin, having made a treaty of alliance with the Latins, propoſed, in order for perpetuating it, to erect a common temple, where all the cities, the Romans, Latins, Hernici, Volſci, &c. ſhould aſſemble themſelves every year, hold a kind of fair, exchange merchandizes, feaſt, ſacrifice, and make merry together. Such was the inſtitution of the *Latiar*. The founder only appointed one day for this feaſt; the firſt conſul added another to it, upon concluding the peace with the Latins; and a third was added, after the people who had retired to the Mons Sacer were returned to Rome; and a fourth, after appeaſing the ſedition riſed on occaſion of the plebeians aſpiring to the conſulate.

Theſe four days were called the *Latin* feriæ; and all things done during the courſe of the feriæ, as feaſts, ſacrifices, offerings, &c. were called *Latiares*.

LATIBULUM, a word uſed by ſome medical writers for the ſomes, or latent matter, which is the occaſion of ſevers and other diſorders.

LATICLAVIUM, or LATUS-CLAVUS, a garment which was a diſtinction and dignity among the Romans, contradiſtinguiſhed from the anguſticlavium.

The *lati-clavium* was a kind of tunic or long coat, faced with one or two ſlips of purple, applied lengthwiſe to the two ſides of the tunic.

In the *latus-clavus* theſe ſlips were pretty broad, and in the anguſtus-clavus narrower; though there is nothing about which the learned differ more than the difference between theſe two habits.

There were buttons ſet on the *latus-clavus*, which appeared like the heads of large nails; whence ſome think it took its name.

The ſenators, prætors, and the chief magiſtrates of colonies and municipal cities, had a right to wear it. The robe called prætexta was worn over the *latus-clavus*. When the prætor pronounced ſentence of death, he put off the prætexta; but retained the *latus-clavus*.

LATIN, a dead language, firſt ſpoken in Latium, and afterwards at Rome, and ſtill uſed in the Romiſh church, and among men of letters.

Some authors rank the *Latin* among the number of original languages, but by miſtake: it is formed principally from the Greek, and particularly from the Æolic dialect of that tongue; though it has a great number of words which it borrowed from the languages of the Etruſci, Oſci, and other ancient people of Italy; and foreign commerce and wars, in courſe of time, added a great many more.

The *Latin* is a ſtrong, nervous language, perfectly ſuitable to the character of the people who ſpoke it. The Romans were engaged in wars and commotions, foreign and domeſtic, which for ſeven hundred years engroſſed all their thoughts. Hence, therefore, ſays the ingenious Mr. Harris, their language became like their ideas, copious in all terms, expreſſive of things political, and well adapted to the purpoſes both of hiſtory and popular eloquence. But the Romans were no philoſophers; and hence the unfitneſs of their language to this ſubject; a defect, which even Cicero is compelled to confeſs, and more fully makes appear, when he writes philoſophy himſelf, from the number of terms he is obliged to invent. Harris's Hermes, p. 411, &c.

The *Latin* is more figurative than the Engliſh, leſs pliant than the French, leſs copious than the Greek, leſs pompous than the Spaniſh, leſs delicate than the Italian, but cloſer and more nervous than any of them.

For a while the *Latin* tongue was confined almoſt wholly within the walls of Rome; nor would the Romans allow the common uſe of it to their neighbours, or to the nations they ſubdued. Cicero obſerved, that even in his time, Greek was uſed almoſt among every people, but the *Latin* only confined to a very narrow compaſs. By degrees they were brought to grant the uſe of it as a favour; and, in time, became ſenſible of the neceſſity there was of its being generally underſtood, for the convenience of commerce: and, accordingly, uſed their utmoſt endeavours, that all the nations ſubject to their empire ſhould be united by one common language: ſo that at length they impoſed that as a law which they had before granted as a favour.

After the tranſlation of the ſeat of the empire from Rome to Conſtantinople, the emperors of the Eaſt, being always deſirous of retaining the title of Roman emperors, appointed the *Latin* to be ſtill retained in uſe, both in their reſcripts and edicts, as appears by the conſtitutions of the eaſtern emperors, collected in the Theodoſian Code; but at length the emperors, neglecting the empire of the Weſt, abandoned all care of the *Latin* tongue, and allowed their judges to paſs ſentence in Greek; and, accordingly, we find the emperor Juſtinian's Novels are compoſed in Greek.

Charlemagne, coming to the empire of the Weſt, appointed the law-proceedings in ſovereign courts to be made in *Latin*; and the notaries were to draw their acts

and inſtruments in ſame tongue: this practice continued a long time through a great part of Europe; but at length it gave way, and the French took place of the *Latin*, not only in France, but, in ſome meaſure, in England too; and the reaſon given for it was, that abundance of difficulties aroſe about the underſtanding of *Latin* terms.

The *Latin*, however, was prodigiouſly degenerated and corrupted, before it came to be laid aſide. The incurſions of the Goths and Vandals into Italy brought an inundation of foreign words and phraſes into it; inſomuch that Valla and Naud call Boethius the laſt *Latin* author. By command of Theodoric, king of the Goths, it was the hard fate of this worthy man, ſays Mr. Harris, to ſuffer death; with whom the *Latin* tongue, and the laſt remains of Roman dignity, may be ſaid to have ſunk in the weſtern world. But that was not all; when it once got into the courts of juſtice, it was ſtill worſe handled; till, at laſt, being introduced amongſt the monks, and become the common language of miſſals and breviaries, it was debauched to that degree, that it was almoſt become ſcandalous to uſe it.

In this condition it was found at the time of the Reformation, when Vives, Eraſmus, &c. began to open the way for its recovery; ſince which time monkiſh Latinity has been declining, and all endeavours have been uſed to retrieve the pure language of the Auguſtan age.

It was ſaid of cardinal Bembo, that he would never read the breviary for fear of corrupting his fine *Latin*.

LATIN *bible*. See BIBLE.

LATIN *character*. See CHARACTER.

LATIN *church*, is a term uſed for the *Romiſh* or *weſtern* CHURCH, by way of oppoſition to the GREEK *church*.

LATINÆ *feriæ*. See FERIÆ.

LATION, is uſed by ſome for the tranſlation or motion of a body from one place to another.

LATISSIMUS *dorſi*, in *Anatomy* a muſcle, ſo called from its ſhape, covering almoſt the whole back.

It has a thin, broad, tendinous beginning, which comes from the poſterior part of the ſpine of the ilium, from the ſuperior ſpines of the os ſacrum, from all the ſpines of the vertebræ of the loins, and from the ſeven lower of the thorax; it paſſes by the inferior angle of the ſcapula, from which ſome of its fleſhy fibres ſometimes ariſe; and is inſerted with the teres major, by a ſtrong and broad tendon, with which it pulls the arm downwards.

It is alſo called *ani ſcalptor*, becauſe it carries the arm to the anus. See *Tab. Anat. (Myol.) fig.* 6. *n.* 28.

LATITAT, in *Law*, a writ, whereby all men in perſonal actions are called originally to the king's bench.

It has this name, as ſuppoſing the defendant lurks, lies hid, and cannot be found in the county of Middleſex, to be taken by bill; but is gone to ſome other county, to the ſheriff whereof this writ is directed.

LATI-TENDINIS *muſculus*, in *Anatomy*, a name given by Spigelius and others to a muſcle, called by Winſlow *muſculus faſciæ latæ*, and by Albinus the *muſculus cruæus femoris*. See MEMBRANOSUS.

LATITUDE, LATITUDO, in *Geography*, the diſtance of a place from the equator; or an arch of the meridian, intercepted between the zenith of the place, and the equator. Hence *latitude* is either *northern* or *ſouthern*, according as the place, whoſe *latitude* is ſpoken of, is on this or that ſide of the equator. Thus London is ſaid to be in 51 degrees 32 minutes northern *latitude*.

Circles parallel to the equator are called *parallels of latitude*, becauſe they ſhew the *latitudes* of places by their interſection with the meridian.

If through the poles of the world we conceive innumerable great circles drawn, theſe are called *ſecondaries* of the equator; and, by their help, the poſition of every point, either on earth, or in the heavens, with regard to the equinoctial, [that is, the *latitude* of any point], is determined. See SECONDARY.

One of theſe ſecondaries, paſſing through any place on the earth's ſurface, is called the meridian of that place; and on it the *latitude* of that place is meaſured. See MERIDIAN.

The *latitude* of a place, and the elevation of the pole of that place above the horizon, are terms uſed indifferently for each other, becauſe the *latitude*, and the elevation of the pole, are always equal.

This will appear from *Tab. Geography. fig.* 3.—where the circle H Z Q repreſents the meridian, H O the horizon, Æ C Q the equator, Z the zenith, and P the pole.

Here the *latitude* of the place, or its diſtance from the equator, is the arch Z Æ; and the elevation of the pole, or its diſtance from the horizon, the arch P O.—Now the arch P Æ between the pole and the equator, is a quadrant of a circle; and the arch Z O, from the zenith to the horizon, is likewiſe a quadrant, therefore the two arches P Æ, and Z O, muſt be equal; and taking away the arch Z P, which is common to both, there will remain the arch Z Æ, equal to the arch P O; that is, the latitude of the place equal to the elevation of the pole above the horizon. Hence we have a method of meaſuring the circumference of the earth, or of determining the quantity of a degree on its ſurface; for by going directly northward, or ſouthward, till the pole be elevated one degree more or leſs, and then meaſuring that interval accurately, we ſhall have the number of miles in a DEGREE of a great circle of the earth's globe.

The knowledge of the *latitude* of the place is of the utmoſt conſequence, in geography, navigation, and aſtronomy; the methods of determining it, both at ſea and land, are as follow.

The altitude of the pole, it has been already ſhewn, is always equal to the *latitude*; for which reaſon the *latitude* might be beſt found by obſerving the pole's height; but as the pole is only a mathematical point, and no ways to be obſerved by our ſenſes, its height cannot be determined in the ſame manner as that of the ſun and ſtars, &c. for which reaſon another manner has been contrived.

In order to this, a meridian line is firſt drawn; the method of doing which, ſee under the word MERIDIAN. Place a quadrant on this line, ſo that its plane may be in the plane of the meridian; then take ſome ſtar near the pole, v. gr. the pole-ſtar (which never ſets), and obſerve both its greateſt and leaſt altitude.

Let the greateſt, v. gr. be SO (*Tab. Geography, fig.* 3.) and the leaſt PO; the half of the difference of which PS, or Ps, deducted from the greateſt altitude SO, or added to the leaſt PO, will give PO, the altitude of the pole above the horizon, which is equal to the *latitude* of the place.

The *latitude* may alſo be found by having the ſun's, or a ſtar's, declination, and meridian altitude, taken with a QUADRANT, or aſtrolabe. The method is this:

Obſerve the meridian diſtance of the ſun from the vertex or zenith, which is always the complement of his meridian altitude; correct for the DIP of the horizon and REFRACTION; and add to this the ſun's declination, when the ſun and the place are on the ſame ſide of the equator; or ſubtract the declination, when they are of different ſides; the ſum, in the former caſe, and the difference in the latter, will be the *latitude* required. But when the declination of the ſun is greater than the *latitude* of the place, which is known from the ſun's being nearer to the elevated pole, than the vertex of the place is, as it frequently happens in the torrid zone, then the difference between the ſun's declination, and his zenith diſtance, is the *latitude* of the place.

If the ſun or ſtar have no declination, but move in the equinoctial that day, then the elevation of the equator will be equal to his meridian altitude; and, conſequently, his meridian altitude is the complement of the *latitude* to 90.

This latter method is beſt accommodated to the uſes of navigation, as being practicable at ſea; but the former method preferable at land. But circumſtances frequently occur at ſea, which render it impoſſible to obſerve the meridian altitude of a celeſtial object: we ſhall, therefore, ſubjoin ſome of the readieſt and moſt approved practical methods of determining the *latitude* in caſes of this kind.

For this purpoſe take one, two, or more altitudes of the ſun in the forenoon, noting by a watch the time of each; and if the meridian altitude cannot be obtained, take one, two, or more altitudes of the ſun in the afternoon, noting alſo the times by the watch: if poſſible, let the morning altitudes, if 3, be taken at equal intervals of time; if not, let the afternoon obſervations be taken at the ſame altitudes with the morning ones. Then,

1. If one morning and one afternoon obſervation are taken, when the ſun has the ſame altitude, and the name of the elevated pole is known, to find the elevation, or *latitude*. To twelve hours add the morning and afternoon times ſhewn by the watch, and half the ſum gives the time by the watch, when the ſun was on the meridian of that place, ſuppoſing no change of declination. Let the interval of time between that noon, and the time of either obſervation, be turned into degrees and minutes for the hour-angle, which is ſuppoſed to be leſs than 90°, becauſe the obſervations are within ſix hours of noon: to the logarithmic coſine of the hour-angle add the logarithmic tangent of the ſun's diſtance from the elevated pole, their ſum is the logarithmic tangent of the firſt arc, of the ſame kind with the polar diſtance: add the arithmetical complement of the logarithmic coſine of the polar diſtance, the logarithmic ſine of the altitude, and the logarithmic coſine of the foreſaid firſt arc, their ſum is the logarithmic coſine of a ſecond arc, always leſs than 90°: the difference of the firſt and ſecond arcs is the complement of the required *latitude*, when the firſt arc exceeds the ſecond; otherwiſe the difference is the *latitude*.

2. When three zenith diſtances between the limits of 30°

and 70° are taken within an hour of noon, at equal intervals of time between 15 and 30 minutes. If the firſt and third zenith diſtances are equal, the middle one is the meridian zenith diſtance. If the two firſt or two laſt zenith diſtances are equal, from one of theſe take one eighth of the difference between it and the greater zenith diſtance, and the remainder is that on the meridian. When the three zenith diſtances are unequal, let the difference between the greateſt and middle be called A, the difference between the greateſt and leaſt be called B, the difference between B and 4 A be called C, and the difference between B and C be called D: then $\frac{C^2}{4B}$, will give a number of minutes, which, ſubtracted from the greateſt zenith diſtance, leaves the meridian zenith diſtance.

3. When three zenith diſtances, between the limits of 30° and 70° are taken within an hour and half of noon, at unequal intervals of time: let the difference in minutes between the greateſt and middle zenith diſtances be called A, and the interval of time *a*; the difference between the firſt and laſt be called B, and the correſponding interval of time *b*. From the logarithm of the difference of the products A*b* and B*a*, take the logarithm of *b*, and call the remainder N; then add the log. of N, twice the log. of the difference between *a* and $\frac{1}{2}$ *b*, the arithmetical complement of the difference between *a* and *b*, and the arithmetical complement of the log. of *a*, and the ſum will give a log. which call M. Find the numbers correſponding to N, M, and $\frac{1}{2}$ B, and call their ſum E. From 4E take B, and call the remainder C, and B—C call D. Then the log. of 4 D, taken from twice the log. of C, gives the logarithm of the correction in minutes; and the greateſt zenith diſtance diminiſhed by the correction, will give the meridian zenith diſtance.

4. When three altitudes are taken at equal intervals of time, at any diſtance from noon: find the natural ſines of the three given altitudes; call the difference between the firſt and third, D; and between the ſecond and third F. Let E=D+2F, when the degrees of the third altitude fall between thoſe of the firſt and ſecond; otherwiſe let E=D—2F. Add the log. cotang. of half one interval of time in degrees, the log. of E, and the ar. co. log. of D, each in numbers; and their ſum is the logarithmic tangent of an angle A, or of its ſupplement, if the firſt altitude exceeds the third; convert the angle A into time; to A add one interval; then the difference between this ſum and ſix hours will ſhew the time from noon, when the laſt obſervation was made. Hence, by the intervals, the other times are known relative to the noon of the place of obſervation. Add together the ar. co. log. coſine of A, the ar. co. log. ſine of one interval obſerved, and the log. of D; and their ſum is the log. of a number B; to the log. of which add twice the logarithmic ſine of half the leaſt time from noon; ſeek the number, and add it to the natural ſine of the greateſt altitude, which will give the natural ſine of the meridian altitude. The number B, leſſened by the natural ſine of the meridian altitude, gives the natural ſine of the midnight depreſſion: then the half ſum and the half difference, being taken, of the degrees and minutes anſwering to the ſines of the meridian altitude and midnight depreſſion, will give the *co-latitude* and declination. If the zenith falls between the equator and the ſun, the half ſum is the co-declination, and the half difference is the *latitude*.

5. When three altitudes are taken at unequal intervals of time: call the interval between the firſt and third times M, between the firſt and ſecond, *m*, between the ſecond and third, *n*, and convert M, *m*, *n*, into degrees; find the natural ſines of the three obſerved altitudes; call the difference between the firſt and third D, and between the ſecond and third F; add the log. ſines of $\frac{1}{2}m$ and $\frac{1}{2}n$, for the log. of $\frac{1}{2}$ A; and the log. coſine of $\frac{1}{2}m$ to the log. ſine of $\frac{1}{2}n$ for the log. of $\frac{1}{2}$ B: add the ar. co. log. of D, the log. of F, and the log. ſine of $\frac{1}{2}$ M, for the log. of $\frac{1}{2}$ C: take the difference between $\frac{1}{2}$ B and $\frac{1}{2}$ C, and call it $\frac{1}{2}$ E; or let $\frac{1}{2}$ E be the ſum of $\frac{1}{2}$ B and $\frac{1}{2}$ C, when the degrees in the third altitude fall between thoſe of the firſt and ſecond. From the log. of $\frac{1}{2}$ E take the log. of $\frac{1}{2}$ A, the remainder, adding 10 to the index, is the logarithmic tangent of an arc G; or of its ſupplement, when the firſt altitude exceeds the ſecond. Take the difference between G, and the complement of $\frac{1}{2}$ M, the remainder is an arc H, ſhewing the time from noon when the laſt altitude was taken: hence the other times are known. Add the ar. co. log. coſine of G, the ar. co log ſine of $\frac{1}{2}$ M, and the log. of D, their ſum is the log. of a number I: to log. of I add twice the log. ſine of $\frac{1}{2}$ H for the log. of K, which, added to the natural ſine of the third altitude, will give the natural ſine of the meridian altitude; and the number I, diminiſhed by the natural ſign of the meridian altitude, gives the natural ſine of the midnight depreſſion; the half ſum and half difference of the degrees ſhewing the meridian altitude and midnight depreſſion, will give the *co-latitude* and declination, or co-declination and *latitude*, when the zenith falls between the ſun and the equator.

6. When two altitudes of the ſun, the interval of time between the two obſervations, the ſun's declination, and the *latitude* by dead reckoning, are given; to find the true *latitude*. 1. Convert the interval of time into degrees, and take its half; take alſo the half ſum and half difference of the two altitudes. 2. Add the five following logarithms; viz. log. coſine of the half ſum of the two altitudes; log. ſine of the half difference of the two altitudes; ar. co. log. ſine of the half interval; ar. co. log. coſine of the declination, and ar. co. log. coſine of the *latitude* by account; their ſum is the log. ſine of an arc. 3. Half the difference between this arc and the half interval, is half a time from noon. 4. Then add the log. coſine of the declination, log. coſine of the *latitude* by account, and twice the log. ſine of half a time from noon, in degrees: the number anſwering to the log. of this ſum, doubled, is the correction; which being added to the natural ſine of the greateſt obſerved altitude, gives the natural ſign of the meridian altitude, whence the *latitude* is known. In order to know whether the *latitude* thus found be accurate, make a ſecond operation: thus, to the ſum of the firſt four logs. uſed in the ſecond article of the preceding operation, add the ar. co. log. coſine of the *latitude*, found by art. 4. the ſum is the log. ſine of an arc. Proceed by the third and fourth articles for a corrected *latitude*; and if it comes out the ſame, within a minute or two, as that found above, it may be eſteemed the true *latitude*; or, if the difference between the reſults of the two operations do not exceed about $\frac{1}{4}$th of the difference between the *latitude* aſſumed, and that firſt found, the laſt reſult may be accounted ſufficiently correct. But if the difference is much greater than the ſaid $\frac{1}{4}$th part, then a third operation with the laſt found *latitude* will generally give the *latitude* exact enough. When the *latitudes*, found by the firſt and ſecond operations, have one greater and one leſs than the *latitude* by account, or if they differ by a degree or more, make a third operation with the half ſum or mean of theſe two *latitudes*; and if the *latitude* found differs from the ſaid mean, then halt their ſum will generally give the *latitude* very near the truth. When both obſervations are made in the forenoon, or both in the afternoon, the half interval is half the difference of the times from noon, and the firſt found arc is half the ſum of the times from noon: but when the obſervations occur, one before and the other after noon, the $\frac{1}{2}$ interval is the $\frac{1}{2}$ ſum, and the firſt found arc is the half difference of the times from noon; the $\frac{1}{2}$ difference added to the $\frac{1}{2}$ ſum, gives the time of the obſervation fartheſt from noon; and the $\frac{1}{2}$ difference taken from the $\frac{1}{2}$ ſum, gives the time of the obſervation neareſt to noon. The times of obſervation are beſt when taken to ſeconds, or at leaſt to quarters or thirds of a minute of time: they are alſo beſt when taken between the times of 9 h. A. M. and 3 h. P. M. and the interval between them ſhould not exceed five hours, nor be much leſs than the time from noon at the taking of the greateſt altitude; or, in general, the interval ſhould not be much leſs than about $\frac{1}{4}$ of an hour.

Mr. John Douwes of Amſterdam contrived, in 1740, ſolar tables for the ſolution of this problem, which were publiſhed in 1759. Dr. Pemberton communicated to the Royal Society the whole conſtruction of theſe tables, &c. in a paper publiſhed in the Phil. Tranſ. vol. li. art. 81. But the preceding ſolution requires no other tables than are found in the common books of navigation; though the ſolar tables, ſuch as may be found in the Nautical Almanack for 1771, may ſave ſome time in the computation. See the principles on which the preceding problems are founded, mathematically demonſtrated, and their uſe illuſtrated by examples, in Robertſon's Elem. of Navigation, book v. and book ix. See alſo Nautical Almanack for 1771.

Mr. Richard Graham contrived an inſtrument for taking the *latitude* of a place at any time of the day. For this purpoſe, to the meridian of a globe properly divided, he adapts a piece of a like meridian, called the beam-compaſs, divided in the ſame manner, and ſliding under the meridian: to theſe circles, and to five minutes of their degrees, are fitted two ſliding Vernier's ſcales, in ſuch a manner, that a wire fixed at 0 degree at the center or end of the beam-compaſs, ſhall paſs through a hole at the beginning of the diviſions of one Vernier, which is to ſlide on the meridian, that wire ſerving as the center of motion of the beam-compaſs, when the Vernier is

ſkrewed

screwed to the meridian: the other Vernier is to slide on the beam compass, and carry with it a pointer, or index, at the beginning of its divisions.

With this instrument the problem is thus solved. At the time of the first observation, let the sun's bearing be also observed, and take the difference between the rhumb on which the sun was observed, and the rhumb on which the ship steered between the observations: then say,

As radius is to the cosine of that difference of rhumbs; so is the distance run between the observations, to the minutes of correction to be applied to the first zenith distance, and is to be added when the ship sails from the sun, otherwise it is to be subtracted.

Then slide the Vernier's scale on the meridian to the given declination, and the Vernier on the beam-compass to the first zenith distance as corrected, and let these scales be fixed by their screws: rectify the globe for noon, turn it till the hour-index points at the time of the first observation, there hold the globe fast, and move the beam-compass on its center, nearly into the azimuth of the sun at that observation, and describe an arc on the globe with the pointer of the Vernier; slide the Vernier on the beam-compass to the second observed zenith distance; turn the globe (the proper way) till the hour-index points at the time of the second observation, there hold the globe fast, and with the beam-compass cut the former arc, their intersection will shew the place of the ship at the time of the second observation: bring the meridian over that point, and the *latitude* is found; also the hour-index will point at the true time of the day when the last observation was made. Phil. Trans. N° 435. or abridg. vol. viii. p. 371.

LATITUDE, in *Astronomy*, is the distance of a star or planet from the ecliptic.

Or, it is an arch of a great circle, TS *(Tab. Astron. fig. 14. n. 2.)* intercepted between the center of the star S, and the ecliptic EL, and perpendicular thereto.

Through the poles of the ecliptic are supposed to pass an indefinite number of great circles, cutting the ecliptic at right angles, called *circles of latitude*, or secondaries of the ecliptic; by means of which every star, and point of the heavens, is reduced to the ecliptic, and has its place in regard thereto determined; the *latitude* of a star being an arch of one of these secondaries, intercepted between that star, and the point where it intersects the ecliptic.

In which the *latitude* differs from the *declination*, which is the distance of a star from the equator, towards one of the poles of the world.

So that the geographical *latitude* is the same thing with the astronomical declination; and the astronomical *latitude* a quite different thing.

The *latitude* of a planet is an angle, as PTR *(Tab. Astronomy, fig. 26.)* under which a planet's distance from the ecliptic PR is seen on the earth.

The sun never has any *latitude*, but the planets have; for which reason, in the common sphere, the zodiac has some breadth. The ancients only allowed six degrees on each side the ecliptic, but the moderns have extended it to nine.

When they have no *latitude*, they are said to be in the *nodes* of the ecliptic, or in the intersection of their orbit with that of the sun; and in this situation it is that they eclipse, or are eclipsed by, the sun.

LATITUDE, *circle of*, is a great circle, MST *m*, passing through the poles of the ecliptic. See CIRCLE.

LATITUDE *of the moon, north ascending*, is when she proceeds from the ascending node towards her northern limit, or greatest elongation.

LATITUDE, *north descending*, is when the moon returns from her northern limit to the descending node.

LATITUDE, *south descending*, is when she proceeds from the descending node to her southern limit.

LATITUDE, *south ascending*, is when she returns from her southern limit to her ascending node.

And the same holds good of the other planets. See ASCENDING and DESCENDING.

LATITUDE, *heliocentric, of a planet*, is its distance from the ecliptic, such as it is seen from the sun.

This when the planet comes to the same point of its orbit, is always the same, and unchangeable.

LATITUDE, *geocentric, of a planet*, is the distance of the planet from the ecliptic, as it is seen from the earth.

This, though the planet be in the same point of its orbit, yet is not constantly the same, but alters according to the position of the earth, in respect to the planet. See HELIOCENTRIC, and GEOCENTRIC.

Dr. Halley has some considerations, in the Philosophical Transactions, which make it probable, the *latitudes* of some of the principal fixed stars, particularly Palilicium, Sirius, and ARCTURUS, alter in time; whence it may be argued, the rest likewise alter, though the variation may be less conspicuous in these, because they are supposed at a greater distance from us.

LATITUDE, *difference of*, is an arc of the meridian, or the least distance of the parallels of *latitude* of two places; and it is found when these have the same name, by subtracting the lesser *latitude* from the greater; and when they have contrary names, by adding them together.

LATITUDE, *parallax of*. See PARALLAX.

LATITUDE, *refraction of*. See REFRACTION.

LATITUDINARIAN, among *Divines*, denotes a person of moderation, with regard to religious opinions, who believes there is a latitude in the road to heaven, which may admit people of different persuasions. This name was given by way of distinction to those excellent persons in England, who, about the middle and towards the close of the last century, endeavoured to allay the contests that prevailed between the more violent episcopalians on the one hand, and the more rigid presbyterians and independents on the other, with respect to the forms of church government and public worship, and also between the Armenians and Calvinists, with respect to certain religious tenets. Many of them were zealously attached to the forms of ecclesiastical government and worship that were established in the church of England, and they recommended episcopacy with all their eloquence; but they did not consider it as of divine institution, and absolutely necessary to the constitution of a Christian church; and therefore they maintained, that those who followed other forms of government and worship, were not, on that account, to be excluded from their communion, or to forfeit the title of brethren. Others had no great liking for the liturgy or ceremonies, or, indeed, the government of this church, but yet for the sake of peace and order conformed. As to the doctrinal part of religion, they took the system of the famous Episcopius for their model, and, like him, reduced the fundamental doctrines of Christianity, i. e. those doctrines, the belief of which is necessary to salvation, to a few points. By this manner of proceeding they shewed that neither the episcopalians, who, generally speaking, embraced the sentiments of the Arminians, nor the presbyterians and independents, who as generally adopted the doctrine of Calvin, had any reason to oppose each other with such bitterness and animosity, since the subjects of their debate were matters of indifference with respect to salvation, and might be variously explained and understood, without any prejudice to their eternal interests.

The chief leaders of these *Latitudinarians* were Hales and Chillingworth: to them may be added the respectable names of More, Cudworth, Gale, Whitchcot, Wilkins, and Tillotson. The first fruits of their charitable zeal were the odious appellations of atheists, deists, and Socinians, liberally bestowed upon them by the Roman catholics, and the more rigid of the protestant contending parties. However, they were afterwards raised to the first dignities of the church, and deservedly held in general esteem. And at this time the church of England is chiefly governed by *Latitudinarians* of this kind: and the spirit of moderation and mutual charity has generally prevailed, with that of liberal enquiry, among the various sects and denominations of Christians. Mosheim's Eccl. Hist. vol. iv. p. 535, &c. 8vo. and Birch's Life of Tillotson, p. 407. See COMPREHENSION.

LATOMIA, *Λατομια*, derived from the Greek *λας, stone*, and *τεμνω, I cut*, properly signifies a QUARRY, or place where stones are dug.

These were anciently used as gaols for criminals. Dionysius had a place of this kind dug in a rock near Syracuse, where an infinite number of people were shut up. Cicero reproaches Verres with imprisoning Roman citizens in *latomiæ*; so that *latomia* became a general name for a prison; and the prisoners inclosed in them were called *latomiarii*.

LATONA, in *Mythology*, a goddess of paganism, whose history is very obscure. Hesiod makes her the daughter of Titan Cœus and Phœbe, his sister. The fable adds, that Apollo and Diana were her offspring by Jupiter, and that they advanced her to the rank of celestial deities in spite of Juno. According to Herodotus, she was an Egyptian deity, and was worshipped at Buto in Egypt. The inhabitants of Delos erected a temple for her; but that at Argos was the most magnificent, and celebrated for her statue, executed by Praxiteles. *Latona*, Venus, and Diana, were the three goddesses most in veneration among the Roman women.

LATRIA, *Λατρια*, in *Theology*, a religious worship, due only to God.

The Romanists say, "They honour God with the wor-"ship of *latria*; and the saints with the worship of *du-*"*lia*:" but the terms, however distinct, are usually confounded.

The worship of *latria*, besides its inner characters, has

its external marks to diſtinguiſh it; the principal whereof is ſacrifice, which cannot be offered to any other but God himſelf, as being a ſolemn acknowledgement, or recognition, of the ſovereignty of God, and our dependence on him.

M. Daillé ſeems to own, that ſome of the fathers of the fourth century allowed the diſtinction between *latria* and *dulia*. See ADORATION and WORSHIP.

LATTIMO, in the *Glaſs-trade*, a name for a fine milk-white glaſs. There are ſeveral ways of making it, but the beſt of all is this: take four hundred weight of cryſtal frit, and ſixty pounds of calcined tin, and two pounds and a half of prepared manganeſe; mix theſe well with the frit, and ſet them in a pot in a furnace to melt and refine. At the end of eighteen hours this will be purified; then caſt it into water, purify it again afterwards in the furnace, and make a proof of it. If it be too clear add fifteen pounds more of calcined tin; mix it well with the metal, and let it ſtand one day to purify; it will then be of a whiteneſs ſurpaſſing even that of ſnow, and is fit to work into veſſels. Neri's Art of Glaſs, p. 98. See GLASS.

LATTIN, or LATTEN, a name by which we uſed to call the plates of iron covered with tin, and now uſually called *tin*, of which our mugs, and ſuch other things are made. The principal part of the work is to prepare the leaves, beat out to a proper thinneſs, ſo as that they ſhall readily receive the tin; for if there be but the ſmalleſt particle of duſt on them, or only the ſlighteſt ruſt in any part, the tin will never fix there.

This ſmoothing of the plates is effected by ſteeping them in acid water, till the ſurface is a little preyed upon by it, and then they are ſcowered with ſand, which makes them very ſmooth and fine. By this means a woman cleans more plates in an hour, than the moſt expert workman can do otherwiſe in many days. Mr. Reaumur, to whom the world owes the diſcovery of this proceſs, mentions ſeveral waters, any one of which will ſucceed, but the Germans themſelves uſe nothing but common water, made eager with rye. This they make a great ſecret of, but the preparation is very eaſy. After they have ground the rye groſsly, they leave it to ferment in common water for ſome time; and they are thus ſure of a ſharp and eager menſtruum, excellently fitted for their purpoſe. With this liquor they fill certain troughs, or tuns, and into theſe they put ſeveral bundles of the plates of iron: And to make the liquor be more eager, and act the better on them, they keep it in ſtoves, where it has little air, and is kept warm with ſmall charcoal fires.

There are ſeveral other ways of making iron ruſt, as keeping it in a moiſt cellar, expoſing it to the dew, ſprinkling it with ſimple water, or, which is ſtill better, with water in which ſal armoniac has been diſſolved, ſeveral times a day: and in thoſe countries where the pyrites is common, the vitriolic waters, which partake of it, will do it very well. This water may be prepared at little or no expence, only by heaping up large quantities of the pyrites, and letting it moulder in the air, then putting it into common water, and making a lixivium of it.

Whichever method of ruſting the plates be uſed, it is always neceſſary to ſcower them with ſand as ſoon as it is done; and when they are thus cleaned, they muſt be immediately plunged into water, to prevent their ruſting again, and they are to be left in this water till the inſtant in which they are to be tinned, or in the language of the workmen, *blanched*. The people, employed in this part of the operation, are called *blanchers*; and the others, who aſſiſt at the cleaning the plates, the *ſealers*. The blancher makes as great a ſecret of his art, as the ſealer does of his; and it was with great difficulty that Mr. Reaumur obtained it. The manner of doing it is this.

They fuſe the tin in a large iron crucible, which has the figure of an oblong pyramid with four faces, of which two oppoſite ones are leſs than the two others. The crucible is heated only from below, its upper part being luted with the furnace all round. The crucible is always deeper than the plates, which are to be tinned, are long; they always put them in downright, and the tin ought to ſwim over them. To this purpoſe artificers of different trades prepare plates of different ſhapes, but Mr. Reaumur thinks them all exceptionable. But the Germans uſe no ſort of preparation of the iron, to make it receive the tin, more than the keeping it always ſteeped in water till the time; only when the tin is melted in the crucible, they cover it with a layer of a ſort of ſuet, which is uſually two inches thick, and the plate muſt paſs through this before it can come to the melted tin. The firſt uſe of this covering is to keep the tin from burning; as if any part ſhould take fire, the ſuet would ſoon moiſten it, and reduce it to its primitive ſtate again. The blanchers ſay, this ſuet is a compounded matter. It is indeed of a black colour, but Mr. Reaumur ſuppoſed that to be only an artifice to make it a ſecret, and that it is only coloured with ſoot, or the ſmoke of a chimney; but he found it true ſo far, that the common unprepared ſuet was not ſufficient; for after ſeveral attempts, there was always ſomething wanting to render the ſucceſs of the operation certain. The whole ſecret of blanching, therefore, was found to lie in the preparation of this ſuet; and this he at length diſcovered to conſiſt only in the firſt frying, and burning it. This ſimple operation not only gives it the colour, but puts it into a condition to give the iron a diſpoſition to be tinned, which it does ſurpriſingly.

The melted tin muſt alſo have a certain degree of heat, for if it is not hot enough, it will not ſtick to the iron; and if it is too hot, it will cover it with too thin a coat, and the plates will have ſeveral colours, as red, blue, and purple; and upon the whole will have a caſt of yellow. To prevent this, by knowing when the fire has a proper degree of heat, they might try with ſmall pieces of iron; but, in general, uſe teaches them to know the degree, and they put in the iron when the tin is at a different ſtandard of heat, according as they would give it a thicker or a thinner coat. Sometimes alſo they give the plates a double layer, as they would have them very thickly covered. This they do by dipping them into the tin, when very hot, the firſt time, and when leſs hot, the ſecond. The tin, which is to give the ſecond coat, muſt be freſh covered with ſuet, and that with the common ſuet, not the prepared. Philoſ. Tranſ. N° 406. p. 634.

LATUS, in *Ichthyology*, the name of a fiſh of the coracinus, or umbra kind, caught in the Nile, and in the Adriatic and Mediterranean ſeas. It much reſembles the common coracinus, but is larger, and has not the beard which hangs from the chin in that ſpecies; and its body is ſomewhat rounder. It is eſteemed a very delicate fiſh. Rondelet. de Piſc. p. 130.

LATUS, in *Anatomy*, a name given by many authors to one of the muſcles of the anus, now generally called the *levator ani*.

LATUS *muſculus*, in *Anatomy*, is alſo a name given by Riolanus, and others, to a muſcle called by Albinus *latiſſimus colli*, and by others *platyſma myoides*, and *quadratus genæ*. Part of this muſcle ariſing from the cheek, is called by Santorini the *muſculus riſorius novus*. See QUADRATUS.

LATUS *pulſus*, a *broad pulſe*, a term uſed to expreſs that ſort of *pulſe*, in which the artery is very ſenſibly dilated at every ſtroke.

LATUS *rectum*, in *Conics*, the ſame with PARAMETER.

LATUS *tranſverſum* of the hyperbola, is a right line, intercepted between the vertices of the two oppoſite ſections; or that part of the common axis, which is between the vertices of the upper and lower cone.

Such is the line ED (*Tab. Conics, fig.* 1.) where alſo D*d*, and E*e*, may be the parameters belonging to the two oppoſite ſections DLRO, and OEOR.

To this *latus tranſverſum* anſwers the longeſt diameter in the ellipſis; which Apollonius calls the *tranſverſe axis*, or *diameter*.

LATUS *rectum* is a right line belonging to a conic ſection, drawn through the vertex of the ſection of the cone, and within it; as the line EE, or DD, in the figure above referred to.

LAVA, is a name given by the Italians to the liquid and vitrified matter, diſcharged by Veſuvius, Ætna, and other volcanos, at the time of their ERUPTION.

This *lava* is a mixture of ſtones, ſand, earth, metallic ſubſtances, ſalts, &c. calcined, rendered fuſible, and vitrified by the fire of the volcanos: but as the maſs of which it originally conſiſts is very heterogeneous, the *lava*, when cold, appears under various forms and colours.

The pureſt *lava*, is a hard black, homogeneous, compact glaſs: of this kind is the ſtone found in many parts of Peru, and called by the Spaniards *piedra di Gallinazo*. There is another ſpecies of *lava*, which is hard, heavy, and compact, like marble, and which is ſuſceptible of a very fine poliſh. This is converted at Naples to a variety of domeſtic uſes. There is another kind which is a groſſer ſtone, and commonly aſh-coloured, uſed for building and paving the ſtreets. That which is found on the ſurface is ſtill more groſs and ſpongy, and reſembles the ſcoria of metals.

LAVACRUM, in *Botany*, a name given by ſome authors to the common wild teaſel, or *diſpacus ſylveſtris major*. Ger. Emac. Ind. 2.

LAVARETUS, in *Ichthyology*, a name of a ſmall fiſh called by ſome the *gang fiſh*, and the *shingus*, and by Morgrave the *curimato*. It ſeems of a middle nature, between the trout and herring-kind, and is caught in vaſt quantities in the months of March and April, in ſeveral of the lakes in Germany, and is pickled, and ſent to

different parts of the world. It seldom grows to more than four inches long.

LAVATERA, *tree-mallow*, in *Botany*, a genus of the *monadelphia polyandria* class: the characters are; that the flower has a double empalement, the outer of one leaf, short, obtuse and trifid, the inner of one leaf and quinquefid, and both permanent; the flower hath five petals joined at their base, and spread open above; it has many stamina, joined in a column below, and loose above: they are inserted in the petal, and terminated by kidney-shaped summits; the germen is orbicular, and supporting a short cylindrical style, crowned by many briftly stigmas; the empalement afterwards becomes a fruit with several capsules, covered in front by a hollow kind of shield, each capsule having one kidney-shaped seed. Miller reckons eleven and Linnæus nine species.

LAVATION, in *Antiquity*, a feast of the Romans, in honour of the mother of the gods, instituted in memory of the day when the worship of Cybele was transferred from Phrygia to Rome, and celebrated on the twenty-fifth of March.

LAVATORY, or LAVADERO, a name given to certain places in Chili and Peru, where gold is got out of earth by washing.

M. Frezier gives us the following description of the *lavatories* of Chili: they dig deep into the earth, in such places as they have reason to expect gold in; and, in order to facilitate this digging, they turn a stream of water upon the spot, loosening the earth as much as possible all the time, that the current may have the greater effect, and tear up the earth more strongly. When they are got to the earth they want, they turn off the stream, and dig dry.

The earth that they now get is carried on mules, and discharged into a baſon, made somewhat in the manner of a smith's bellows, into which a little rivulet of water runs with a great deal of rapidity, dissolving the parts of the earth, and carrying every thing away with it, excepting the particles of gold, which, by their great weight, precipitate to the bottom of the baſon, and mix with a fine black sand, where they are almost as much hidden as they were before in the earth. See *History of* GOLD.

Sometimes they find very considerable pieces in *lavatories*, particularly some pieces of twenty-four ounces each. There are several *lavatories* where they find these pepitas, or pieces of virgin gold, of a prodigious size. Among others, they tell of one that weighed five hundred and twelve ounces, bought by the count de la Moncloa, viceroy of Peru.

Nine or ten leagues to the east of Coquimbo are the *lavatories* of Andacoll; the gold whereof is twenty-three carats fine. Their work here always turns to great profit, excepting when the water fails them. The natives maintain, that the earth is creative (*creatrix*); that is, it produces gold continually; because, after having been washed sixty or eighty years, they find it impregnated afresh, and draw almost as much out of it as at first.

LAUDANUM, a name given by the chemists to certain preparations, chiefly extracts of opium, on account of their excellent qualities; the word being derived from *laudare, to praise*.

We have divers kinds of *laudanum*; as Sydenham's *liquid laudanum, tartarized liquid laudanum*, &c. See OPIUM.

LAUDICOENI, among the *Romans*, formed of *laus, praise*, and *cœna, supper* or *entertainment*, applauders, or persons who, for a reward, attended the rehearsal of plays and orations, in order to raise, or join in the acclamation. See ACCLAMATION and APPLAUSE.

LAUDS, LAUDES, the second part of the ordinary office of the breviary, said after matins; though, heretofore, it ended the office of the night.

The *laudes* consist principally of psalms, hymns, &c. whence they took their name, from *laus, laudis, praise*.

LAVENDER, *lavandula*, in *Botany*, a genus of the *didynamia gymnospermia* class. Its characters are these: the flower, which has an oval permanent empalement of one leaf, is of the lip kind, with one petal, having a cylindrical tube spreading above; the upper lip is bifid and open, the under lip cut into three equal segments; it has four short stamina, two of which are shorter than the other; it has a germen divided into four parts, which turn to four oval seeds sitting in the empalement.

We have three or four species of this plant in our gardens, all which are propagated by planting their cuttings or slips, in March, in a place where they may be shaded. They must be watered till they have taken good root, which will be in about two months; after which they may be planted out where they are to remain. They thrive best in an open situation, and gravelly soil. They grow taller in richer ground, but they are there very subject to be destroyed in hard winters, and their flowers are never so well scented.

The flowers and summits of the narrow-leaved *lavender* are, in a very eminent degree, cephalic and nervine. They are often employed as a perfume, and medicinally as mild stimulants and corroborants, in palſies, vertigoes, lethargies, and tremors of the limbs, both internally and externally.

The flowers are sometimes used in the form of a conserve, into which they are reduced by beating them, while fresh, with thrice their weight of double refined sugar. Water extracts by infusion nearly all the virtue both of the leaves and flowers: in distillation with water, the leaves yield a small portion of essential oil; but the flower in their most perfect state about one ounce from sixty. This oil is of a bright yellowish colour, a very pungent taste, and posſesses, if carefully distilled, the fragrance of the *lavender* in perfection: it is given internally from one drop to five, and employed in external applications for stimulating paralytic limbs, and for destroying cutaneous insects. Rectified spirit extracts the virtue of *lavender* more completely than water. The simple spirit of *lavender*, prepared by pouring a gallon of proof spirit on a pound and a half of the fresh-gathered flowers, and drawing off five pints by the heat of a water-bath, is richly impregnated with the fragrance of the flowers. More compounded spirits, in which other aromatics are joined to the *lavender*, have been distinguished by the name of English or pally drops: the college of London directs three pints of the simple spirit of *lavender*, and one pint of spirit of rosemary, to be digested on half an ounce of cinnamon, half an ounce of nutmegs, and three drams of red saunders, as a colouring ingredient: the college of Edinburgh orders a gallon and a half of rectified spirit of wine to be drawn over from three pounds of fresh *lavender* flowers, one pound of those of rosemary, and three ounces of lemon peel; and afterwards three ounces of cinnamon, one of cloves, one of cubebs, and two of red saunders, to be macerated for three days in the distilled spirit. These preparations are taken internally on sugar or in any convenient vehicle from ten to one hundred drops, and used externally in embrocations, &c. Lewis's Mat. Med.

The broad-leaved *lavender*, to which foreign writers have given the name of SPIKE, appropriated by some of our's to the first, is stronger both in smell and taste than the other and yields in distillation almost thrice as much essential oil; but the flavour of the oil and of the plant itself is much less grateful: the oil is like wise of a much darker colour, inclining to green. Lewis. See *Oil of* SPIKE.

LAVENDER *cotton, santolina*, in *Botany*, a genus of the *syngenesia polygamia æqualis* class. Its characters are these: it has a compound flower, with a scaly hemispherical empalement; the flower is uniform, composed of many funnel-shaped hermaphrodite florets, which are longer than the empalement, cut into five parts at the top; and which turn backward: they have five very short hair-like stamina, terminated by cylindrical summits; and an oblong four-cornered germen, supporting a slender style, crowned by two oblong depressed horn stigmas; the germen becomes a single oblong four-cornered seed, which is either naked, or crowned with very short down, and ripening in the common empalement. Miller enumerates twelve species, one of which is known by the name of *female* SOUTHERNWOOD.

LAVENDER, *French*. See CASSIDONY.

LAVENDER, *sea, limonium*, in *Botany*, is joined by Linnæus to the genus of STATICE. Its characters are these: the flowers have an imbricated perianthium, and are funnel-shaped, composed of five petals; it has five awl-shaped stamina, crowned by prostrate summits; and a small germen crowned by pointed stigmas; the empalement of the flower becomes a capsule that close at the neck, but expanded above where the seeds are lodged. There are twelve species. Miller.

The common *sea-lavender* is an astringent, and is given with good success against diarrhœas, dysenteries, proluvia of the menses, and hæmorrhages of all kinds. The roots and leaves are the parts most used.

LAVENDER, *bulbous-rooted sea, or* SIDE-*saddle flower, statice*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the flower has a double empalement, the under composed of three oval leaves which fall away, and the upper having five coloured leaves which are permanent; it has five oval inflexed petals, which include the stamina, whose tails are oblong, oval, and erect; and a great number of small stamina, terminated by target-shaped summits; in the centre is situated a roundish germen, supporting a short cylindrical style, crowned by a target-shaped, three-cornered stigma covering the stamina, and is permanent; the germen becomes a roundish capsule, with five cells, filled with small seeds. There are two species.

These plants are esteemed for the singular structure of their

their leaves and flowers; but there is some difficulty in getting them to thrive in England. They grow naturally on the bogs of North America and Carolina.

LAVER, in *Botany*. See TREMELLA.

LAVER *bread*, a sort of food made of a sea-plant, otherwise called the *oyster-green*, or *sea-liver-wort*. It is said to be used in the county of Glamorgan, and other parts of Wales.

LAVER, in *Scripture History*, a sacred utensil placed in the court of the Jewish tabernacle, consisting of a bason, whence they drew water by cocks, for washing the hands and feet of the officiating priests, and also the entrails and legs of the victims.

LAVERNA, in *Antiquity*, the goddess of thieves and cheats among the Romans, who honoured her with public worship, because she was supposed to favour those who wished that their designs might not be discovered. Varro says, that she had an altar near one of the gates of Rome; hence called *Porta Lavernalis*.

LAUGERIA, in *Botany*, a genus of the *pentandria monogynia* class: the corolla is divided into five segments; and the fruit is a drupe, including a five-celled nucleus.

LAUGHER, a name given to a particular species of pigeon, called by Moore the *columba rideus*. It is about the size of the common pigeon, and much of the same make; but it has a very bright pearl-coloured eye, almost white, and is a mottled red, or blue. They are said to be brought from Jerusalem, and the country thereabouts. When the cock of this species courts the hen, he has a guttural cooing, not unlike the gurgling of a bottle of water, when poured out hastily; and after this he always makes a noise, not unlike laughing, from the singularity of which he has obtained his name.

LAUGHTER, an action or passion peculiar to man. Authors attribute *laughter* to the fifth pair of nerves, which sending branches to the eye, ear, lips, tongue, palate, and muscles of the cheek, parts of the mouth, præcordia, &c. there hence arises a sympathy, or consent, between all these parts; so that when one of them is acted upon, the others are proportionably affected.

Hence a savoury thing seen or smelt, affects the glands and parts of the mouth, a thing seen or heard, that is shameful, affects the cheek with blushes; on the contrary, if it please and tickle the fancy, it affects the præcordia, and muscles of the mouth and face, with *laughter*; if it causes sadness and melancholy, it likewise affects the præcordia, and demonstrates itself by causing the glands of the eyes to emit tears.

Dr. Willis accounts for the pleasure of kissing from the same cause; the branches of this fifth pair being spread to the lips, the præcordia, and the genital parts; whence arises a sympathy between those parts.

LAVIGNON, the name of a French shell-fish, common on the coast of Poitou, of the chama-kind, having a very thin pair of shells for its covering, and which never can shut close, in the manner of the oyster or muscle, or other common bivalve shells. The fish therefore always buries itself in the mud by way of security. The shells are very smooth and polished, especially on the inside, and they are naturally white. This colour they always retain within, though their outer surface is often tinged black by the mud.

They are often buried five or six inches deep in the mud, but it is always easy to know where they are, because they must keep a free communication with the water above; by means of a round aperture, of about a tenth of an inch diameter, which opens from the surface of the mud to every shell fish. When the shells of this fish are opened to their utmost width, it is easy to see a sort of arm with which each is furnished, in the manner of the common muscle, for its progressive motion. This part serves them to bury themselves in the mud, and to raise themselves out of it again, when they are inclined to seek a new habitation; unto which it makes its way in a more speedy manner than would easily be thought.

When the creature is plunged to its proper depth under ground, it yet receives the benefit of the water above, by means of two pipes, or proboscides, which have each a double aperture at their ends. These take in water, and throw it out again, alternately, for the uses of the animal, and either of the two is indifferently qualified to answer either purpose. The fish has a power of lengthening, or shortening these pipes at pleasure, and, when it pleases, takes them wholly into the shell. Mem. Acad. Par. 1710.

LAVIN, in *Natural History*, a name given by the people of the Philippine Islands to a species of hawk, a bird of great beauty, being variegated all over with yellow, black, and white. They call it also SIGUR.

LAUNCE, in *Ichthyology*. See AMMODYTES.

LAUNCEGAYS, in our *Old Writers*, a kind of offensive weapons, now disused, and prohibited by the statute 7 Rich. II. cap. 13.

LAUNCH, in the sea phrase, is *to put out*: thus they say, *launch the ship*; that is, put her out of the dock, or out of the key, &c.

To facilitate the operation of *launching*, the ship, when she is first built, is supported by two strong platforms, laid with a gradual inclination to the water, on the opposite sides of her keel, to which they are parallel. Upon the surface of this declivity are placed two corresponding ranges of planks, which compose the base of a frame, called the CRADLE, whose upper part envelops the ship's bottom, to which it is securely attached. Thus, the lower surface of the cradle, conforming exactly to that of the frame below, lies flat upon it, lengthways, under the opposite sides of the ship's bottom; and as the former is intended to slide downwards upon the latter, carrying the ship along with it, the planes or faces of both are well daubed with soap and tallow. The necessary preparations for the *launch* being made, all the blocks and wedges, by which the ship was formerly supported, are driven out from under her keel, till the whole weight gradually subsides upon the platforms, which are accordingly called the ways. The shores and stanchions, by which she is retained upon the stocks till the time of *launching*, are at length cut away, and the screws applied to move her, if necessary. The motion usually begins at the instant when the shores are cut, and the ship slides downward along the ways, which are generally prolonged under the surface of the water to a sufficient depth, to float her as soon as she arrives at the farthest end thereof. When a ship is to be *launched*, the ensign, jack, and pendant, are always hoisted, the last being displayed from a staff erected in the middle of the ship. Ships of the first rate are commonly constructed in dry docks, and afterwards floated out, by throwing open the flood-gates, and suffering the tide to enter, as soon as they are finished. Falconer.

LAUNDER, in *Mineralogy*, a name given in Devonshire, and other places, to a long and shallow trough, which receives the powdered ore after it comes out of the box, or coffer, which is a sort of mortar, in which it is powdered with iron pestles.

The powdered ore, which is washed into the *launder* by the water from the coffer, is always finest nearest the grate, and coarser all the way down. See BUDDLE and *Dressing of* ORE.

LAURA, Λαύρα, primarily signifying *village*, *street*, or *hamlet*, a name given to the residences of the ancient MONKS. Authors cannot agree about the difference between a *laura* and a monastery: some pretend, that a *laura* was a monastery, wherein there lived at least a thousand monks; but this is in no-wise credible. The more natural opinion is, that the ancient monasteries were the same with the modern, consisting of large buildings, divided into halls, chapels, and cells, possessed by the monks, each of whom had his apartment; but the *lauræ* were a kind of villages, whereof each house was inhabited by one or two monks at the most; so that the houses of the Chartreux seem, in some measure, to represent the ancient *lauræ*, and those of the other monks proper monasteries. The term *laura* was only understood of the religious places in Egypt, and the East, where their houses stood apart from each other, and were not joined by any common cloister, the monks that inhabited them only meeting in public once a week.

LAURACES *lapis*, in *Natural History*, the name of a stone said to be of great virtues against the head-ach, but not known among us, nor described by the ancients.

LAUREAT, *poet*, is a well known office in the king's household. Sir John Hawkins observes, that there are no records which ascertain the origin of the institution of the office in this kingdom, though there are many that recognize it. It appears that as early as the reign of Henry III. there was a court poet, named Henry de Avranches, who is supposed to have had an appointment of a hundred shillings a year, by way of *salary* or *stipend*. In 1341 Petrarch was crowned with laurel in the Capitol by the senate of Rome; afterwards Frederic III. emperor of Germany, gave the laurel to Conradus Celtes; and ever since the counts palatine of the empire have claimed the privilege of solemnly investing poets with the bays. Chaucer, who was contemporary with Petrarch, and acquainted with him while abroad, assumed the title of *poet-laureat* on his return to England; and in the twelfth year of Richard II. obtained a grant of an annual allowance of wine. We read of persons under the same title in the reigns of Edward IV. Henry VII. and VIII. and of James I. who, in 1615, granted to his *laureat* an annual pension of one hundred marks. In the year 1630, this pension was augmented, by letters patent of Charles I. to 100*l. per annum*, with an additional grant of one terce of Canary Spanish wine, to be taken out of the king's store of wines yearly. Hawkins's Hist. of Music, vol. iv. p. 13.

LAUREATION, a term in the Scottiſh univerſities, uſed for the act of taking up the degree of a maſter of arts, to which the ſtudents are admitted after four years ſtudy in the univerſity.

LAUREL, *padus*, in *Botany*; Linnæus has joined this genus to the PLUM. Its characters are theſe: the empalement of the flower is bell-ſhaped, of one leaf, indented in five parts at the brim; and the flower has five large roundiſh petals which ſpread open, and are inſerted in the empalement; it has from twenty to thirty awl-ſhaped ſtamina, which are inſerted in the empalement; and a roundiſh germen ſupporting a ſlender ſtyle; the germen becomes a roundiſh fruit, incloſing an oval pointed nut, having rough furrows. Miller enumerates ſix ſpecies, one of which is called in America baſtard mahogany.

This tree is very eaſily propagated, by planting cuttings of it in September, in a cool ſhady border, where they will very ſoon take root, and the year afterwards are to be removed into beds, and placed at two or three feet diſtance; and when they have ſtood here two years, they will be fit for tranſplanting into the places where they are to ſtand. The beſt ſeaſon for making this laſt removal is April. This is the better method when they are deſigned for dwarfs; but if they are intended for high trees, they ſhould be raiſed from berries, as they then always grow much faſter. The berries ſhould be ſown as ſoon as they are ripe, covering them an inch thick with earth, and the young plants will appear the ſpring following, when they ſhould be cleared of weeds, and watered in dry weather. In the following autumn they ſhould be tranſplanted, and ſet at a foot diſtance; and when they are two years older, may be removed to the places where they are to remain.

Laurel berries are held to be carminative, emollient, and reſolvent. They are given internally in ſuppreſſions of urine and the menſes, in colics, in pains after delivery, and all nervous complaints. Externally they are uſed in emollient cataplaſms and fomentations.

The diſtilled water, and the infuſion of the leaves of the *laurel* are poiſonous; both the water and the infuſion having been obſerved to bring on convulſions, palſy, and death, when taken by the mouth, or anus.

This was diſcovered by the accident of two women dying ſuddenly at Dublin, after drinking ſome of the common diſtilled *laurel*-water. Several experiments were then made on dogs, and communicated to the Royal Society by Dr. Madden, and afterwards confirmed by Dr. Mortimer, which plainly ſhewed the poiſonous effect of *laurel*-water. See Phil. Tranſ. N° 418, 420.

The *laurel* being an ever-green, and abounding with a warm eſſential oil, it was at firſt imagined that other ever-greens might partake of the ſame poiſonous quality. But by Dr. Madden's experiments made on the leaves of the yew-tree, and on box-leaves, no ſuch quality appeared. Phil. Tranſ. N° 418.

The expreſſed juice of *laurel*-leaves has the like poiſonous effects with the diſtilled water and the decoction.

Several things were tried as antidotes to this poiſon, as bole, vinegar, and milk. The two former did little good, but the dog which drank the milk recovered, without any bad ſymptoms. However it is ſaid that infuſions of the leaves, made properly very weak, are commonly uſed in Holland in diſorders of the lungs.

LAUREL, *Alexandrian*. See BUTCHER'S *Broom*.

LAUREL, *dwarf*, of *America*. See KALMIA.

LAUREL, *ſea-ſide*, *phyllanthus*, in *Botany*, a genus of the *monoecia triandria* claſs. Its characters are theſe: it hath male and female flowers in the ſame plant; the empalements of the flowers in both ſexes are permanent, bell-ſhaped, and of one leaf, cut into ſix parts, which ſpread open; the flowers have no petals according to ſome, or no empalements according to others; the male flowers have three ſhort ſtamina, which join at their baſe, but ſpread aſunder at their top, and are terminated by twin ſummits; the female flowers have an angular nectarium ſurrounding the germen, which afterwards becomes a roundiſh capſule with three furrows, having three cells, each containing a ſingle roundiſh ſeed. Miller enumerates only one, and Linnæus ſix ſpecies. Miller.

LAUREL, *ſpurge*. See SPURGE *laurel*.

LAURELS, pieces of gold coined in the year 1619, with the king's head laureated, which gave them the name of *laurels*: the twenty-ſhilling pieces whereof were marked with XX. the ten-ſhillings X. and the five-ſhilling pieces with V.

LAURENCE, *canons of St.* an order of regular canons, ſo called from the monaſtery of St. Laurence d'Oulx, in Dauphiné.

This congregation is ſaid to have been founded by St. Benedict. It was deſtroyed by the Vandals, and continued uninhabited till the middle of the eleventh century. In 1057, Odo, count of Savoy, gave it to one Gerard, and his canons. This donation was confirmed in 1065, by Cunibert, biſhop of Turin, who added to it above forty other churches; by which means a very conſiderable congregation was formed, to whom the ſucceeding popes, and counts of Savoy, granted a great many privileges.

It had thirty priories; the chief, who is the prior of the congregation, bears the title of proveſt, and exerciſes a ſpiritual juriſdiction throughout his proveſtſhip.

LAURENTALIA, or LARENTALIA, called alſo *Larentinalia*, *Laurentales*, and *Larentales*, feaſts celebrated among the Romans on the tenth of the calends of January, or twenty-third of December, in memory of Acca Laurentia, wife of the ſhepherd Fauſtulus, and nurſe of Romulus and Remus.

Acca Laurentia, from whom the ſolemnity took its name, is repreſented as no leſs remarkable for the beauty of her perſon, than her laſciviouſneſs; on account of which, ſhe was nick-named by her neighbours, *lupa*, *ſhe-wolf*; which is ſaid to have given riſe to the tradition of Romulus and Remus being ſuckled by a wolf. She afterwards married a very rich man, who brought her great wealth; which, at her death, ſhe left to the Roman people; in conſideration whereof they performed her theſe honours; though others repreſent the feaſt as held in honour of Jupiter Latiaris. See LARENTINALIA and LARES.

LAURENTIA. See LOBELIA.

LAUREOLA. See SPURGE *laurel*.

LAURINUM. See DAPHNEIDON.

LAURO *ceraſo*, in *Botany*. See LAUREL.

LAUROTAXA, in *Botany*, a name uſed by Columna, and ſome other authors, for the narrow-leaved kind of *ruſcus*, or butcher's broom, called by others *biſſingua*.

LAURUS. See BAY-*tree*.

The gum BENZOIN, CAMPHOR, and SASSAFRAS, are obtained from different ſpecies of this genus.

LAURUSTINE, in *Botany*. See WAYFARING-*tree*.

LAW, a command or precept, conſtituting a rule of action, and coming from ſome ſuperior authority, which an inferior is obliged to obey; or, according to ſome, *law* is a command, or mandate of ſome perſon, or power, whoſe precept carries with it the reaſon of obedience.

The word is formed from the Saxon *lah*, *lage*, which ſignifies the ſame.

Thus, the commands of God with reſpect to men, of a city with reſpect to the citizens, and univerſally of all powerful beings in reſpect to thoſe who cannot reſiſt, are called their *laws*.

The nature of a *law* will be moſt clearly diſcovered by ſhewing wherein it differs from *covenant*, *counſel*, and *right* or *equity*; with all which it is frequently confounded.

Law is confounded with covenant, by thoſe who take *laws* to be nothing elſe but *ſynallagmata*, or forms of living determined by the conſent of mankind: among which is Ariſtotle, who defines a *law*, "a declaration deter-"mined by the common conſent of a city, ſhewing in "what manner things are to be done:" which is not ſo much the definition of a *law*, as of a *civil law*; nor yet properly of a civil *law*; for this common conſent is no more than a mutual covenant, which does not oblige any perſon, and conſequently is not any *law*, till ſome ſupreme power be conſtituted with a power to compel, and to make it penal to tranſgreſs it. Here then the covenant is confounded with the *law*, which leads into abſurdities; for a covenant is a promiſe; a *law*, a command.

The difference between a counſel and a *law*, is this.

A counſel is a precept, wherein the reaſon of obedience is taken from the thing itſelf preſcribed; a command is a precept, wherein the reaſon of obedience depends on the will of the preſcriber; for we cannot properly ſay, *ſic vole*, *ſic jubeo*, unleſs *ſtet pro ratione voluntas*. A *law* comes from a perſon who has a power over thoſe whom he commands; a counſel, from him who has no ſuch power. To do what is enjoined by a *law*, is an act of duty; what by a counſel, an act of choice, or freewill.

Law is confounded with right or equity, by thoſe who perſiſt in doing what is permitted by the *divine law*, though prohibited by the *laws* of the country. What is prohibited by the *divine law*, cannot be permitted by the *civil law*; nor what is commanded by the *divine law*, be prohibited by the *civil law*; but what is permitted by the *divine law*, may, notwithſtanding, be prohibited by the *civil law*: for the inferior *laws* have a power of reſtraining the liberty left the ſuperior *laws*, though they cannot enlarge it. Now right or equity is a natural liberty, not conſtituted by *laws*, but free of them; for take away *laws*, and liberty is complete.

This liberty is firſt reſtrained by the *natural* and the *divine law*, the reſt reſtrained by the *civil laws*; and what

remains

remains unreſtrained by the *civil laws*, may be again reſtrained by the conſtitution of particular cities and ſocieties. There is a great difference, therefore, between *law* and right, *lex & jus*; for *law* is a chain; but right, a liberty; and they differ as two contraries.

Law may be divided, with reſpect to its different origins, into *divine* and *human*.

LAW, *divine*, may be conſidered as twofold, with reſpect to the two different manners in which God notifies his will to man; viz. *natural* (or *moral*), and *poſitive*.

LAW, *natural*, is that which he has made known to all mankind, by an innate light, called *natural reaſon*.

LAW, *poſitive*, is that which he has revealed by his prophets or by perſons ſupernaturally commiſſioned and inſpired, and found only in the holy ſcriptures: as thoſe *laws* delivered to the Jews, relating to the divine worſhip and polity, which may be called *divine civil laws*, as being peculiarly directed to that people.—Again,

Natural law may be divided into that *natural law* of men, which in a peculiar ſenſe, is called *the* LAW *of nature*; and the *natural law* of countries, commonly called *the* LAW *of nations*.—The precepts are the ſame in both theſe: but becauſe, when ſocieties are once inſtituted, certain perſonal properties become veſted in men; that *law*, which, when we ſpeak of the duties of men ſeverally, we call *the natural law*; when tranſferred to cities or countries, we call *the law of nations*.

M. Regis ſays, that the *laws* of nature are the dictates of right reaſon, which teach every man how he is to uſe his natural rights; and the *laws* of nations, the dictates, in like manner, of right reaſon, which teach every ſtate how to act and behave themſelves toward others.

LAWS, *human*, are all civil. See CIVIL.

For, according to Hobbes, the ſtate of man, out of ſociety, is a ſtate of war; wherein, no one being ſubject to another, there can be no other *law* beſides the dictates of natural reaſon, which is the *divine law*.

LAWS, *civil*, may be divided, with regard to the difference of their ſubject-matter, into *ſacred* and *ſecular*.

LAWS, *ſacred*, are thoſe that relate to religion; that is, to the ceremonies and worſhip of the Deity, and which are not preſcribed by any poſitive divine *law*.

LAWS, *ſecular*, are thoſe that relate to property, &c. commonly called by the name *civil*.—Farther,

Civil laws, conſidered with regard to the two offices of the legiſlator; *viz.* to judge and to compel; may be divided into two branches; the one *diſtributive*, the other *vindictive*, and *penal*.

LAW, *diſtributive*, is that by which every man has his right; or, it is that which conſtitutes the rules and meaſures of things, whereby we know what belongs to us, and what to others; ſo as we may not diſturb or interrupt others in the enjoyment of their own, nor be interrupted by them; and what each man may lawfully do, or not do.

LAW, *vindictive*, is that branch by which the puniſhments to be inflicted on thoſe who violate the *laws*, are determined.

The diſtributive and vindictive are not two ſpecies of *laws*, but two parts of the ſame *law*. For if a *law* ſay no more than "Whatever you catch in your net, in the "ſea, ſhall be your's," it is in vain; for though another take from you what you have caught, it is ſtill your's; in regard, in the ſtate of nature, where all things are common, your's and another's are the ſame thing. So that what the *law* defines to be your's, was your's before that *law*, and will be your's after it, though poſſeſſed by another.—A *law*, therefore, is but an empty ſound, unleſs it determine the thing to be your's in ſuch a ſenſe, as to forbid every body elſe from diſturbing you in the poſſeſſion of it. But ſuch prohibition will be vain, unleſs there be a penalty annexed to it.—A *law*, therefore, muſt contain both theſe parts, that which prohibits, and that which puniſhes. The firſt whereof, which is called *diſtributive*, is prohibitory, and ſpeaks to all; the latter, called *vindictive*, or *penal*, is mandatory, and ſpeaks only to the public officers. Whence it follows, that to all *civil laws* there is annexed a penalty, either implicitly, or explicitly; and where that puniſhment is not aſcertained, either by writing, or by example, it is ſuppoſed to be arbitrary, and to depend on the pleaſure of the legiſlator: for that is no *law*, which may be violated impuné.

Civil or *municipal law* is well defined by judge Blackſtone to be "a rule of civil conduct, preſcribed by the "ſupreme power in a ſtate, commanding what is right, "and prohibiting what is wrong." And he obſerves, that every *law* may be ſaid to conſiſt of ſeveral parts: one, DECLARATORY, whereby the rights to be obſerved, and the wrongs to be eſchewed, are clearly defined and laid down: another *directory*, whereby the ſubject is inſtructed and enjoined to obſerve thoſe rights, and to abſtain from the commiſſion of thoſe wrongs; a third, *remedial*, whereby a method is pointed out to recover a man's private rights, or redreſs his private wrongs: to which may be added a fourth, uſually termed the *ſanction*, or *vindicatory* branch of the *law*, whereby it is ſignified what evil or penalty ſhall be incurred by ſuch as commit any public wrongs, and tranſgreſs or neglect their duty. Blackſt. Comm. book i. p. 54.

Civil laws, conſidered with regard to the different manners of promulgating them, are of two kinds; *ſcriptæ* and *non ſcriptæ*; or *written* and *unwritten*.

LAWS, *written*, are thoſe which require either the voice, or ſome other ſign of the legiſlator's will, to become *laws*.

LAWS, *unwritten*, are ſuch as need no other promulgation beſides the voice of nature, or natural reaſon; of which kind are all natural *laws*.

Hence it appears, that though the natural *laws* be deſcribed in the writings of the philoſophers, they are not therefore to be called *written laws*: nor are the writings of lawyers, *laws*, for want of the ſupreme authority; nor the *reſponſa prudentum*, or opinions of judges, *laws*, excepting ſo far as they are allowed by the ſupreme power, to paſs into uſe; and then they are called *leges ſcriptæ*, written *laws*; not becauſe of their uſe, but becauſe of the will of the ſupreme power, which is argued from their paſſing into uſe.

The firſt principle or *law* of nature, according to Hobbes, is ſelf-preſervation.—Thomaſius will have it to be our own happineſs, which falls in at laſt with the ſentiment of Hobbes.—Puffendorf maintains it to be ſociality.—Valentine Alberti, the belief that we are the image of God.—Henry and Samuel Cocceius, the will of God.—Grotius, right reaſon.—Velthemius, the intrinſic decency, or turpitude, of actions.—Strimeſius and Janus, that we are to love God, ourſelves, and our neighbour.

LAW is alſo applied to the ſeveral policies of ſtates and people, or the maxims and rules they have agreed upon, or received from their magiſtrates, whereby to live in peace and mutual ſociety.

The *laws* of the twelve tables, were the ancient *laws* of the Romans, for which the Decemviri were ſent into Greece, and which ſerved them for the ground-work of all their juriſprudence.

The celebrated *laws* of the more modern days, are thoſe of the Angli, the Werini, or Thuringi; of the Boii, or Bavarians; thoſe of the Burgundi, Germans, Danes, and Norwegians; of the Franks, the Friſons, the Lombards, the Gothic *laws*, the Martins, or Mercian *laws*; the *laws* of the Saxons, Scots, Sicilians, Viſigoths; the *laws* of Oleron, the Molmutin *laws*, and the Salic *laws*.

LAW, *lex*, among the firſt Romans properly ſignified an ordinance of the people, made at the requeſt of a magiſtrate, particularly a conſul.

Theſe ordinances differed from the plebiſcita, and ſenatus-conſulta, and even from other ordinances made at the requeſt of any other magiſtrate beſide a conſul, though thoſe too bore the name of *laws*.

Thus, though Aquilius and Falcidius were only tribunes when they made their requeſt, yet we ſtill ſay, the *Aquilian law*, the *Falcidian law*, &c.

The ſeveral *laws* of the Romans are diſtinguiſhed, 1. By the name of him at whoſe requeſt they were paſſed; as the *Cornelian law*, the JULIAN *law*, &c. 2. By the matter or ſubject of the *law*; and hence came the terms, *teſtamentary laws*, as the FURIAN, VOCONIAN, &c. *judiciary laws*, AGRARIAN *laws*, &c.

3. Sometimes by the crimes againſt which they were made. For inſtance: the *laws* touching *poiſoning*, *parricides*, &c. the *laws* of *concuſſion*, *peculate*, &c.

The CODEX and AUTHENTICÆ are the *laws* and conſtitutions of the Roman emperors; and the DIGEST is a compilation, made by the emperor Juſtinian's order, of the ſeveral opinions and judgments of the moſt learned in the Roman *law*; to which he gave the ſanction of *laws*, as appears by the epiſtle preſixed to the work; and it is this that properly conſtitutes the Roman *law*.

The *lex talionis*, or *law of like for like*, is the moſt ancient and equitable *law* in the world. It was obſerved by the Hebrews.

LAW *of England* may be divided into two kinds; the *lex non ſcripta*, the unwritten or common *law*; and the *lex ſcripta*, the written or ſtatute *law*. The former, i. e. the unwritten or common *law*, is properly diſtinguiſhable into three kinds. 1. General cuſtoms, which are the univerſal rule of the whole kingdom, and form the COMMON *law* in its ſtricter and more uſual ſignification. 2. Particular cuſtoms, which for the moſt part affect only the inhabitants of particular diſtricts. See CUSTOM and COMMON *law*. 3 Certain particular laws, which by cuſtom are adopted and uſed by ſome particular courts of pretty general and extenſive juriſdiction. See CANON *law*, and CIVIL *law*.

The *leges ſcriptæ*, or written *laws* of the kingdom, are Statutes

ſtatutes, acts, or edicts, made by the king's majeſty, by and with the advice and conſent of the lords ſpiritual and temporal and commons in parliament aſſembled. The oldeſt of theſe now extant, and printed in our ſtatute-books, is the famous MAGNA *charta*, as confirmed in parliament, 9 Hen. III. See STATUTE.

There is another diviſion of our laws, more large and particular; as into the prerogative or crown *law*; the *law* and cuſtom of parliament; the common *law*; the ſtatute *law*; reaſonable cuſtoms; the *law* of arms, war, and chivalry; eccleſiaſtical or canon *law*; civil *law*, in certain courts and caſes; foreſt *law*; the *law* of marque and reprizal, the *law* of merchants; the *law* and privilege of the ſtannaries, &c. But this large diviſion may be reduced to the common diviſion; and all is founded on the *law* of nature or reaſon, and the revealed *law* of God, as all other *laws* ought to be. 1 Co. Inſt. 11.

LAW has alſo a more ſpecial ſignification, wherein it is taken for that which is lawful with us, and not elſewhere: as, "Tenant by the courteſy of England."

Thus we alſo ſay, to *wage law (vadiare legem)*, and to *make* or *do law (facere legem)*. See WAGER, and MAKE.

LAW, *aſſigned by*. See ASSIGNED.

LAW, *covenant of*. See COVENANT.

LAW, *foreſt*. See FOREST.

LAW, *frank*. See FRANK.

LAW, *intendment of*. See INTENDMENT.

LAW, *martial*. See MARTIAL.

LAW, *Poyning's*. See POYNING.

LAW, *releaſe in*. See RELEASE.

LAW, *ſalic*. See SALIC.

LAW, *ſuit in*. See SUIT.

LAW, *ſumptuary*. See SUMPTUARY.

LAW, *ſurrender in*. See SURRENDER.

LAWS, *by*. See BY-LAWS.

LAWS, *cock-pit*. See COCKPIT.

LAWS *of the ſtage*. See STAGE.

LAW *of arms*, is that *law* which gives precepts how rightly to proclaim war, to make and obſerve leagues, to attack the enemy, and to puniſh offenders in the camp.

Common things concerning arms and war are under the cognizance of the conſtable and marſhal of England. 13 R. II.

LAW *of marque*, a *law* by which thoſe who are driven to make uſe of it, take the goods, or ſhipping, of the party that has done them wrong, and of whom they cannot get ordinary juſtice, wherever they can take him within their own bounds or precincts. 27 Ed. III. cap. 17.

LAWS *of Molmutius*. See MOLMUTIN *laws*.

LAWS *of Oleron*. See OLERON.

LAW *of the ſtaple*, the ſame with LAW *merchant*.

LAW *merchant*, a ſummary ſort of *law*, originally differing from the *common law*, though now adopted, and become a part of the *laws* of the kingdom. One point of it conſiſts in this, that if there be two joint merchants of wares, and one of them dies, his executor ſhall have the moiety; which is not allowed in the caſe of others, not merchants. See CUSTOM.

LAW, *ſpiritual*, is the eccleſiaſtical or canon *law*, allowed and authorized in this realm, ſo far as it is not againſt the common *law*, nor againſt the ſtatutes and cuſtoms of the kingdom. And according to ſuch eccleſiaſtical *laws*, the ordinary and other eccleſiaſtical judges proceed in caſes within their cognizance.

LAW is alſo uſed figuratively in ſpeaking of the rules or order wherein any thing is performed.

Thus we ſay, the *laws* of motion, the *laws* of mechanics, the *laws* of fluids, the *laws* of chance, of a game, &c. *Laws* of friction, of reſiſtance, of deſcent of bodies, &c. *Laws* of elaſticity, rarefaction, reflexion, refraction, &c. all which ſee under their proper heads.

LAW, in *Scripture Hiſtory*, one of the three diviſions of the Old Teſtament, comprehending Geneſis, Exodus, Leviticus, Numbers, Deuteronomy. See CANON.

LAW-*day*, *lagedayum*, in our old *Law Writers*, was any day of open court, and commonly uſed for the courts of a county or hundred. It is alſo called *view of frank-pledge*, or *court-leet*. *Et quieti ſint de ſectis comitatuum & hundredorum wapentorum, de viſu franci plegii & lawdayorum*, &c.

LAWFUL. See UNLAWFUL.

LAWFUL *moan*. See NAAM.

LAWING *of dogs*, a phraſe uſed in our ancient law-writers. Thus, maſtiffs muſt be *lawed* every three years, Crompton Juriſd. fol. 163, that is, three claws of the fore-foot ſhall be cut off by the ſkin, or the ball of the fore-foot cut out. See EXPEDITATION.

LAWLESS *court*, a court held on King's-hill, at Rochford in Eſſex, every Wedneſday morning next after Michaelmas day, at cock-crowing; at which court they whiſper, and have no candle, nor any pen and ink, but a coal. He that owes ſuit or ſervice there, forfeits double his rent, every hour he is miſſing.

This court is called *lawleſs*, becauſe held at an unlawful hour; or, perhaps, *quia dicta curia lege*, becauſe opened without any form. It is mentioned by Camden; who ſays, this ſervile attendance was impoſed on the tenants, for conſpiring at the like unſeaſonable time to raiſe a commotion.

LAWLESS *man*, *ex lex*. See OUTLAW.

LAWN, a ſpacious plain in a park or adjoining to a noble ſeat. Theſe ſpacious plains make a noble figure before grand houſes, and the great rule in regard to their dimenſions, is to make thoſe in large parks as large as the ground will admit, never leſs, if poſſible, than thirty or forty acres: but in gardens a *lawn* of eight or ten acres is ſufficient. *Lawns* ought always to lie open to the front of the houſe, and to be open to the neighbouring country, not pent up with trees; and the moſt happy ſituation is, when the beſt rooms of the houſe front the eaſt, or rather the ſouth-eaſt, and the *lawn* lies immediately before them; becauſe the ſun, in an afternoon, in this caſe, ſhines on the proſpect, and at the ſame time not into the rooms. The beſt ſituation for a *lawn*, except this, is on the ſouth ſide of a houſe; for if on the weſt, it expoſes the houſe to too much wind, and if on the north too much open to the cold. It is beſt therefore to plant trees and wilderneſſes on the weſt and north ſides of houſes.

As to the figure of a *lawn*, ſome recommend an exact ſquare, others an oblong ſquare, ſome an oval, and others a circular figure: but neither of theſe ſhould be invariably regarded; becauſe it ought to be contrived ſo as to ſuit the figure of the ground: and as there ſhould be trees planted for ſhade on the boundaries of the *lawn*, the ſides may be broken by irregular plantations of trees, ſome breaking forwarder than others, and not too cloſely crouded together, which make a better appearance than any regular plantations can do. When there are no good proſpects beyond the *lawn*, it will be proper to have it bounded on every ſide by plantations, which may be brought round pretty near to each end of the houſe, ſo that perſons may ſoon get into ſhade. For this purpoſe thoſe trees ſhould be preferred, which grow large, ſtrait and handſome. Of the deciduous trees, the moſt proper are the elm, oak, beech, and cheſnut; and if there are ſome clumps of ever-green trees intermixed with the others, they will add to the beauty of the whole, eſpecially in the winter ſeaſon: the beſt ſorts for this purpoſe are lord Weymouth's pine, and the ſilver and ſpruce firs. Miller.

LAWNS, in *Commerce*. See CAMBRIC.

LAWSONIA, in *Botany*, a genus of the *octandria monogynia* claſs. Its characters are theſe: the flower, which has a ſmall permanent empalement divided into four parts at the top, is compoſed of four oval ſpear-ſhaped petals which ſpread open, and eight ſlender ſtamina ſtanding by pairs between them; it has a roundiſh germen, which becomes a globular capſule, ending in a point, having four cells filled with angular ſeeds. There are two ſpecies, natives of both the Indies.

The leaves of this ſhrub are much uſed by the Egyptian women to colour their nails yellow, which they eſteem an ornament.

LAWYER, *(legiſta, legiſperitus, juriſconſultus)* by the Saxons called *lahmon*; is a counſellor, or one learned in the law: and *lawyers*, ſuch as counſellors, attornies, &c. are within the act 3 Jac. I. againſt extortion; but it has been held only to extend to officers. See COUNSELLOR, ATTORNEY, &c.

LAXATIVE, in *Medicine*, is uſed to ſignify a looſe ſtate or diſpoſition of the body; ſo as to go frequently to ſtool.

LAXATIVES, or LAXATIVE *medicines*, are ſuch as promote this diſpoſition; which they do by ſome ſmooth, ſoftening quality, taking away the tenſity of the fibres, and facilitating the paſſage of the contents of the inteſtinal tube through it; for which reaſon all oily ſubſtances come under this claſs. See CATHARTICS, EMOLLIENTS, &c.

LAXIOR *toga*. See TOGA.

LAY, the name of a kind of ancient poeſy, or poem, among the French, conſiſting of very ſhort verſes.

There were two ſorts of *lays*; the *great*, and the *little*.

LAY, *greater*, was a poem conſiſting of twelve couplets of verſes, of different meaſures.

LAY, *little*, was a poem conſiſting of ſixteen or twenty verſes, divided into four couplets.

Theſe *lays* were the lyric poetry of the old French poets, who were imitated by ſome among the Engliſh. They were principally uſed on melancholy ſubjects, and are ſaid to have been formed on the model of the trochaic verſes of the Greek and Latin tragedies.

Father Mourgues gives us an extraordinary inſtance of one of theſe ancient *lays*, in his Treatiſe of French Poetry:

Sur l'appuis du monde
Que faut il qu'on fonde
D'espoir ?
Cette mer profonde,
En debris feconde
Fait voir
Calme au matin, l'onde
Et l'orage y grande
Le soir.

LAY *the land*, in *Sea Language*. See LAND.

LAY-*land*, in *Husbandry*, denotes fallow ground, which lies untilled. See FALLOW, and PLOUGHING.

LAY-*brother*, among the *Romanists*, a pious, but illiterate perſon, who devotes himſelf, in ſome convent, to the ſervice of the religious.

The *lay-brother* wears a habit different from that of the religious, nor ever enters into the choir, or the chapter. He is not in any orders, nor does he make any vow, excepting of conſtancy and obedience.

Theſe *lay-brothers* make the three vows of religion.

In the nunneries are alſo *lay-ſiſters*, who never enter the choir, &c. and who are only retained for the ſervice of the convent.

The inſtitution of *lay-brothers* began in the eleventh century. The perſons on whom this title was conferred, were ſuch as were too ignorant to become clerks, and who therefore applied themſelves wholly to bodily labour. It ſeems to have taken its riſe from hence, that the laity in thoſe days had not, for the generality, the leaſt tincture of learning; whence alſo thoſe came to be called *clerks*, by way of diſtinction, who had ſtudied a little, and were able to read.

In ſome orders they are only retained by a civil contract, which, however, binds them for life; in other orders they are to paſs through four years of probation, as among the Jacobins; or ſeven, as among the Feuillants. The Capuchins admit none before nineteen years of age. The Jeſuits call them *coadjutors*.

LAY-*canons*. See CANON.

LAY-*communities*. See COMMUNITY.

LAY-*corporation*. See CORPORATION.

LAY-*fee*, *feudum laicum*, land held in fee from a *lay*-lord, by the common ſervices to which military tenure was ſubject, as diſtinguiſhed from the *eccleſiaſtical* holding in *frankalmoign*, diſcharged from thoſe burdens.

LAY-*patronage*. See PATRONAGE.

LAYS, *ſides*. See SIDE-*lays*.

LAY, *vaunt*. See VAUNT-*lay*.

LAYER, in *Huſbandry* and *Gardening*, a young tender ſhoot or twig of a plant, not far from the ground, which is bent down, and ſeveral joints or knots buried under ground, till, having ſtruck root below, it is cut and ſeparated from the parent ſtock, and commences a new plant.

Many trees may be propagated by *layers*, which do not produce ſeeds here. The young branches of the former year's ſhoots of trees, ſhould be choſen to make *layers*, becauſe theſe are generally more inclined to put out roots than the older wood. When theſe are produced near the ground, they may with greater facility be layed. Theſe ſhoots ſhould be diveſted of their ſide-branches, if they have any; and thoſe ſorts of trees which put out roots with difficulty, ſhould have a ſlit made upward at a joint, in that part which is to lie in the ground; or a piece of wire twiſted cloſe round the branch at the ſame place, which will check the mounting ſap, and cauſe them to put out roots; the ground ſhould be well dug, and the clods broken; then the ſhoots ſhould be layed five or ſix inches under the ſurface, driving down a peg to each to prevent their riſing, leaving the end of the ſhoots twelve or eighteen inches above ground in an erect poſition.

The ſeaſon for laying hardy trees that ſhed their leaves, is in October, but for ſuch as are tender, in March; but for ever-greens, July or Auguſt are good ſeaſons.

If you would *lay* young trees from a high ſtandard, the boughs of which cannot be bent down to the ground, then you muſt make uſe of ozier-baſkets, boxes, or pots, filled with fine-ſifted mould mixed with a little rotten willow-duſt, which will keep moiſture to aſſiſt the *layer* in taking root: this muſt be ſet upon a poſt or treſſel, and the bough be laid as before; covering the ſurface with moſs to prevent the earth from drying.

There are many kinds of trees and plants which will not put out roots from their woody branches, though laid down with the utmoſt care; yet if the young ſhoots of the ſame year are laid in July, they will often put out roots very freely: ſo that when any plants are found difficult to propagate by *layers* in the common way, they ſhould be tried at this ſeaſon; but as theſe ſhoots will be ſoft and herbaceous, they muſt not have too much wet, for that will cauſe them to rot. Miller.

LAYES, or LEYES, a term uſed in many parts of England for ſuch paſture ground as had been formerly tilled and ſown.

LAYMAN, a perſon not engaged in any order of eccleſiaſtics: accordingly, in the diſtribution of the people, *laity* is oppoſed to the CLERGY, and may be divided into three diſtinct ſtates, viz. the CIVIL, the MILITARY, and the MARITIME.

LAYMAN, among *Painters*, a little ſtatue, or model, either of wax or wood, whoſe joints are ſo made, that it may be put into any attitude, or poſture. Its chief uſe is for the caſting and adjuſting draperies, for the clothing of figures.

Some call it, after the French, *manequin*, q. d. *a little man*.

LAYR. See LAIR.

LAZARETTO, or LAZAR-HOUSE, a public building, in manner of a hoſpital, for the reception of poor ſick.

LAZARETTO, in ſome countries, is an edifice appointed for perſons coming from places ſuſpected of the plague, to perform QUARANTINE.

This is uſually a large building, at a diſtance from any city, whoſe apartments ſtand detached from each other, &c. where ſhips are unladen, and their crew is laid up for forty days, more or leſs, according to the time and place of their departure.

LAZARI *morbus*, a name given by ſome writers to the ELEPHANTIASIS.

LAZAROLE, in *Botany*. See MEDLAR.

LAZARUS, *St.* or LAZARO, a military order, inſtituted at Jeruſalem by the Chriſtians of the Weſt, when they became maſters of the Holy Land; whoſe buſineſs was, to receive pilgrims under their care, guard them on the roads, and defend them from the inſults of the Mahometans.

Some ſay, this order was inſtituted in 1119. Pope Alexander IV. confirmed it by a bull in 1255, giving it the rule of St. Auguſtine.

The knights of this order, being driven out of the Holy Land, part of them retired into France, and were eſtabliſhed there under Louis VII. who beſtowed on them the country of Boigny, near Orleans. Innocent VIII. ſuppreſſed the order of *St. Lazaro* in Italy in 1490, or, rather, he united it to that of Malta. Leo X. re-eſtabliſhed it in Italy in the beginning of the ſixteenth century. In 1572, Gregory XIII. united it in Savoy to that of St. Maurice, juſt inſtituted by duke Emanuel Philibert.

In France, this order was united to that of Notre Dame, of Mount Carmel in 1608, and had ſome new advantages conferred on it by Louis XIV. The knights of *St. Lazarus* are allowed to marry, and yet have penſions upon benefices.

LAZARUS, *Fathers of St.* called alſo LAZARITES, a name given to certain regular clerks of a congregation inſtituted in France, in the ſeventeenth century, by M Vincent.

They take the denomination from a houſe in the Fauxbourg St. Denis of Paris: they have a ſeminary in Paris, called the ſeminary *des bons enfans*. The vows they make are ſimple, and may be diſpenſed with on occaſion.

LAZIVRAD, in *Natural Hiſtory*, one of the oldeſt names by which we find the *lapis lazuli* expreſſed in authors.

LAZZI, a denomination given by the Saxons to that rank of people, who were born to labour, and being of a more ſervile ſtate than our ſervants, becauſe they could not depart from their ſervice without leave of the lord, but were fixed to the land where born and in the nature of ſlaves: hence the word *lazzi* or *lazy*, ſignifies thoſe of a ſervile condition. See EDHILING.

LAZULI. *Lapis* LAZULI, a ſort of precious ſtone, of a blue colour, veined and ſpotted with white and yellow.

This is the ſame with what is otherwiſe called *azure* ſtone, by the ancients *cyaneus*, and *cæruleum*; by Meſue, the *ſtarry* ſtone; and by Pliny, and many of the ancients, *ſapphirus*.

Waltherius conſiders this ſtone as a ſpecies of jaſper; and Cronſtadt, more juſtly, as a ſpecies of that order of earths which have been lately called ZEOLITES. It is found in ſeveral parts of Europe, in mines of gold, ſilver, and copper; as alſo in quarries of marble; which laſt is that generally in uſe. But the moſt coſtly comes from Perſia and the Eaſt Indies.

Naturaliſts diſtinguiſh three kinds of *lapis lazuli*: the firſt called of the *old rock*, which is pure, ſmooth, a fine blue, with beautiful yellow ſtreaks like veins of gold, which yet are frequently no more than veins of pyrites. The ſecond, called that of the *new rock*, is debaſed by a mixture of common ſtones; its colour is weaker, and its price lower: theſe two kinds are brought from Perſia and Siam. The third kind is brought from the mountains of Auvergne: this is mixed with the common rock whence it is dug; it is of a pale blue, and is ſprinkled with

with greeniſh ſpots, with veins of pyrites. This, when ſufficiently charged with ſpots of green, is often ſold for the Armenian ſtone, which may be readily diſtinguiſhed by its being leſs hard than the *lazuli*, ſoon loſing its blue colour in moderate fire, and raiſing an effervescence with acids; its baſis ſeeming to be a calcareous earth.

M. Margraaf, and alſo M. Cronſtedt, have made experiment on this ſtone, carefully cleanſed from all white, pyritous, or heterogeneous matters. From theſe experiments we learn, 1. That this ſtone is ſoluble in acids, without effervescence; and when it has been previouſly calcined, it forms gelatinous maſſes with acids. 2. That by calcination it is not deprived of its blue colour, till at leaſt that operation has been long continued. 3. By a violent fire it is fuſible, and forms a frothy glaſs, ſometimes whitiſh, and ſometimes of a duſky yellow colour, but always clouded with blue ſpots. 4. Fuſed with nitre, and thrown red-hot into water, it tinged the water with a blue colour, which diſappeared in ſome hours. By this operation the ſtone loſt its blue colour. 5. Some of this ſtone, powdered and mixed with glaſs frit, produced a tranſparent citron-coloured glaſs. With borax, it produced a glaſs of a chryſolite colour. 6. It gave no ſigns of its containing copper, notwithſtanding it has been conſidered as an ore of copper by moſt authors. 7. It ſhewed marks of iron, by forming a blue precipitate, like Pruſſian blue, when a phlogiſticated alkali was added to a ſolution of this ſtone in acids. 8. Margraaf ſays, that by adding vitriolic acid to ſolutions of this ſtone in nitrous and marine acids, a white precipitate was formed, which he ſuppoſes was calcareous earth. Nevertheleſs, Mr Cronſtedt affirms, that this ſtone does not effervesce with acids. Perhaps the calcareous earth was not eſſential, but only accidental. 9. Cronſtedt ſays, that a precipitate is formed by adding a fixed alkali to a ſolution of this ſtone in vitriolic acid, which, being ſcorified with borax, yields a regulus of ſilver. He ſays, that by ſcorification with lead, two ounces of ſilver have been obtained from a hundred pounds of the ſtone. Mr. Margraaf does not mention that he found any ſilver; or that he ſearched for any. Perhaps it is only accidental. Dict. Chem. art. *Lapis Lazuli*, note *(q)*.

The goldſmiths, lapidaries, and thoſe who make inlaid works with precious ſtone, uſe the *lapis lazuli* in ſeveral pieces of workmanſhip; but its moſt common uſe is in making that fine blue, ſo much valued by limners, which is called ultra-marine, and which is ſold ſo dear.

This blue is prepared according to Wallerius, in the following manner. The ſtone, firſt finely levigated and mixed with linſeed oil, is to be added to a paſte, made by mixing together equal parts of yellow wax, colophony, and pitch, i. e. half a pound of each, with half an ounce of linſeed oil, two ounces of turpentine, and two ounces of maſtic. To three or four parts of this paſte one part of the levigated ſtone, mixed with linſeed oil, is to be added, and after this mixture has been digeſted together during three or four weeks, it is to be thrown into hot water, and ſtirred till the blue colour ſeparates and diffuſes in the water, which is then to be poured off. The blue matter is left to ſettle, and, when dry, is the ultramarine required. See *Ultramarine* BLUE.

The *azure-ſtone*, or *lapis lazuli*, in order to be of a good quality, and proper to make the ultramarine, ought to be heavy, but little mixed with common rock, and to have veins of copper, of a deep blue, inclining to that of indigo. Care muſt be taken that it has not been rubbed with olive oil, which makes it look of a deeper blue than it would be naturally. This impoſition may be diſcovered by breaking the ſtone; if its colour be paler within than without, it is a proof that it was falſified. You may alſo know whether the azure ſtone be of good quality, by heating in the fire, till it be red hot, which ought not to change its colour; it ought, on the contrary, to receive a new degree of brightneſs from that trial.

Azure in powder, which is alſo called aſhes of azure, is nothing but the azure in ſtone, or ſmalt, pulverized, which comes from ſeveral places, and particularly from Germany and Holland. The latter is dearer, and more valued; becauſe in the uſe, its colour comes nearer to that of the ultramarine; whence it is called common, or Dutch ultramarine. The powder azure of Germany ought to be ſandy, well grained, and of as deep a colour as poſſible. As for the Dutch azure, the finer and paler it is, the more it is valued: for though its colour ſeems to be loſt, as it were, by being ground very fine, yet when uſed by the limner it recovers a very bright blue. At Amſterdam they diſtinguiſh its different qualities and degrees of goodneſs by certain letters; the beſt is marked with F F C; the ſecond with F C, and the third M C. There are alſo ſome inferior ſorts, which are valued according as they come nearer this laſt.

The *lapis lazuli* is of ſome uſe in medicine: they prepare it by calcining and waſhing it ſeveral times; which done, it makes an ingredient in the famous confection of alkermes. It has been thus given in doſes of half a dram and a dram, and ſaid to operate ſtrongly by ſtool and vomit. Some have recommended it in epileptics and intermitting fevers: Dolæus tells us, that in this laſt diſorder, the above doſes, taken on the approach of a fit, with two or three ſpoonfuls of brandy, were with him a ſingular ſecret.

It has been alſo recommended againſt apoplexies, and melancholy, as well as epileptic and quartan agues; but its violent operation as a purgative and emetic, has frighted people out of the uſe of it; and the preſent practice takes no notice of it in any of the above intentions. The chemical writers give us proceſſes for maſteries, tinctures, and elixirs of *lapis lazuli*, but they are wholly out of uſe.

There is alſo factitious or artificial azure, made with indigo, or the juice of violets, mixed and ground with a ſort of chalk. The common ſort is made with ſal armoniac and ſilver plates; or with ſulphur, quickſilver, and ſal armoniac.

The method of making the Venetian counterfeit *lapis lazuli* is this: melt in a pot, in a glaſs-houſe furnace, equal quantities of the faireſt LATTIMO, and the whiteſt cryſtalline glaſs; when this is in fuſion, mix into it, by ſmall parcels at a time, the blue ſmalt uſed by the painters; make frequent proofs of the colour, and when it is right let the whole ſtand twelve hours, and then work it. If the metal riſe in the pot, put in a piece of leaf gold to keep it down. This makes a fine plain blue ſubſtance, repreſenting the plain blue parts of the natural *lapis lazuli*. Neri's Art of Glaſs, p. 117.

A counterfeit *lapis lazuli* may be alſo made by fuſing ten pounds of either of the compoſitions for hard glaſs, (ſee *Colouring of* GLASS) with an ounce and a half of zaffer, and half an ounce of magneſia, till a very deep tranſparent blue glaſs be produced. When the maſs is cold, powder it, and mix it with three-quarters of a pound of calcined bones, horn, or ivory, by grinding them together: then fuſe this mixture with a moderate heat, till the ingredients are thoroughly incorporated, and form the melted maſs into cakes, by pouring it on a clean bright plate of copper or iron. In order to give it veins of gold, mix GOLD-*powder* with an equal weight of calcined borax, and temper them with oil of ſpike: let the cakes be painted with this mixture with freſh veins as are deſired, and put into a furnace of a moderate heat; and the gold will be cemented to the glaſs as firmly as if the veins had been natural.

LE *roy le veut.* } See LE ROY.
LE *roy s'adviſera.* }

LEA *of yarn*, is uſed in ſome parts of England for a certain quantity of *yarn*. At Kiddermiſter it ought to contain two hundred threads, on a reel four yards about. Stat. 22 & 23 Car. II.

LEACH-*brine*, a word uſed by the Engliſh ſalt-workers to expreſs the BRINE which runs out from the ſalt, when it ſtands in the baſket to drain, immediately after being taken out of the pan; and alſo the liquor left in the pan, when no more ſalt will ſhoot. This is alſo called the *mother-brine*, and BITTERN. In the German ſalt-works they always throw this liquor away. In our *brine*-ſalt works in Cheſhire they always preſerve it, and add it to the next boiling; and in the Newcaſtle, and other ſea-water ſalt-works, they ſave it for the making the bitter purging ſalt, called *Epſom-ſalt*.

LEAD, called by the chemiſts *Saturn*, a coarſe, heavy, impure metal, of a pale or livid white colour, the ſofteſt, and moſt flexible, the leaſt ductile and tenacious, leaſt elaſtic, and leaſt ſonorous of all the metals. Next to gold, platina, and mercury, it is the heavieſt metal, being upwards of eleven times heavier than an equal bulk of water. See *Specific* GRAVITY.

Lead is ſo ſoft and flexible, that it is eaſily cut with a knife, ſhaved with a plane, grooved for windows, by being drawn through the glazier's vice, and flatted, by paſſing betwixt wooden rollers, into large thin ſheets. When broke by repeated bendings, each piece appears drawn out ſmooth to an edge, like the fracture of well nealed gold and ſilver. It is not, however, ductile to any great degree, either in the form of wire or of leaf, being much inferior in this reſpect to all the other malleable metals; though its ſurface, when cut by a ſharp inſtrument, appears ſmooth, compact, and ſhining, it quickly tarniſhes in the air, and becomes covered by a ſlight greyiſh ruſt. Nevertheleſs it reſiſts much longer than iron or copper the combined action of air and water, before it is decompoſed and deſtroyed. *Lead* is very fuſible, and melts, long before it becomes red-hot, a little later than tin or biſmuth, but ſooner than any other metal;

tal; the degree of heat neceſſary for this purpoſe being about the 540th degree of Fahrenheit's thermometer. It loſes of its malleability in proportion as it is heated; and as ſoon as it melts, it calcines, and greyiſh aſhes are formed upon its ſurface. The calcination and fuſion of *lead*, in particular circumſtances, produce MASSICOT, MINIUM, LITHARGE, and GLASS *of lead*. In a ſtate of incipient fuſion, or when it is returning from a fluid to a conſiſtent ſtate, it may be eaſily divided into ſmall grains or powder, by GRANULATION, or formed into SHOT.

Lead is well known to be in its natural ſtate a metal ſo little ſonorous, that it is even a proverbial expreſſion uſed to any metal that is leſs ſonorous than others, that it is almoſt as mute as *lead*.

Mr. Lemery, however, once ſhewed Mr. de Reaumur, and afterwards to the Academy of Sciences at Paris, a lump of *lead*, which had been left in one of his veſſels, after ſome chemical operation, which, when ſtruck, gave a very loud and acute ſound.

Mr. Lemery had no occaſion afterwards to repeat the experiment, which had afforded him this remarkable *lead*, and left it to Mr. Reaumur to diſcover the manner of doing it, who luckily hit upon it, without the difficulty he had expected from the reſearch; and, it appears, that we have a thouſand times met with ſonorous *lead*, without knowing it to be ſo.

The common way of melting *lead*, in order to the caſting it into moulds, is in iron ladles. It very rarely happens, that all that is melted in the ladle is caſt into the mould; but a ſmall quantity remains, which ſoon forms itſelf into a maſs in the ladle, and this maſs is always ſonorous. Its figure is uſually either that of the ſegment of a ſphere or of a ſpheroid, and it is plane or flat on one ſide, and convex on the other. The maſſes of this kind, examined by Mr. Reaumur, were all very ſonorous: there are, doubtleſs, certain proportions of their thickneſs to their diameter, which may make them more or leſs ſonorous, but all are conſiderably ſo: poſſibly, alſo, figures of a different kind may prove ſonorous; but Mr. Reaumur tried one convex on each ſide, and found it to have no ſound at all. Larger and thicker diſks of *lead* are ſometimes found ſonorous, but never ſo much ſo, as the figures firſt deſcribed. There are alſo two circumſtances, in which the maſs from the ladle itſelf is not ſonorous; the one is, when it is covered with a coarſe ſpungy cruſt, and the other, when its edges are extremely thin for any conſiderable ſpace. It is not the form, however, which does this alone, ſince pieces of the ſame figure, made by hammering and cutting, have no more ſound than *lead* in any other ſhape.

Theſe ſpeculations are not without their uſe. It is not to be ſuppoſed, indeed, that any form, into which *lead* can be caſt, can make it capable of anſwering the purpoſe of the more ſonorous metals in bells, &c. but it is very probable, that the caſting metals, naturally ſonorous, into a ſhape or figure, which alone can render a metal, naturally mute, highly ſounding, would make their ſounds much more perfect, more loud and clear. Experiment alone can determine this, and diſtinguiſh what is only probable, and what is true. It ſhould ſeem that the preſent form of bells, had their origin from the obſerving that pots, and other veſſels, made for more immediately neceſſary uſes, gave a great ſound; and thence, when bells were to be made, they caſt them, as nearly as conveniently might be, of that figure. Had they had equal opportunities of obſerving the ſonorous quality of metals caſt into the ſhape of ſegments of ſpheres, it is very probable that all the bells in the world had now been of that form. The figure of bells, uſed at preſent, is indeed very convenient for the ſuſpending them in churches; poſſibly a proper metal, caſt into the form above mentioned, would be more fit than in any other for houſe-clocks, where a great ſound is required.

Thoſe who have made an analyſis of *lead*, find it to contain a little mercury, ſome ſulphur, and a great deal of bituminous earth.

It has been proved, by the experiments of different chemiſts, that *lead* contains a real running mercury. Kunkel and Becher both ſeparated mercury from it; and Mr. Groſſe, of the Paris academy, has juſtified their experiments by producing the ſame effect; by means not only very different from theirs, but abſolutely oppoſite and contrary. They ſuppoſe that the mercury contained in *lead* is fixed there, either by acids or by ſulphurs, and therefore they uſed alkaline materials to diſengage and ſupport it. On the contrary, Mr. Groſſe uſed only acids, and by means of theſe procured a pure running mercury from this metal. His method was to diſſolve thin plates of *lead* in ſpirit of nitre, weakened with an equal quantity of water. He then obſerved a grey-coloured powder precipitate, which when tried on gold or copper, ſhewed itſelf to be mercurial, and even in the powder he ſaw ſmall globules of quickſilver. Mem. de l'Acad. des Scienc. 1733.

As there could be no poſſibility of the acids forming mercury with *lead*, it is very plain that it muſt have been originally there. But this proceſs probably does not ſucceed with every kind of *lead*; or that aqua fortis made uſe of in this experiment has been impregnated with quickſilver, in which caſe the mercury would precipitate in proportion as the *lead* diſſolved: for Macquer and Beaume ſay, that they have, with all poſſible attention, repeated this experiment of Mr. Groſſe without having obtained mercury.

In the trying *lead* by the teſt of the burning glaſs, a piece of that metal laid on a charcoal very readily melts, and afterwards wholly diſſipates itſelf in fumes; if it be placed on a piece of ſtone it fumes very much, and becomes at length a thin fluid reſembling oil, or melted reſin; and this liquor, in cooling, fixes itſelf into a ſort of glaſs, which has this peculiar quality, that it is always compoſed of plates, or ſcales, in the manner of talc; it is of a greeniſh or yellowiſh colour, with ſome reddiſh ſpots, and is very ſoft to the touch. If it be kept longer in the focus of the glaſs it ſpreads abroad upon the ſtone, and by degrees penetrates its ſubſtance, and promotes its fuſion. If the common calx of *lead*, red-*lead*, or litharge, be uſed inſtead of plain *lead* in this experiment, the event is the ſame: the whole becomes a thin fluid matter, which in cooling affords a flaky glaſs, like talc. Mem. Acad. Paris, 1709.

If this talcky glaſs of *lead* be expoſed to the ſame focus, laid on a piece of charcoal, it preſently melts, and reaſſumes the form of *lead*; and, if then taken away, and ſuffered to cool, is no way different from common *lead*. If the calx of *lead*, or red-*lead*, or litharge, be in the ſame manner melted in the focus of the burning-glaſs on a piece of charcoal, they in the ſame manner immediately re-aſſume the form of *lead*.

It appears from the whole, that there is in *lead* an oily inflammable matter, which is eaſily driven off either by the ſolar or by a common fire; that the baſis of *lead*, which appears alone, when this is driven off, is a ſcaly or talcky earth; and that this oily matter of *lead* is no way different from the oils of vegetables, ſince the oil of charcoal is able perfectly well to ſupply its place, and to reſtore this talcky earth to the form of *lead* again. See PHLOGISTON.

Lead is found in various countries, but it abounds particularly in England. It is found, too, in ſeveral kinds of foſſils and ſtones, ſome whereof, beſides, contain gold, ſome ſilver, others tin, &c.

It is melted in a furnace provided for that purpoſe, with a ſtrong coal-fire upon it; as it melts, it runs through a canal on one ſide, leaving the earth, ſtone, and ſcoria, with the aſhes of the coals.

It is purified by ſkimming it before it be cold, and throwing ſoet and other fat bodies into it. See REFINING *of lead*.

The common ores of *lead* are nearly of the ſame colour of *lead* itſelf, and appear compoſed of cubes or parallelepipeds, ſometimes large and regular, ſometimes irregular and ſmall. The ores of ſilver, copper, and other metals, except tin and iron, have often a *lead* ore intermixed: the common *lead* ores conſiſt of *lead* in the ſtate of a calx, blended with ſulphur: minium, litharge, or other calxes of *lead*, melted with ſulphur, form a compound ſimilar to them both in appearance and quality. There are alſo white or greyiſh, and yellowiſh-green ores; but they are rarely met with. They are very ponderous and rich in metal. On barely expoſing them to the flame of a candle, the *lead* quickly and plentifully melts out: they are ſometimes cryſtalline and ſemi-tranſparent; ſometimes opake, and little different in appearance from common ſtones.

Mr. Boyle obſerves that there is great difference, diſcernible by the eye, between different *lead-ores*. Some is ſo like ſteel that the workmen call it *ſteel-ore*: and this being of more difficult fuſion than ordinary, they mix it with other ore, by them called *firm-ore*, when they commit it to the furnace. He ſays, he likewiſe took notice of an ore, which, for its aptneſs to vitrify, and ſerve potters to glaze their veſſels, the miners call *pattern-ore*, and ſell it dearer than other ore. *Lead-ore* often yields ſilver, but not always. Mr. Boyle mentions ſome *lead ore*, he tried, ſo rich, as to yield ſeventy *per cent.* of *lead*; yet did not, though tried by one of the moſt expert artiſts, give one grain of ſilver. Boyle's Works Abr. vol. i. p. 150.

It is pretended by ſome, that the famous *lead*-mineral found near Freyung, in the Upper Palatinate, is *native lead*: but this is an error; we have an account of it in the Philoſophical Tranſactions, which does not give any ground

ground for this opinion. All that is there ſaid of it, is that it was at that time much eſteemed among the aſſayers of metals, as containing no mixture of any other metal with the *lead*: this might well recommend it to them, as ſaving much conſuſion, or much trouble in ſeparating its heterogene contents; but it is ſaid expreſsly there, that it is an ore, not a *native* metal: there being two kinds of it, one a cryſtalline ſtone, almoſt all pure *lead*; the other not ſo rich, but of a more rough and coarſe texture. Neither of theſe could be *native lead*; and it is remarkable, that they had leſs appearance of being ſo than many of our common ores. Phil. Tranſ. N° 3.

However, Dr. Morris relates that native *lead* is found intermixed with the *lead*-ore of a mine in Monmouthſhire. Phil. Tranſ. vol. lxiii. and Linnæus ſays, that he has ſeen what externally appeared to be ſuch.

This metal, as in common uſe, always contains ſome ſilver, which is not in quantity enough to be worth the charges of ſeparating. The moſt common proportion is not more than two drams to a centner. This, though of little conſequence on any other occaſion, is carefully inquired into by the aſſayers of the ores of metals, particularly in regard to the ores of ſilver, for the ſeparation of which from its ore *lead* is employed; and it occaſions a very great error, when its computation is neglected, in eſtimating the value of an ore from the aſſays. This increaſing ſilver is therefore always ſubtracted by the more accurate aſſayers; and in order to do this with the leſs trouble, a large quantity of *lead* is granulated at once for this uſe, and mixed by ſifting; then the uſual quantity employed in the aſſaying an ore is to be tried alone in a copel, and the bead of ſilver it affords carefully preſerved. After this, when the bead produced from a ſilver ore is weighed; that bead of ſilver, given by the *lead*, is to be put in the oppoſite ſcale among the weights, and then the weights balancing the bead, will, without more trouble, give the weight of the ſilver from the given quantity of its ore. Cramer's Art of Aſſaying, p. 216.

When the *lead*-ore is dug out, they beat it ſmall, then waſh it clean in a running ſtream, and ſift it in iron rudders. Their hearth or furnace is made of the clay or fire-ſtone: this they ſet in the ground, and on it build their fire, which they light with charcoal, continuing it with young oaken gads, blown with bellows, worked by men's treading on them. After the fire is lighted, and the fire-place hot, they throw their *lead* ore on the wood, which melts down into the furnace, and then with an iron ladle they take it out, and upon ſand caſt it into what form they pleaſe.

The mine-men ſometimes find the vein run up into the roots of trees, and yet do not obſerve any difference between thoſe and other trees. When the mine is near the ſurface, the graſs is ſometimes found yellow. They make no account of the virgula divinatoria; yet ſay, that when a mine is open, they may gueſs by it how far the vein will lead. The ore runs ſometimes in a vein, ſometimes diſperſed in banks; it lies many times between rocks; ſome of it is harder, others milder; ſometimes they have branched ore in the ſpar; about the ore is ſpar and cauk; and another ſubſtance, which they call *crottes*.

The method of ſeparating *lead* from its common fuſible ore by aſſaying, is this: beat the ore into a coarſe powder, like grains of coarſe ſand; weigh two decimaſtical centners of this powder, and put it into a teſt. Put upon this a tile, or elſe another teſt: the ore muſt be ſpread wide all over the bottom of the teſt: roaſt it in a fire moderate at firſt, but afterwards increaſed, ſo far as to make the teſt red-hot; leave it thus for a few minutes, then take off the tile, and in a ſhort time the ore will change its blackiſh to a yelloviſh colour. This ſhews that great part of the ſulphur is now diſſipated.

Beat this roaſted ore into a fine powder, and add twice as much of the black flux, and of filings of iron not ruſty, and of ſandiver, of each half a centner; powder all theſe in a mortar to mix them well; then put them into a crucible large enough to contain twice or three times as much; cover them over a quarter of an inch thick with common ſalt, and preſs all down with a finger; put a tile on a ſmall crucible, and ſtop the joint with a lute that will bear the fire; then dry the veſſel with a moderate heat; then put the crucible into a wind-furnace, and heap coals upon it, covering it ſome inches high; when the crucible is red-hot, you will hear the ſalt crackle, and this will be ſucceeded by a gentle hiſſing noiſe; ſo long as this laſts, keep the ſame degree of fire, but when it is over, increaſe the fire till the whole maſs is melted, which will be done in a quarter of an hour, in a moderate melting fire; then take out the crucible, put it upon the hearth of the furnace, which muſt be very dry, ſtrike it a few times with a hammer, to get all the *lead* together in the bottom; when it is cold take it out, and you will find by the weight of the regulus how much *lead* the ore contains. Cramer's Art of Aſſaying, p. 287.

This metal may be procured from its ore, of whatever kind that be, by a ſtratification with charcoal.

Lead ores may be aſſayed by the following proceſs of Mr. Gellert: mix a quintal of roaſted *lead ore* with a quintal of calcined borax, half a quintal of glaſs finely pulverized, a quarter of a quintal of pitch, and as much of clean iron filings; put this mixture into a crucible wetted with charcoal duſt and water; place the crucible before the nozzle of the bellows of a forge, and when it is red, raiſe the fire for fifteen or twenty minutes; then withdraw the crucible, and break it when cold. Some very fuſible ores, as the galena of Derbyſhire, may be aſſayed, as large quantities of it are ſmelted without previous roaſting, and without addition, merely by fuſion, during a certain time. For this purpoſe nothing more is requiſite than to keep the ore melted in a crucible with a moderate heat, till all the ſulphur is deſtroyed, and the metal be collected. To prevent the deſtruction of any part of the metal after it is ſeparated from the ſulphur, ſome charcoal duſt may be thrown over the ore, when put into the crucible; but if the galena be mixed with pyrites, eſpecially arſenical pyrites, it requires much roaſting and ſaline fluxes.

The ores of *lead* are known to be ſoftened, in a moderate red heat, into the conſiſtence of a paſte, but do not flow thin in a ſtrong fire: if iron filings are mixed, the iron abſorbs the ſulphur, and at the ſame time revives the *lead* into its metallic form. This is one of the moſt compendious methods of ſmelting *lead ores*, where the operation is performed in veſſels; and is the method uſed with the *lead ores* at Dal in Sweden, which, containing from twenty to twenty-ſix ounces of ſilver on the hundred pounds, are thus ſmelted in crucibles, without any loſs of the ſilver; and Mr. Scheffer obſerves, that the produce of *lead* is greater than that obtained by any other means. The ordinary yield of *lead* is from about one-third to upwards of two-thirds of the weight of the ore, according as it is leſs or more free from ſpar, or other heterogeneous earthy matters.

Lead is found of a lighter or deeper colour, according as it is more or leſs purified; though ſome make a difference in the colour of the ore, always eſteeming that moſt which is the whiteſt.

Some very able naturaliſts obſerve, that the weight of *lead* increaſes on long keeping, either in the open air, or underground. Mr. Boyle obſerves this particularly of the *lead* of churches, which, he ſays, frequently grows both in bulk and weight, ſo as to become too ponderous for the timber that before ſuſtained it; which ſome account for from the impurity, heterogeneity, and looſe texture of its parts, by means whereof the particles of the air, getting admiſſion within its pores, are attracted, and eaſily aſſimilated to it. But others, who rely wholly on experience, abſolutely deny the fact, as alſo that it is reproduced in mines before exhauſted, by letting them lie long to the open air; which others aſſert.

Lead is ſoluble with all acids. When combined to ſaturation with nitrous acid, it forms, as ſilver does, a cryſtallizable nitrous ſalt, with metallic baſe, called nitre of *lead*, which is capable of decrepitating and detonating, without the addition of inflammable matter, in conſequence of the phlogiſton retained by the *lead*. Pure vitriolic acid, and that contained in neutral vitriolic ſalts, when mixed with a ſolution of *lead* in nitrous acid, unites with the *lead*, ſeparating it from the acid, and forming with it a metallic ſalt, or vitriol of *lead*, which cryſtallizes and appears in form of a white precipitate, when the liquors do not contain a ſufficient quantity of water to diſſolve it. This ſalt is the ſame as that made by directly diſſolving *lead* in vitriolic acid. Marine acid, and all the neutral ſalts containing it, precipitate *lead* from its ſolution in nitrous acid, and unite with it, forming a metallic ſalt, called PLUMBUM *corneum*, or *Saturnus cornuus*, from its reſemblance to the LUNA *cornea*. Vegetable acids alſo diſſolve *lead*, and particularly its calces, with eaſe; but only the combinations of this metal with vinegar are known, becauſe theſe are uſed in medicine and the arts. Of theſe there are the CERUSS or *white* LEAD, the VINEGAR *of lead*, and *ſalt or ſugar of* LEAD. Cauſtic alkaline lixivia, boiled on plates of *lead*, diſſolve a ſmall portion, and corrode a conſiderable quantity: the ſolution ſtains hair black. Expreſſed oils diſſolve calces of *lead* by boiling, in ſuch large quantity as to become thick or conſiſtent. The *drying* OIL uſed by painters is linſeed oil, thus thickened with *lead*; and in this way are formed plaiſters, cements for water-works, paint for preſerving nets, &c. Theſe maſſes of *lead* combined with oil may be decompoſed by acids, which unite with the *lead*, and ſeparate the oil from them; and this oil proves ſoluble, like eſſential oils, in ſpirit of wine; a phenome-

non firſt taken notice of by Mr. Geoffroy. *Lead* is eaſily united to ſulphur, and burnt and calcined by expoſing it at once to the action of ſulphur, fire, and air.

All the metals may be conſidered, in certain circumſtances, as acting in the manner of menſtruums on one another, and of theſe none has ſo much power as *lead*. When *lead* is expoſed to a moderate fire in an earthen veſſel, the ſurface of the melted maſs is ſoon covered with ſcoriæ, in form of a thin ſkin of many colours: when the fire is ſo far increaſed as to make the veſſels quite red-hot, this ſkin melts a little, and is thrown to the ſides of the veſſel in form of a ſurfuraceous matter, of various yelloviſh or whitiſh colours, called *litharge*. After this the melted *lead* ſmoaks, and ſmall drops, reſembling the firſt ſcoriæ, riſe, and ſwim like globules of oil upon the ſurface; theſe are one after another added to the litharge at the ſides; and if the fire be kept in this degree, the whole ſubſtance of the *lead* is totally turned into litharge.

If copper be added to *lead* thus ſmoaking, it cauſes a much briſker ebullition than before, and the copper burſts, and divides, and ſeems to become one homogene maſs with the *lead*; this maſs is brittle, and if made with equal parts of *lead* and copper, reſembles tempered ſteel when broken. On expoſing the miſture to a fire no greater than that in which *lead* melts, the *lead* almoſt entirely runs off by itſelf; and the little *lead* that is retained in the pores of the copper, may be ſcorified and melted out by a fire conſiderably leſs than is ſufficient to make copper flow. Gold and ſilver melted thus with *lead* become brittle alſo, and gold becomes pale by the ſmalleſt admixture of it. They are diſſolved by melted *lead* in a ſlight red heat.

Tin and *lead* melt together with a fire ſtrong enough to melt the *lead* alone, and form a compound more fuſible than *lead* by itſelf, and is therefore employed as a SOLDER for *lead*; but when this is increaſed, ſo as to make the veſſels red, the tin immediately riſes up above the *lead*, in form of little whitiſh duſty hillocks, ſo that the whole looks as if aſhes had fallen into the veſſel; and the tin thus calcined, when cold, is variegated in colour, with white, yellow, and red. *Lead*, ſo long as it keeps its metallic form, can never be made to join with iron, though urged by ever ſo violent a fire: on continuing the fire, the *lead* ſcorifying or calcining, abſorbs the phlogiſton of the iron, and conſequently promotes the calcination of that metal; and when both are reduced into calces, the fuſible ſaturnine calx diſſolves the chalybeate into an opake brown or bluiſh glaſs: hence *lead* may be employed to purify the perfect metals from iron, as from other imperfect metals.

The ſemi-metals are all eaſily melted with *lead* by fire, and added in too large a quantity they take away its malleability.

Lead and all its products turn into glaſs by a ſtrong fire; and this glaſs, or in the place of it litharge melted with ſtones, and other vitrifiable ſubſtances, makes them run into glaſs with a much leſs fire than they otherwiſe would do; and if a very large quantity of this glaſs or litharge be added, they become ſo far attenuated as to run through the ſides of the veſſels. Lime-ſtones ſuffer the ſame change by means of this matter; and the incombuſtible ſtones, with proper management, are ſubject to the ſame fate; but unleſs theſe proceſſes are carefully conducted, the litharge or glaſs of *lead* gets away alone through the veſſel. Among the metals litharge facilitates the fuſion of copper and iron by the fire, but it conſumes a conſiderable quantity of them, and runs itſelf, with what it poſſeſſes, into glaſs; and, finally, the whole tin and its calx are with difficulty vitrified by glaſs of *lead*, and they loſe nothing by it: but if gold and ſilver are very frequently melted with litharge, they will at length be found to have loſt a little of their weight; but this ſmall quantity is not deſtroyed, but may, by the proper operations, be again regained out of the litharge. For the affinities of *lead*, ſee AFFINITY.

Lead is a metal of much uſe: it eaſily melts, and mixes with gold, ſilver, and copper; but not being able to endure the violence of the fire which they undergo, it riſes to the ſurface, and carries with it all that was heterogeneous in them; ſo that neither gold nor ſilver are refined without *lead*. Hence *lead* is called by the chemiſts *balneum ſolis & lunæ, lavacrum regis & reginæ, ſapo metallorum*, &c. See REFINING.

To which may be added, that the coarſer kind of precious ſtones, heated in *lead*, are ſaid to be thereby rendered much more brilliant.

Borrichius aſſerts, that *lead* reverberated in minium, converted into glaſs, reduced into ceruſs, or burnt into litharge, immediately reſumes its original figure, upon the dexterous application of a liſivial ſalt.

All theſe calces and glaſſes of *lead* are more eaſily revived than thoſe of any other metal. They can ſcarcely be melted but ſome part of the *lead* is revived, although no inflammable principle has been added, which proves that they retain much phlogiſton. If a piece of common flint-glaſs be ſurrounded in a crucible with ſoot, powdered charcoal, or other ſuch inflammable matters, and cemented for ſome time with a fire ſufficient to melt it, the *lead* will be revived through the whole internal ſubſtance of the glaſs, into little drops; and if the matter is brought into fuſion, the *lead* ſubſides, collected into one butter at the bottom. From this glaſs Dr. Lewis has extracted one fourth of its weight of perfect malleable *lead*. The calces and glaſs of *lead* abſorb the inflammable principle even from ſome other metallic bodies: if glaſs of *lead* be melted in an iron veſſel, or ſtirred in fuſion with an iron rod, great part of the *lead* will reſume its metallic form, a proportionable quantity of the iron ſcorifying. It is ſaid, that *lead*, recovered from its calces, proves ſomewhat harder and lighter than at firſt, and leſs ſubject to tarniſh in the air. But Dr. Lewis obſerves, that the difference, if any, is certainly very ſmall. Neumann's Chem. by Lewis, p. 55.

Lead is much uſed in building, particularly for covering, gutters, pipes, and in glaſs-windows. For which uſes, it is either caſt into ſheets in a mould, or milled; which laſt, ſome have pretended, is the leaſt ſerviceable, not only on account of its thinneſs, but alſo becauſe it is ſo exceedingly ſtretched in milling, and rendered ſo porous and ſpongy, that, when it comes to lie in the hot ſun, it is apt to ſhrink and crack, and conſequently will not keep out the water. Others have preferred the milled *lead*, or flatted metal, to the caſt, becauſe it is more equal, ſmooth, and ſolid.

The *lead* uſed by glaziers is firſt caſt into ſlender rods, twelve or fourteen inches long, called *canes*; and theſe, being afterwards drawn through their vice, come to have a groove on either ſide for the panes of glaſs; and this they call *turned lead*.

The method of paling or ſoldering *lead* for fitting on of imboſſed figures, &c. is by placing the part whereon the figure is to be paled, horizontal, and ſtrewing on it ſome pulverized reſin; under this they place a chafing-diſh of coals till ſuch time as the reſin becomes reddiſh, and riſes in pimples; they apply the figure, and rub ſome ſoft ſolder into the jointing: when this is done, the figure will be paled on, and as firm as if it had been caſt on.

Lead is much uſed in varniſhes and painting with oil, both as a colour and as a dryer. It is alſo uſed in the preparation of ENAMELS and of PORCELAIN as a flux, and makes the baſis of the GLAZING of almoſt all pottery wares; and by means of *lead* the moſt perfect metals are refined and aſſayed. See REFINING and ASSAYING.

LEAD, in *Medicine*. This metal is celebrated by ſome chemical writers for its great medical virtues; but after all, it ſeems to be a metal which ought to be given internally with the greateſt caution, and to be rather calculated for outward application. Its ore is ſo poiſonous, that the ſteam, ariſing from the furnaces where it is worked, infects the graſs of all the neighbouring places, and kills the animals which feed on it. Its beſt preparation is *ſaccharum ſaturni*; which, though capable of doing great good in hæmorrhages, and ſome other caſes, is apt, however, to bring on colics of ſo violent a kind, that the remedy often proves worſe than the diſeaſe.

The poiſonous quality of this *ore* is ſuch, that the people who live in the countries where it is dug, and near the places where it is waſhed, can keep neither dog nor cat, nor any kind of fowl, but all die in a ſhort time; and it has been known that a little houſe, in which *lead ore* had been kept for ſome time, though afterwards made very clean, and bedded with fern, infected calves which were put into it, ſo that all died in a very ſhort time; and it is a too common melancholy obſervation, that children often die ſtrangely and ſuddenly about theſe places. Philoſophical Collections, N° 2. p. 6.

The internal uſe of *lead* is dangerous on account of the colics and palſies that are occaſioned by it. Culinary veſſels, lined with a mixture of tin and lead, which is the uſual tinning, are apt to communicate to acid foods pernicious qualities, and require to be uſed with great precaution. The ſame thing has been alſo ſaid of liquors kept in glazed ware, and of cyder made in veſſels, where *lead* is uſed, and of wines adulterated with litharge, &c. See COLICA *Pictonenſium*.

Mr. Navier has lately diſcovered, that liver of ſulphur, and particularly liver of ſulphur of Mars, is an excellent antidote againſt the poiſon of *lead*; and he adviſes patients labouring under its pernicious effects to drink largely of acidulated liquors, to make afterwards the liver of ſulphur the principal part of the cure, and to finiſh the cure with gentle purgatives.

The

The Dutch have been charged with correcting the more offenſive expreſſed oils, as that of rape-ſeed, ſo as to ſubſtitute them for oil olive or oil of almonds, by impregnating them with lead: in order to detect this abuſe, mix a little of the ſuſpected oil with a ſolution of orpiment made in lime-water: on ſhaking them together, and ſuffering them to reſt, the oil, if it has any ſaturnine taint, will appear of an orange-red colour; if pure, of a pale yellowiſh. The *lead* is diſcovered in wines by the ſame ſulphureous ſolution, which changes the colour of wines impregnated with this metal to a brownish red or a blackiſh hue. However, the various preparations of *lead* are applied externally with ſafety and great benefit, on account of its ſedative, drying, and repellent qualities. The vinegar and ſugar of *lead*, and all the ointments and plaſters which contain ceruſs, minium or litharge, eminently poſſeſs theſe qualities. See the following articles and references.

For the laws relating to *lead*, and the ſtealing of it, ſee 27 Eli. III. ſtat. 2. c. 1. 3. 11: 38 Edw. III. ſtat. 1. c. 6. 4 Geo. II. c. 32. 29 Geo. II. c. 30.

LEAD, for the *manufacture of*, ſee PLUMBERY.

There are various preparations of *lead*, ſerving for various purpoſes.

LEAD, *baſſam of*, an external medicine, greatly famed for its effects in old and ſharp ulcers. It is made by mixing one ounce of ſugar of *lead* with two of oil of turpentine, and ſetting this mixture in a ſand-heat till the ſalt is diſſolved. By this means the oil acquires a red colour, and is called *baſſam of lead*.

LEAD, *burnt*, *plumbum uſtum*, is a chemical preparation uſed in medicine, made of plates of *lead* melted in a pot with ſulphur, and reduced by fire into a brown powder. *Lead* continued in fuſion and ſtirred, ſo that freſh ſurfaces may be expoſed to the air, will gradually change into a powdery duſky-coloured calx, bearing this name. *Burnt lead* is only intended for external uſe. It has the ſame virtues aſcribed to it, in ointments and plaſters, as litharge or minium. Mixed into an unguent with lard alone, it makes a good ointment for the piles.

LEAD, *butter of*, is a kind of liquid unguent made of vinegar and lead, incorporated with roſate oil, and commended for the cure of tetters. It is called *butyrum ſaturni*.

LEAD, *calcined*, or *calx of lead*. See CALX, CERUSSE, GLASS *of Lead*, LITHARGE, MASSICOT, MINIUM, *&c.*

LEAD, *caſting of*. See CASTING.

LEAD, *coheſion of*. See COHESION.

LEAD *duſt*, a preparation uſed by the potters; made by throwing charcoal duſt into melted *lead*, and ſtirring them a long time together; to ſeparate the coal again, they only waſh it in water, and dry it afreſh.—Its uſe is, to give a varniſh and gloſs to their works.

LEAD, *extract of*, or *Saturn*, is prepared by ſimmering together as many pounds of the LITHARGE of gold as quarts of vinegar for an hour and a quarter, and often ſtirring them; then taking it from the fire and, as ſoon as it is cool enough, pouring the clear liquor into bottles to be kept for uſe. If this liquor be made into the common conſiſtence of an extract, it muſt boil yet longer after its ſeparation from the maſs, and will acquire a reddiſh colour. This is Goulard's extract and the baſis of all his preparations of *lead*. It evidently differs in no reſpect from ſugar of *lead*, and vinegar of litharge, but in the degree of concentration. The only circumſtance in which the extract ſeems to have the advantage of ſugar of *lead*, appears to be in the greater quantity of the acetous acid contained in it, which proves an excellent antidote in many caſes, and the ſugar of *lead*, when once cryſtallized, cannot be brought back to that ſtate of ſolution in vinegar in which it was before; yet where a large quantity of watery menſtruum is added, as in Mr. Goulard's ſaturnine water, it is as well to make a ſolution of ſugar of *lead* in the water, and add the vinegar afterwards, as to mix them both together in the form of extract. Nikin's Obſ. on the external Uſe of Preparations of *Lead*, &c. p. 2. See VINEGAR *of Lead*.

LEAD, *glaſs of*. See GLASS *of Lead*.

LEAD, *marcaſſory of*, is the calx of *lead* purified and ſublimed. It is made of *lead* diſſolved in aqua fortis, pouring a filtrated ſalt water into it; whence reſults a magiſtery extremely white, which when ſoftened by ſeveral lotions, is mixed with pomatums for the face and complexion.

LEAD, *mock*, a name given to a glittering ſubſtance found in *lead*-mines. See GALENA *impura*, and BLENDE.

LEAD, *native*. See LEAD *ſupra*.

LEAD, *ointments of*, *preparations of*. See UNGUENT.

LEAD, *red*, a preparation of mineral *lead* calcined, and ruſſled; uſed by painters, potters, and ſurgeons. See MINIUM.

LEAD, *ſalt or ſugar of*, *ſaccharum Saturni*, is an eſſential ſalt of vinegar, incorporated with the proper ſubſtance of *lead*, or ceruſs, diſſolved in ſpirit of vinegar. See SACCHARUM *Saturni*.

LEAD, *tincture of*. See TINCTURA *Saturnina*.

LEAD, *vinegar of*, or of *litharge*. See VINEGAR.

LEAD, *water of*, *aqua Saturni*, is called by Mr. Goulard vegeto-mineral water, who makes it by dropping into a quart of pure water a hundred drops of the extract of ſaturn, and then adding to them four tea-ſpoonfuls of brandy. This is his ſpecific in external inflammations, particularly of the eye, for waſhing ulcers, cancers, ſcrophulas, contuſions, phlegmons, erypelas, piles, chilblains, tetters, gangrenes, *&c.* But a ſolution of the SACCHARUM *Saturni* will have the ſame effect.

LEAD, *white*. See CERUSSE.

LEAD *nails*. See NAILS.

LEAD, *black*, is a kind of mineral of a black or rather of a deep ſhining blue colour, but ſoft and unctuous, infomuch that it has been uſed, inſtead of oil or ſoap, to prevent the friction of machines, found chiefly in England, and appearing to be nothing elſe but a peculiar talcky earth. It is much uſed for pencils, or crayons for deſigning.

It is unfuſible by acids; unfuſible by fire, and in cloſe veſſels, reſiſts vehement degrees of it: but by long calcination in an open fire it is moſtly volatilized, emitting according to Lawſon, Diſſ. de Nihilo, inflammable blue flowers, and the reſiduum is a yellow calx, which being reduced by Mr. Quiſt, (ſee Swediſh Acts, 1754.) ſeemed to be a mixture of tin and iron. Hence it has been lately claſſed among the ſulphureous minerals, and called ſulphur ſatiated with iron and tin. Black *lead* in fine powder may be readily mixed with melted ſulphur, and though the compound remains fluid enough to be poured into moulds, it looks nearly like the coarſer ſorts of *black lead* itſelf. This was probably the method by which prince Rupert is ſaid to have made *black lead* run like a metal in a mould, ſo as to ſerve for *black lead* again. Birch's Hiſt. Royal Soc. vol. iii.

The German *black lead* pencils, and thoſe which are hawked about among us, are prepared in this manner: their melting or ſoftening, when held in a candle, or applied to a red-hot iron, and yielding a bluiſh flame, with a ſtrong ſmell like that of brimſtone, diſcovers their compoſition. Pencils of this kind are hard, and brittle, and cut or ſcratch the paper or wood inſtead of marking them. The true Engliſh pencils are formed of *black lead* alone, ſawed into ſlips, which are fitted into a groove made of the ſoftell wood, as cedar, and another ſlip of wood glued over them. Theſe pencils, however, are of different quality, on account of different ſorts of the mineral being fraudulently joined together in one pencil, the fore-part being commonly pretty good, and the reſt of an inferior kind. To avoid theſe inconveniencies, ſome take the finer pieces of *black lead* itſelf, which they ſaw into ſlips, and fix for uſe in port-crayons. Lewis's Commerce of Arts, p. 328.

The name ſeems given to this ſubſtance with ſome impropriety, the common *lead* being the true *black lead*, ſo called by way of contradiſtinction from tin, otherwiſe called *white lead*. Plott, in Phil. Tranſ. N° 240. p. 183. See LEAD and TIN. *Black lead* is otherwiſe popularly denominated *wad* or *wadd*, and *hollow*; by naturaliſts *wigrica fabrilis*, from its uſe in ſcoring; by analogy to the *rubrica fabrilis*, or rudile, which has the ſame uſe. Woodw. Meth. Foſſ. cl. 5. p. 43. See RUDDLE.

Black lead was known to the ancients under the names of *plumbago*, *galena*, and *molybdena*. Vide Ruland. Lex. Alchem. p. 370. voc. *Plumbago*. Caſt. Lex. Med. p. 355. voc. *Galena*. See PLUMBAGO, *&c.*

It is found in divers parts of Germany, *&c.* but the better ſort is the produce of England alone, and that reſtrained to the mines near Keſwick in Cumberland; beſides which, Dr. Woodward aſſures us, there is none found worth any thing in any other country. Woodw. Nat. Hiſt. Eng. Foſſ. tom. 1. p. 5.

It is ſomewhat difficult to aſcertain what claſs of minerals *black lead* belongs to. Metal it is not, as not being either ductile or even fuſible; nor can it be reckoned among ſtones, for want of hardneſs: it remains, therefore, that it muſt be placed among the earths, though it diſſolve not in water, as moſt earths will, except ſtiff clays and ochres; among the latter whereof Dr. Plott judges it may be reckoned, it ſeeming to be a ſort of cloſe earth, of very fine and looſe parts, ſo burnt as to become *black* and ſhining, diſcolouring the hands, as all ochres do. Whence the moſt proper name that can be given it, according to this author, is *ochra nigra*, or *black* OCHRE Phil. Tranſ. N° 240. p. 183.

Some writers ſpeak alſo of a factitious *black lead*, or *plumbago*, produced in furnaces, being found adhering to the ſides of thoſe where gold or ſilver are melted. Ruland. Lex. Alch. p. 373. voc. *plumbago*.

By

By our laws, entering mines of *black lead*, with intent to ſteal it, is made felony. See 25 Geo. II. c. 10. See LARCENY.

LEAD, in the *Manege*, is a term uſed to expreſs the part that begins any motion firſt. A horſe going in a ſtraight line always *leads*, or cuts the way with his right foot. This is called in French *entamer le chemin*.

LEAD-*walling*, in the *Salt-works*, on the ſalt-ſprings in ſome parts of England, is the term uſed for that quantity of brine that is neceſſary for twenty-four hours boiling in one houſe. The whole government of the works is in the hands of certain lords, who proportion the quantity to be worked by theſe *lead-wallings* to the ſeveral perſons who work it. At Namptwich, in Cheſhire, two hundred and ſixteen *lead-wallings* belong to all the owners of the pit, and no tradeſman, bachelor, or widow, can rent more than eighteen *lead-wallings*. All is under the direction of four ſworn officers, choſen every year, and theſe appoint how much ſalt ſhall be made each year, and how many houſes ſhall work at a time. Ray's Engliſh Words, p. 142.

LEADWORT, *plumbago*, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are theſe: the flower has a tubulous permanent empalement, which is indented at the top in five parts, and has one funnel-ſhaped petal, with a cylindrical tube, narrow at the top; the brim is cut into five oval parts, and it has five awl-ſhaped ſtamina, ſituated in the tube, ſitting upon the valves of the nectarium, which includes the germen; the ſmall oval germen ſuſtains a ſingle ſtyle, the length of the tube, crowned by a ſlender five-pointed ſtigma; the germen becomes a ſingle oval ſeed, included in the empalement. Miller enumerates two and Linnæus four ſpecies.

This is a plant ſeldom or never uſed, being of a hot, and even of a cauſtic nature, like pellitory of Spain, and has been made uſe of, like that, for the tooth-ach, and thence called *dentillaria* or tooth-wort.

LEADERS, in the *Military Art*. See FILE-*leaders*.

LEÆNA, the *lioneſs*. See LIONESS.

LEAF, *folium*, in *Botany*, a part of a plant, ordinarily very thin and flat, growing in the ſpring, and uſually falling off in autumn. See PLANT.

The *leaf* of a plant or tree is diſtinguiſhed from that of flowers: the firſt is called *folium* and the other *petalum*: in this article the term is uſed in the former ſenſe.

There are ſome plants without *leaves*, as truffles and muſhrooms.

As to the ſtructure of *leaves*, Dr. Grew obſerves, that their fibres never ſtand on the ſtalk in an even line, but always in an angular or circular poſture, and their vaſcular fibres or threads are 3, 5, or 7. The reaſon of which poſition is for their more erect growth, and the greater ſtrength of the *leaf*. Another circumſtance obſervable in the fibres of *leaves* is, their orderly poſition: ſo as in ſome to take in an eighth part of a circle, as in mallows; in ſome a tenth, but in moſt a twelfth.

The ſame author obſerves ſix ſeveral parts intended by nature for the preſervation of germs, viz. *leaves*, furfoils, interfoils, ſtalks of *leaves*, hoods, and mantlings that cover them.

The ſkin or coat of the *leaves* is no more than that of the branches extended, as gold, by beating, is reduced into *leaves*. In the germ, the *leaves* are folded, ſometimes in two, and ſometimes in ſeveral plaits, ſomewhat after the manner of a fan. If the leaves be too thick to plait commodiouſly in two, and to be ranged againſt each other; or if they be in too ſmall a number, and their fibres too delicate, inſtead of being plaited, they are rolled up, and form either a ſingle roll, as the *leaves* of the mountain cowſlip, which are thick; or two rolls, which begin at each extremity of the *leaf*, and meet in the middle. There alſo ſome plants, whoſe *leaves* form three rolls, as fern: ſeveral *leaves* are covered with hair of ſeveral figures; thoſe of lavender, and the olive-tree have hairs reſembling ſtars. See LANUGO.

Botaniſts have obſerved, that ſome plants have very thick fleſhy *leaves*, whoſe pulpy ſubſtance is always moiſt: theſe are ſuch as naturally grow upon dry barren rocks, and are generally natives of warm countries, which, as they can draw in very little nouriſhment from the earth, perſpire only in a ſmall quantity. The *leaves* of ſuch plants have a thin compact ſkin over their ſurface, with minute pores, which prevent the deſcending moiſture from penetrating into their ſubſtance and deſtroying them. The ſame ſtructure is alſo obſervable in the *leaves* of thoſe trees and ſhrubs, which retain their verdure all the year; and they are known to imbibe and perſpire little moiſture in compariſon with the deciduous trees and ſhrubs: moreover, their nutritive juices are of an oily exterior in their own quality, which ſecures them from the froſt. In all *leaves* there are two orders of veins or nerves, one belonging to each ſurface: thoſe on the under ſide of the *leaf* have their ramifications larger than thoſe on the upper. And the two orders of veins are inoculated in ſeveral places. Their uſes are ſuppoſed to be different: the upper laminæ are conceived to be air-veſſels or trachææ through which the perſpirable matter is diſcharged, which often appears in the form of HONEY-DEW, and the air is inſpired.

Plants are known to receive and tranſpire more, in equal time, than large animals; hence it appears, that the *leaves* are neceſſary to preſerve the plants in perfect health: becauſe it has been found by accurate calculation and repeated experiments, that a plant of the ſun-flower receives and perſpires in twenty-four hours, ſeventeen times more than a man.

The lower laminæ are deſtined, as it is imagined, for receiving, preparing and conveying the moiſture imbibed from the riſing vapours of the earth, by which trees and plants are greatly nouriſhed: ſo that one principal uſe of *leaves* is to perform, in ſome meaſure, the ſame office for the ſupport of vegetable life, as the lungs of animals do for the ſubſiſtence of animal life; plants drawing through their leaves ſome part of their nouriſhment from the air.

The *leaves* of plants are of the utmoſt conſequence to the life of the whole. Air evidently paſſes in at the *leaves*, and goes through the whole plant, and out again at the roots. If the *leaves* have no air, the whole plant will die, as is eaſily proved by the air-pump; but in theſe experiments, if the *leaves* be leſs on the outſide of the receiver, and parted by a hole cemented with wax, and have air, the plant will thrive, and grow, though its roots and ſtalk are kept in vacuo in water. The *leaves* of plants perform the neceſſary work of altering the water received in at the roots, into the nature of the juices of the plant; and hence it is, that the life of the plants depend ſo immediately on their *leaves*. The huſbandman often ſuffers for want of this knowledge. A crop of ſaint-foin is a very valuable thing, and its root being perennial, will yield him increaſe many years; but it is often deſtroyed at firſt, by ſuffering it to be indiſcreetly fed upon by the ſheep, which eating up all the *leaves*, the root remains without the means of a ſupply of air, and the whole periſhes.

Leaves being thus neceſſary to plants, nature has, in all perennial plants, provided a reverſionary ſtock of them. The *leaves* of theſe plants are always formed in autumn, though they are not unfolded till the following ſpring. They then open and increaſe gradually, in proportion to the motion of the ſap, and the quantity of pabulum it then receives to be circulated. Theſe *leaves* may alſo, though not wholly appearing out of the bud, be ſufficient for the extremely ſmall motion of life, which the ſap of perennial plants, that drop their leaves, has in winter. Tull's Horſe-hoeing Huſbandry, p. 19.

Dr. Grew obſerved the formation of theſe autumnal *leaves*; but beſide theſe, there is another ſet of them formed in the ſpring, and expanded about midſummer. Theſe are of infinite ſervice to many particular trees, particularly to the mulberry, as they ſave its life when the ſpring *leaves* have been all eaten up by the ſilk-worms. People who ſtrip that tree for the food of theſe animals find, however, that ſome caution is neceſſary, in order to make the new ſupply of ſpring *leaves* ſave the life of the tree. For if they pull off the old *leaves* downward, ſtripping away ſtalk and all, the tree often dies, but if they pull them upwards, the tree lives without hurt; becauſe the ſtalk, in this caſe, is left, and often a piece of the bottom of the *leaf* upon it. Theſe ſerve, in ſome degree, in the place of the whole *leaves*, till the new ones are formed.

It is certain that no plant, to which nature has allotted *leaves*, can live without them, but will certainly die if they are pulled off as ſoon as they appear. The common graſs of our meadows and paſtures might ſeem an exception to this general rule; but it is to be conſidered, that though the ſheep eat this down very cloſe, and take off its *leaves* as ſoon as they grow, yet when it is thus devoured by cattle, it is only in the *leaf*, very little of it growing up into ſtalk at that time, and therefore leſs ſap is to be purified, and conſequently leſs of the operation allotted to the *leaves* required; and there is a conſtant ſucceſſion of new *leaves* growing up in the place of the old ones, and many of theſe being too ſhort to be bitten off, ſerve in the place of thoſe which are eaten.

The *leaves* of trees and plants afford the curious in microſcopic obſervations many very beautiful objects.

All *leaves* are full of innumerable veſſels, which convey perſpirable juices to the pores for their diſcharge. Whether there be any circulation in them, is not yet determined; but as their juices all become ſtiff and congu-

lated;

lated, when let out, it is probable that they have some motion, which keeps them fluid while in the veſſels of the plant.

The pores in the *leaves* of plants are almoſt innumerable. Mr. Leewenhoek found an hundred and ſeventy-two thouſand and ninety pores on one ſide of a *leaf* of box. The *leaves* of rue ſeem full of holes, like a honey-comb; all the kinds of St. John's wort appear likewiſe ſtuck full of pin-holes to the naked eye, but the microſcope diſcovers, that the places where thoſe holes ſeem to be, are really covered with a very thin and white membrane. The backſide of the herb mercury looks, as if rough-caſt with ſilver, and all the ribs are full of white, round, tranſparent balls, faſtened by ſlender ſtalks, like ſo many grapes. A ſage-*leaf* appears like a rug, or thag, full of knots and tufts of ſilver thrums, and embelliſhed with fine round cryſtal beads, or pendants, and theſe faſtened by ſlender foot-ſtalks. The back-ſide of a roſe-*leaf*, and particularly of that kind called *ſweet-briar*, appears diaperred with ſilver. Every one knows, that the *leaves* of ſtinging nettles are thick ſet with ſharp prickles, which penetrate the ſkin when touched, and occaſion heat, pain, and ſwelling. Theſe ſymptoms were imagined formerly to be owing to the prickles being left in the wounds they make, but the microſcope diſcovers ſomething much more wonderful in this plant, and ſhews that its prickles are formed for acting, in the ſame manner as the ſtings of animals; for every one of them is found to be a rigid body, hollow, and terminating in a very fine point, with an opening near its end. At the bottom of this prickle there lies a pelluced bag, containing a limpid liquor, which, upon the leaſt touching the prickle, is ſquirted out at the little outlet, and if it enters the ſkin, produces the miſchiefs before mentioned by the pungency of its ſalts. And hence it is, that the *leaves* of nettles, when they have dried a little in the ſun, ſting ſcarce at all. Baker's Microſcope, p. 259.

Beſides, the *leaf* ſerves, in a ſingular manner, to nouriſh the eye or germ of the plant, until, growing by degrees to a greater bulk, it preſſes the veſſels of the foot-ſtalk together, whereby the juice is by little and little ſtopped in the *leaf* till it cannot any more return through the foot-ſtalk; which, by the ceſſation of the afflux and reflux of the nutritious juice, grows putrid, and the *leaf* dies and falls off; which is the chief cauſe of the falling of the *leaves* in autumn. *Leaves* likewiſe ſhade the buds for the future ſhoots from the ſun, which would otherwiſe exhale and dry up their moiſture, and alſo the young fruit. Miller. See *Perſpiration of* PLANTS.

Botaniſts conſider the *leaves* of plants, with regard to their ſtructure, ſurface, conſiſtence, edges, ſituation, ſize, and figure. With regard to their ſtructure, *leaves* are either ſingle, as thoſe of the apple-tree, pear-tree, *&c.* or *double*, as thoſe of angelica, parſley, *&c.*

With regard to their ſurface, *leaves* are either *flat*, as the nummularia, aſarum, origany, *&c.* or *hollow*, as thoſe of the onion and aſphodel; or thick and ſolid, as ſeveral kinds of kali, and houſe-leeks.

With regard to their conſiſtence, *leaves* are either *thin* and fine, as thoſe of St. John's-wort, and dog's-graſs; or *thick* and groſs, as thoſe of portulaca; or *fleſhy*, as thoſe of ſeveral kinds of houſe-leeks; or *woolly*, as thoſe of the mullein.

With regard to the verge, or edges, *leaves* are either *cut ſlightly*, as ſome ſpecies of geum, and cannabis; or *deep*, as treſoil, *&c.*

With regard to their ſituation, *leaves* are either *alternate*, that is, ranged alternately, as the hounds-tongue; or oppoſite to each other, as the phillyrea; or ſtellated, as in the rubia. With regard to their ſize, *leaves* are either very *big*, as thoſe of the colocaſia, and ſphondylium; *moderate*, as thoſe of the fig-tree; *ſmall*, as thoſe of the apple-tree, pear-tree, peach-tree; or *very ſmall*, as thoſe of the mille-pertuis, or St. John's wort.

The figure of the *leaves* of plants may be repreſented by holding one to the ſmoke of reſin, camphor, a candle, *&c.* whereby the *leaf* acquires a blackneſs, which, when preſſed on white paper, gives the exact ſize, ſhape, and particular ramifications of the fibres. This method may be of uſe to botaniſts, when they have no ſkill in drawing. Boyle's Works abr. vol. i. p. 132.

The *leaves* of plants have ſeveral diſtinctions among botaniſts, according to their ſhape and diviſion, each of which has its peculiar name. See *Tab. of Leaves, Botany, Tab.* III. and IV.

Leaves are uſually divided into *ſimple* and *compound*, to which ſome alſo add *determinate*; each of which has its ſeveral ſubdiviſions.

LEAF, *acerous*, is a ſimple linear *leaf*, which ſtays on the tree, and is ever-green; as in the fir, yew, *&c.*

LEAF, *acinaciform*, or *ſcimitar-ſhaped*, is a ſimple *leaf*, which is fleſhy and compreſſed, with one of its edges convex and narrow, the other thick and ſtrait.

LEAF, *aculeated*, is a ſimple *leaf*, whoſe ſurface is covered with cartilaginous points, ſharp, rigid, and ſtrong enough to wound any tender part of the fleſh; and which adhere but ſlightly to the *leaf*, and may be eaſily ſeparated from it.

LEAF, *acuminated*, a ſimple *leaf*, terminated by a pointed and ſharp extremity, like an awl.

LEAF, *acute*, a ſimple *leaf*, which terminates in a ſharp point.

LEAF, *adpreſſ*, *folium adpreſſum*, is when the diſk of the *leaf* lies cloſe to the ſtem.

LEAF, *adverſe*, is one whoſe ſides reſpect the meridian, and not the heavens, as ginger.

LEAVES, *alated*, are thoſe divided into, or compoſed of ſeveral complete pinnated *leaves*, whether equal or unequal, uniform or diſform, as in the orobus, and other the like plants.

LEAVES, *alternate*, thoſe which do not ſtand oppoſite, but one over another, all the way up the ſtalk.

LEAF, *amplexicaule*, expreſſes a *leaf*, the baſe of which extends itſelf in ſuch a manner, that it environs and ſurrounds the ſtalk every way. In this caſe, the *leaf* is generally of a ſagittated, or heart-faſhioned ſhape, and is ſeſſile.

LEAF, *articulated*, is a compound *leaf*, formed by one growing on the top of another.

LEAF, *axillary*, is a determinate *leaf*, that grows from the inſertion of the branches.

LEAF, *bifid*, one divided into two parts at the top. When a *leaf* is thus divided into three parts, it is ſaid to be *trifid*; when into four, *quadrifid*, and ſo on. *Multifid* expreſſes a *leaf* divided into a great number of ſegments.

LEAF, *bigeminate*, a compound *leaf*, formed of a double conjugation of leſſer *leaves*; or one whoſe foot-ſtalk divides in parts, and connects four ſmall *leaves* on the top.

LEAF, *binated*, *binatum folium*, a kind of compound *leaf*, formed only of two folioles on one petiole.

LEAF, *bipartite*. See *Quinque partite* LEAF, infra.

LEAF, *canaliculated*, a ſimple *leaf*, which is hollowed all the way of its length with a channel.

LEAF, *carinated*, or *keel-ſhaped*, is a ſimple *leaf*, that has the under part of the diſk prominent through the whole length, and the upper concave, like the keel of a boat.

LEAF, *carnoſe*, a ſingle *leaf*, which is full of pulp, or of a fleſhy ſubſtance, contained between the membranes which form the upper and under ſurface.

LEAF, *cartilaginous*, a ſimple *leaf*, whoſe edge is ſurrounded with a kind of cartilage or border, thicker than the reſt, but of a different ſubſtance from the *leaf*.

LEAF, *cauline*, a determinate *leaf*, which grows not immediately from the root, but on the ſtalk of a plant.

LEAF, *ciliated*, a ſimple *leaf*, ſurrounded all the way with parallel hairs, or filaments, ſo as to give ſome reſemblance of the hairineſs of the eye-lids.

LEAF, *cirroſe*, or *cloſper*, is a ſimple *leaf*, that terminates with a cloſper or tendril.

LEAF, *clavate*, *folium ſiſſum*, a ſimple *leaf*, divided by linear ſinuſſes, and ſtrait margin; from the number of which diviſions they are called bifid, trifid, *&c.*

LEAF, *colowred*, is that which has other colours than green.

LEAF, *compound*, is that which is divided to the middle rib into ſeveral ſegments, and ſeems made up of ſeveral ſmaller *leaves*, as in liquorice, *&c.*

Compound leaf expreſſes, in general, a *leaf* that is formed of ſeveral other leſſer ones, ſtanding upon the ſame foot-ſtalk. In this large ſenſe, however, it is diviſible into ſeveral kinds. 1. The *compound one*, properly and diſtinctly ſo called. 2. The *decompound*. And, 3. The *ſuperdecompound*. Of each of which in its place.

In deſcribing theſe kinds of *leaves*, the whole *leaf*, which is the reſult of the combination, is called *folium*, and the ſmall *leaves*, which together compoſe it, are called *foliola*.

Compound leaf, properly ſo called, is only formed of one ſeries of folioles, or of one compoſition.

LEAF, *compreſſed*, a ſimple leaf, whoſe marginal ſides are ſo preſſed, that the ſubſtance of the *leaf* is larger than the diſk.

LEAF, *concave*, a ſimple *leaf*, whoſe middle is ſunk or hollowed.

Conferta FOLIA, *leaves* placed in cluſters, or ſo cloſe to one another, that it is not eaſy to diſcover their exact ſituation.

LEAF, *conjugate*, is a compound pinnate *leaf*, conſiſting of two folioles only.

Connata FOLIA, *leaves* cohering together, or whoſe baſes unite, ſo as to form but one body.

LEAF, *convex*, a ſimple *leaf*, whoſe middle riſes into a protuberant form.

LEAF, *cordated*, expreſſes a ſimple *leaf* of an ovated ſhape, hollowed a little on each ſide at the baſe, but without any angles.

LEAF, *obversely-cordated*, one of the same figure with the former, but affixed to its petiole not by the cordated part, which is the base in the former, but by the opposite end.

LEAF, *cordato-sagittated*, a *sagittated leaf*, the sides of which are convex.

LEAF, *crenated*, *crenatum folium*, a simple *leaf*, whose edges are furnished with indentings, which are contiguous to one another, and are neither turned toward the point, nor toward the base.

LEAF, *acute-crenated*, a *crenated leaf* in which the indentings are sharp at the ends.

Obtuse-crenated, that whose indentings terminate obtusely.

LEAF, *crisp*, *crispum folium*, a simple *leaf*, which is undulated or folded over and over at the edge, which must also be in some manner divided, not entire, viz. either dentated, serrated, or lacerated.

LEAF, *cuneiform*, is a simple *leaf*, of the shape of a wedge; or the length of which greatly exceeds its breadth, and the lower part of which grows smaller all the way.

LEAF, *decompofite*, expreſſes a compound *leaf*, the common petiole of which divides itſelf twice before it is furniſhed with *leaves*.

LEAF, *decurrent*, one which adheres immediately to the ſtalk or branch of a plant, without any pedicle; and which has its lower part extended and running along the branch.

LEAF, *deltoide*, a ſimple *leaf* with four angles, whereof thoſe of the ſummit are farther diſtant from the center than thoſe of the ſides.

LEAF, *demerſe*, is one which is hid beneath the ſurface of the water.

LEAF, *dentated*, a ſimple *leaf*, whoſe edge is beſet with horizontal points of the ſame matter with the *leaf* itſelf, and diſtinct and ſeparate one from another.

LEAF, *dependent*, is one whoſe ſummits point to the ground.

LEAF, *depreſſed*, is a ſimple *leaf*, whoſe diſk is more depreſſed than the ſides.

LEAF, *determinate*, is that which derives its character from ſome circumſtance foreign to its own particular ſtructure or configuration, as from its place, ſituation, inſertion, or direction.

LEAF, *digitated*, expreſſes a compound *leaf*, formed of a number of ſimple foliola, placed regularly on a common petiole. In a ſtrict ſenſe, however, it is uſed only to expreſs ſuch a *leaf* as is compoſed of more than four foliola.

LEAVES, *diſſect*, are thoſe which are ranged along only upon two ſides of the branches, as in the fir-tree.

LEAF, *dolabriform*, or *hatchet-ſhaped*, is a ſimple *leaf*, which is roundiſh, compreſſed, and obtuſe, gibbous on the outſide, the inſide ſharp-edged, and taper below.

Duplicato-pinnatum, or *pinnato-pinnatum*, expreſſes a *leaf* compoſed of ſeveral others, each of which is itſelf compoſed of ſeveral ſmaller *leaves* or foliola.

LEAF, *duplicato-ternated*, a compound *leaf*, conſiſting of *leaves*, which are themſelves compoſed of three *leaves* each.

LEAF, *emarginated*, a ſimple *leaf*, which has a little indenting on the ſummit. *Obtuſely emarginated*, is the term when the two points which form the indenting are obtuſe. When they are acute, it is ſaid to be *acutely emarginated*.

LEAF, *enſiform*, a compreſſed ſimple *leaf* of the ſhape of a ſword, which is thin, and edged, as it were, on the ſides, and which has a high rib running down its middle.

LEAF, *erect*, one ſo ſituated as to make an acute angle with the ſtalk.

LEAF, *erode*, *eroſum folium*, a ſimple *leaf*, which has ſeveral ſinuſes in its diſk, and alſo in the edge or border.

LEAVES, *faſciculate*, expreſs *leaves*, many of which ariſe together from the ſame point.

LEAF, *floral*, expreſſes one found near the flower, and which never appears but with the flower.

Frondes expreſs *leaves* conſiſting of ſeveral other *leaves*, and forming the whole plant; as in the caſe in the fern-kind, in which the fructification being on the back of the *leaves*, the ſingle *leaf* makes the whole plant.

LEAF, *gibbous*, is a ſimple *leaf*, which is convex on both ſides, the middle being fuller of pulp.

LEAF, *haſtated*, a ſimple *leaf*, in form like a ſpear's point. This expreſſes a triangular *leaf*, the ſides and the baſe of which are both hollowed, ſo as in ſome meaſure to give the reſemblance of a *leaf* compoſed of three parts.

Hirſutum folium. See *Piloſe* LEAF, infra.

LEAF, *hiſpid*, a ſimple *leaf*, whoſe ſurface is covered with more thick and rigid hairs than the *piloſe* LEAF.

LEAF, *horizontal*. See *Patent* LEAF, infra.

LEAF, *jagged*. See *Laciniated* LEAF, infra.

LEAVES, *imbricated*, *imbricata folia*, *leaves* placed over one another in the manner of the tiles of a houſe, or like the ſcales of fiſhes.

LEAF, *inflex*, *inflexum folium*, that which in growing from its baſe, turns its point again toward the plant.

LEAF, *intire*, *integrum*, or *indiviſum folium*, a ſimple *leaf*, which is not cut in with any ſinus in its diſk.

The term *integerrimum* applied to a *leaf*, denotes that it is free from all diviſions or indentations of any kind in the border any more than in the diſk.

LEAF, *lacerated*, *lacerum folium*, a ſimple *leaf*, the edge of which is compoſed of ſegments of different ſhape and figure.

LEAVES, *lacinulated*, are ſimple *leaves*, which are very deeply cut in, though not quite to the middle rib, yet are divided into ſeveral jagged portions: theſe are called alſo jagged *leaves*; and of this kind are thoſe of the horned-poppy, ragwort, and the like.

LEAF, *lanate*, or *woolly*, is a ſimple *leaf*, whoſe ſurface is covered with a kind of woolly ſubſtance, like the fleece wool of lambs.

LEAF, *lanceolated*, a ſimple *leaf*, which is ſhaped like a ſpear's point, or which is oblong, and growing ſmaller and narrower from the middle to the extremity, where it terminates in a point.

LEAF, *linear*, a ſimple *leaf*, the two ſides of which run almoſt parallel to one another: the *linear leaves* are uſually narrow, and ſomewhat broader in the middle than at either end.

LEAF, *linguiform*, a ſimple linear *leaf*, in ſhape of a tongue, which is obtuſe, fleſhy, depreſſed, convex on the under ſide, and uſually cartilaginous at the edge.

LEAF, *lobated*, is a ſimple *leaf*, divided to the middle into parts that ſtand wide from each other, and have their margins convex. From the number of theſe lobes they are called *bilobe*, *trilobe*, &c.

LEAF, *lunulated*, a ſimple *leaf*, in form of a creſcent: it is a ſuborbicular *leaf*, hollowed at the baſe, with two curvilinear angles in form of ſickles at its hinder part or baſe.

LEAF, *lyrated*, *folium lyratum*, a ſimple *leaf*, in form of a lyre; or it is a *leaf*, which divides itſelf in its lower part in ſuch a manner, that the inciſions below make ſegments, which ſtand out from the body of the *leaf*, and are detached from the larger ſegment, which forms the upper part.

LEAF, *membraneous*, a ſimple *leaf*, merely compoſed of membranes, with no pulp between.

LEAF, *naked*, *nudum folium*, expreſſes a *leaf*, whoſe ſurface is ſmooth and equal, without any particular marks.

LEAF, *natant*, one which floats upon the ſurface of the water.

LEAF, *nervoſe*, a ſimple *leaf*, whoſe veſſels are ſimple, and extend themſelves parallely from the baſe toward the ſummit, without any ramifications.

Nitidum folium, expreſſes a ſimple *leaf*, of a ſmooth and gloſſy ſurface, looking as if poliſhed by art.

LEAF, *oblique*, is one whoſe baſe regards the ſky, and ſummit the horizon.

LEAF, *oblong*, a ſimple *leaf*, the length of which is many times equal to its breadth, and the extremities of which are both too narrow to form ſegments of circles.

LEAF, *obtuſe*, a ſimple *leaf*, terminated by the ſegment of a circle. When the ſummit of a *leaf* is obtuſe, but terminated by a ſharp point, affixed, as it were, upon it, it is ſaid to be *obtuſum cum acumine*.

LEAF, *obverſely-ovated*, *obverſe ovatum folium*, a *leaf* of the ſame figure with the ovated *leaf*, only fixed to the petiole by its ſmaller end.

LEAVES, *oppoſite*, are thoſe which ſtand by pairs on each ſide of the ſtalk.

LEAF, *orbiculate*, a ſimple *leaf* of a round figure, the breadth of which is equal to its length, and every part of its edges equally diſtant from the center.

LEAF, *oval*, a ſimple *leaf*, approaching to round, but too long for its breadth; its two ends forming the ſame ſegments of circles. This might be more diſtinctly called *elliptic*.

LEAF, *ovated*, *folium ovatum*, expreſſes a ſimple *leaf*, the ſhape of which is like that of an egg, or which is longer than broad, and the baſe or lower part of which forms the ſegment of a circle, though the other extremity is too ſmall to be in proportion to it.

LEAF, *palmated*, a ſimple *leaf*, in form of an open hand. This expreſſes a *leaf*, divided into ſeveral ſegments, from the top down to the middle, or to the baſe.

LEAF, *panduriform*, one of the ſhape of a violin. This is an oblong *leaf*, larger at both ends than in the middle, where it is deeply cut, in a rounded manner.

LEAF, *papillofe*, a ſimple *leaf*, whoſe ſurface is covered with little roundiſh protuberances, or veſicles.

LEAF, *parabolical*, is a ſimple *leaf*, whoſe length exceeds its breadth, and is narrowed from the baſe upward.

LEAF, *partite*, or *divided*, is a ſimple *leaf*, divided into many parts to the baſe, ſo as to appear like many *leaves*, till they are examined. From the number of diviſions they are bipartite, tripartite, &c.

LEAF,

LEAF, *patent*, one which ſtands almoſt ſtrait out from the ſtalk, or nearly at right angles with it. When it forms perfectly right angles, it is called *horizontal*.

LEAF, *pedate*, or *footed*, a compound *leaf*, whoſe foot-ſtalk or petiole is divided, and has ſome ſmall *leaves* placed on the inner ſide.

LEAF, *peltated*, expreſſes a *leaf*, the petiole of which is affixed to the diſk, and not to the baſe, or to the edge of the *leaf*.

LEAF, *pentagonal*. See *Trigonal* LEAF, infra.

LEAF, *perfoliate*, that whoſe diſk is pierced by the ſtalk, the branch, or the peduncle; and does not any where touch or adhere to its edges.

LEAF, *petiolate*, one affixed to a plant by means of a peculiar pedicle, which in the caſe of a *leaf* is called *petiole*, though in caſe of fruit a *peduncle*. See PETIOLE, &c.

LEAF, *pilоſe*, a ſimple *leaf*, whoſe ſurface is furniſhed with hairs ſo large and long, as to be diſtinguiſhable by the eye ſeparately. A *leaf* hairy to a greater degree is expreſſed by the term *hirſutum*; and when it is covered with a coarſer hair or ſhag, *villoſum*; and with a ſhorter and finer, *lanigerum*.

LEAF, *pinnated*, or *pennated*, a compound *leaf*, formed in manner of a wing, and compoſed of two ranges or ſeries of ſoliоles, annexed to the two ſides of one common oblong petiole.

Of the *pinnated leaves* there are ſeveral kinds.

Pinnate with an odd one, when it is terminated by an odd ſoliole; *cirrhoſe pinnate*, when it terminates in a cirrhus or claſper; *abrupt pinnate*, when it is terminated neither by a ſoliole nor cirrhus; *oppoſitely pinnate*, when the ſolioles ſtand oppoſite to each other; *alternately pinnate*, when the ſolioles are produced alternately; *interruptedly pinnate*, when they are alternately leſs; *articulately pinnate*, when the petiole common to all the ſolioles is articulate or joined; *decurſively pinnate*, when the ſolioles are decurrent, or extend themſelves downwards along the petiole.

LEAF, *pinnatifid*, expreſſes a ſimple *leaf*, divided into ſeveral parts, in form of ale's, or which has three, four, or more lateral ſinuſes, ſeparated by long horizontal ſegments.

LEAF, *plane*, is a ſimple *leaf*, which has both ſurfaces every where parallel.

LEAF, *plicated*, a ſimple *leaf*, from the baſe or petiole of which there run at ſeveral diſtances veſſels or fibres, which extend themſelves to the extreme ſides, and ſome of which raiſe and others depreſs the diſk of the *leaf* in an alternate order, making acute angles.

LEAF, *præmorſe*, *præmorſum folium*, a ſimple *leaf*, which is truncated and terminated by very blunt unequal cuts.

LEAF, *punctated*, or *dotted*, is a ſimple *leaf*, beſprinkled with hollow points or dots.

LEAF, *quadrangular*, is a ſimple *leaf*, with four prominent angles round the diſk.

LEAF, *quadrifid*. See *Bifid* LEAF.

LEAVES, *quaternate*. See *Ternate* LEAF.

Quina FOLIA. See *Ternate* LEAF.

LEAF, *quinquangular*, a ſimple *leaf*, with ſtrait ſides, and five angles.

LEAF, *quinquefoliate*, is a compound *leaf* of the ſame form with the *trifoliate*, but made up of five ſegments; ſuch are the *leaves* of cinquefoil, &c.

LEAF, *quinqueſeparatite*, one which is ſeparated into five parts down to the very baſe, ſo as to ſeem made up of five ſeparate *leaves*, till cloſely examined. In the ſame manner a *leaf* is ſaid to be *bipartite*, &c. when it is divided into two, three, &c. parts.

LEAF, *radical*, a determinate *leaf*, which grows immediately from the root of a plant, not from the ſtalk.

LEAF, *radicant*, one which puſhes out roots from its ſummits, as ſome of the ferns do.

LEAF, *radicated*, *ſolium radicatum*, one which puſhes out roots from its diſk or lower ſurface.

LEAVES, *ramoſe*, thoſe which are ſtill more divided than the winged or alated *leaves*, and compoſed of one ſeries farther in their diviſion. Of this ſort are the *leaves* of female fern, and the like. Or,

Ramoſe leaf is a *leaf* of the claſs of determinate *leaves*, which grow not on its main ſtalk, but on its branches.

LEAF, *ramuloſe*, a kind of compound *leaf*, in which there are ſeveral ſolioles ſaſtained on a branched petiole.

LEAF, *reclinate* or *reflex*, one which has its ſummit lower than its baſe.

LEAF, *reniform*, a ſimple *leaf* of the ſhape of a kidney; or, is a *leaf* of a ſubcircular figure, hollowed a little at the baſe, but without any angle.

LEAF, *repandous*, *ſolium repandum*, a ſimple *leaf*, the border of which is marked all round with ſhort lobes, each making a ſegment of a circle, with obtuſe ſinuſes.

LEAF, *retuſe*, *retuſum folium*, a ſimple *leaf*, whoſe extremity is terminated by an obtuſe ſinus.

LEAF, *revolute*, *folium revolutum*, a *leaf*, the upper part of which rolls itſelf downward.

LEAF, *round*, *teres folium*, a ſimple *leaf*, which is not flatted as moſt are, but is of a cylindric figure, except the point. A *round leaf* denotes alſo one that has no angles.

LEAF, *rugoſe*, a ſimple *leaf*, whoſe veins are ſunk deep, and between which the membranous and fleſhy part of the *leaf* riſes in irregular forms, ſo as to give upon the whole a wrinkled ſurface.

LEAF, *ſagittated*, a ſimple *leaf*, formed like the iron head of an arrow. This is the triangular *leaf*, hollowed at its baſe for the inſertion of the petiole.

LEAF, *ſalbrous*, a ſimple *leaf*, which has ſeveral irregular prominences on its ſurface.

LEAF, *ſemamplexicaule*, one reſembling the *amplexicaule*, but with its lobes at the baſe too ſmall to entirely ſurround the ſtalk.

LEAF, *ſemicylindric*, is a ſimple *leaf*, which is round on one ſide, and flat on the other.

LEAF, *ſeminal*, a determinate *leaf*, which appears firſt from the ſeed of a plant, and is uſually different from the reſt.

LEAF, *ſerrated*, *folium ſerratum*, a ſimple *leaf*, whoſe edge or border is notched like a ſaw, or furniſhed with points which make acute angles, and placed one bending toward another, and all toward the top.

Retroverſum ſerratum folium, expreſſes a *leaf*, whoſe edge is furniſhed with the ſame ſort of indentings, but in which they are turned backwards, or all look toward the baſe of the *leaf*.

Obſolete ſerratum folium, expreſſes a *leaf* indented in the ſame manner, but the indentings obtuſe and weak.

Folium duplicato-ſerratum, denotes a *leaf ſerrated* as the firſt, but with the ſerratures large, and their edges *ſerrated* again with indentings of the ſame kind.

LEAF, *ſeſſile*, one which riſes immediately from the ſtalk, without any pedicle.

LEAF, *ſimple*, is that which is whole, or not divided to the middle rib, or ſeeming made up of different ſmaller *leaves*; as in ſage, mint, &c.

Simple leaf is otherwiſe defined, that of which the PETIOLE carries only one.

LEAF, *ſinuated*, a ſimple *leaf*, which has a number of ſinuſes on its ſides, but theſe ſeparated by lobes not very long, nor themſelves indented or notched at the edges.

Sinuate-dentated leaf, expreſſes a *leaf* like the former, but with the lateral lobes of a linear figure.

Retroverſum ſinuatum folium, a *leaf* with ſinuſes at the ſides, and with the lobes which divide them, pointed and turned toward the baſe, like the barbs of an arrow.

LEAF, *ſmooth*, *folium glabrum*, is that whoſe ſurface is ſmooth, and has no inequalities.

LEAVES, *ſparſe*, thoſe which are placed irregularly over the ſeveral parts of the plant.

LEAF, *ſpatulated*, is a ſimple *leaf*, of a roundiſh figure, but narrow at the baſe, and linearly lengthened.

LEAF, *ſpinoſe*, a ſimple *leaf*, whoſe diſk or edge is armed with cartilaginous points ſo firmly affixed, that they cannot be ſeparated without injuring the *leaf* itſelf: to which is oppoſed an unarmed or ſmooth *leaf*.

LEAVES, *ſtellate*, thoſe which grow more than ſix at a joint, and are arranged like the rays of a ſtar, called alſo *verticillate* or whorled.

LEAF, *ſtriated*, a ſimple *leaf*, with a number of longitudinal furrows on its ſurface.

LEAF, *ſubrotund* or *roundiſh*, a ſimple *leaf*, approaching to the figure of the orbicular *leaf*, but departing from it, either in being too long or too broad, or prominent, in ſome one or more parts.

LEAF, *ſubulate*, that which grows at the ramifications, or under that part of the ſtalk, from whence there grows one or ſeveral branches.

LEAF, *ſubulated*, is a ſimple *leaf*, of the ſhape of an awl. This expreſſes a *leaf* oblong and narrow, broadeſt at the baſe, and thence gradually decreaſing, till it terminates in a point.

LEAF, *ſulcated*, a ſimple *leaf*, which has a great number of ridges all round it, with obtuſe ſinuſes.

LEAF, *ſupradecompoſite*, a compound *leaf*, which has the common petiole divided more than twice, before it is charged with *leaves* or ſolioles.

LEAF, *ternated*, a compound one, conſiſting only of three *leaves* on a common petiole.

Ternate alſo expreſſes *leaves* which grow three at a joint, ſurrounding the ſtalk. When there are four or five, they are called *quaterna* and *quina*, and ſo on.

LEAF, *tetragonal*. See *Trigonal* LEAF, infra.

LEAF, *tomentoſe*, a ſimple *leaf*, whoſe ſurface is covered with hairs ſo ſhort and fine, that the eye does not diſtinguiſh them ſingly, though the *leaf* in general is evidently downy, both to the ſight and the touch.

LEAF, *triangular*, a ſimple *leaf*, compoſed of three reſti-

linear sides, and three angles, the two inferior ones of which are on a level with the base.

LEAF, *trifid*. See *Bifid* LEAF.

LEAF, *trifoliate*, is a compound *leaf*, made up of segments, placed in the same order as in the digitated *leaf*; but these segments are usually short, and are always three in number. Of this sort are the *leaves* of clover, grass, &c.

LEAF, *triganal*, a simple *leaf*, much like the triquetrous, only that in this the several faces are each hollowed in form of channels, and the ribs are sharp and membranaceous.

A *leaf* that has, instead of three ribs or edges, four or five, is in the same manner called *tetraganal*, *pentaganal*, &c.

LEAF, *trilobous*, one divided into three lobes. This is a *leaf* divided just down to the middle into three parts, which stand apart from one another, and are rounded at the edges.

LEAF, *triportite*. See *Quinqueportite* LEAF, supra.

Tripennate, or *tripinnate-pinnate*, is a compound *leaf*, whose petiole bears many folioles, each of which are bipinnate.

Tripinnate-ternatum, or *ternate-ternatum*, a compound *leaf*, the petiole of which divides three times into three branches, before any *leaves* or folioles are placed on it.

LEAF, *triquetrous*, expresses a simple *leaf*, which has three faces or sides, all flat. This is usually also foliulated, or grows smaller gradually from the base to the point.

LEAF, *truncated*, a simple *leaf*, whose summit or point seems to have been cut off, or is terminated by a strait line in a transverse direction.

LEAF, *tubulose*, a simple *leaf*, which is hollow within, and makes a kind of tube.

Vaginans expresses a *leaf*, the base of which is formed like a cylinder, and surrounds the stalk, as is the case in many of the grasses.

LEAF, *vessie*, a simple *leaf*, on the surface of which there are a vast number of branched vessels, which frequently unite in an odd manner one with another.

LEAF, *villose*. See *Pilose* LEAF, supra.

LEAF, *viscous*, is a simple *leaf*, which has its surface covered with a clammy moisture, that is not fluid.

LEAF, *undulated*, a simple *leaf*, whose exterior part of the disk is of more extent than a circle of the same diameter, so that the edges are necessitated to rise and fall in a regular manner.

The following remarks concerning the colouring substances of *leaves* are taken from Dr. Lewis. The green colour of the leaves of plants may be extracted by rectified spirit of wine and by oils. The spirituous tinctures are generally of a fine deep green, even when the *leaves* themselves are dull coloured, or yellowish, or hoary. The colour however seldom remains long in these liquors; and it remains a much shorter time when the colouring matter is separated in a solid form, and exposed to the air. The acanthus gives a more durable green colour to spirit than any other herb. Alkalis heighten the colours of the tinctures and of the juices; and acids weaken, destroy, or change them to a brownish colour. Lime-water improves the colour, and also the durability of the colour. By means of lime, not inelegant green lakes may be obtained from the leaves of acanthus, lily of the valley, and of several other plants. Few herbs communicate any part of their green colour to water; perhaps none give a green considerably deep. Nevertheless, a green dye is said to be given to woollen by the leaves of some plants, as of the wild chervil, or cow-weed, the common rag-wort, and devil's-bit. The leaves of many kinds of herbs and trees give a yellow dye to wool, previously boiled in a solution of alum and tartar. Weld particularly affords a fine yellow dye. Mr. Hellot observes, that all *leaves*, barks, and roots, which have an astringent taste, as the *leaves* of the almond, peach, and pear-trees, alh-bark, roots of wild patience, &c. yield durable yellows. From the *leaves* of two plants, blue colouring substances are produced, namely, INDIGO and WOAD. Mr. Hellot suspects that a similar blue feccula might be produced from many other vegetables. He supposes the green colour of vegetables to proceed from a mixture of blue and yellow particles, and that the former are frequently more permanent than the latter, so as to be capable of resisting the fermentation of the juice of the plants, while the yellow are destroyed by that fermentation. Dr. Lewis has tried, without success, to obtain blue dyes from other plants, by putrefying them in water.

LEAF, *Indian*, in *Botany*. See TAMALAPATRA.

LEAF, *water*, in *Botany*, *hydrophyllum*, a genus of the *pentandria monogynia* class. Its characters are these: the flower has a permanent empalement of one leaf, cut into five segments; it has one bell-shaped petal, divided into five parts; under each of these segments is fixed a nectarium, which is situated about the middle: it has five stamina, which are longer than the petal, and an oval pointed germen, which becomes a globular capsule with one cell, including one large round seed. We know but one species, which grows naturally in boggy grounds in North America. Miller.

Linnæus reckons two species, one growing in Virginia, and the other in Canada.

LEAF is also applied to the finest and most beautiful parts of flowers, more properly called *petals*.

It is true, all flowers have not *leaves* or petals; and it is sometimes difficult to determine which is to be called the *leaves*, and which the calyx of the same flower.

To prevent confounding the *leaves* of the flower with those of the rest of the plant, the former are called by botanists *petals*, the latter *folia*.

LEAVES, in *Architecture*, are an ornament of the Corinthian capital, and thence borrowed into the Compositе; consisting in the representation of a double row of *leaves* covering the vase, tympanum, or neck of the column.

These *leaves* are usually formed in imitation of those of the acanthus; sometimes of those of olive, and sometimes of laurel.

The *leaves* are divided; each making three ranges of lesser, and are bent atop, one third of their height.—*See Tab. Archi. fig.* 28.

LEAF-*gold*. See GOLD-*leaf*.

LEAVES in clocks and watches, are used for the notches of their PINIONS.

LEAD-*silver*. See SILVER.

LEAGUE, an extent of ground, considered lengthwise; serving to measure the distances of one place from another; and containing more or less geometrical paces, according to the different usages and customs of countries.

The word comes from *leuca*, or *lega*, an ancient Gaulish word, for an itinerary measure, and adopted in that sense by the Romans. Some derive the word *leuca* from *leuca*, white; because the Gauls, in imitation of the Romans, marked the spaces and distances of their roads with white stones.

A *sea-league*, is usually reckoned 3000 geometrial paces, or three English miles; the large *leagues* of France are usually 3000, and in some places 3500 paces: the mean or common *league* is 2500 paces, and the little *league* 2000. Cluver observes, that the ancient Gaulish *leagues* were but 1500 paces.

The Spanish *leagues* are larger than the French, 17 Spanish *leagues* making a degree, or 20 French *leagues*, or 69½ English statute miles. The *leagues* of Germany and Holland contain four geographical miles each.

The Persian *leagues* are nearly the same with the Spanish; that is, each is equivalent to four Italian miles; which come nearly to what Herodotus mentions of the parasanga, an ancient measure among the Persians, containing thirty stadia; eight whereof, according to Strabo, make a mile.

The Persians mark their *leagues* by trees, as the ancient Romans did by stones, *lapides*; for which reason they are also called *agagi*, a Turkish word signifying a *tree*. In Japan, the *league* consists of 1800 fathoms. These are all distinguished by little hillocks, raised on purpose by the road-side. See the *leagues* of most countries reduced to the Roman foot, under MILE.

LEAGUE also denotes an alliance or confederacy between princes and states for their mutual aid, either in attacking some common enemy, or in defending themselves.

The word comes from *ligo*, which, in the corrupt Latin, was used for a *confederacy*: *Quo quis cum alio ligatur*.

There have been several holy *leagues* entered into by the Christians, against the Saracens and infidels; called also *crusades*, or CROISADES.

The LEAGUE, by way of eminence, denotes that famous one on foot in France, from the year 1576, to 1593. Its intent was to prevent the succession of Henry IV. who was of the Reformed religion, to the crown; and it ended with his abjuration of that faith.

The *leaguers* or confederates, were of three kinds: the *zealous leaguers* aimed at the utter destruction, not only of the Huguenots, but also of the ministry. The *Spanish leaguers* had principally in view the transferring the crown of France to the king of Spain, or the infanta his daughter. The *moderate leaguers* aimed only at the extirpation of Calvinism, without any alteration of the government.

LEAGUE *solemn*. See COVENANT.

LEAK, *in Sea-language*, is a chink or breach in the decks, sides, or bottom of a ship, through which the water comes in. A ship is said to *spring a leak* when she begins to *leak*, or let in the water.

The manner of stopping a *leak* is, to put into it a ling wrapt in oakum, and well tarred, or in a tarpaulin, &c.

clout, which keeps the water out; or nailing a piece of sheet-lead on the place.

Seamen sometimes stop a *leak* by thrusting a piece of salt beef into it. The sea-water, says Mr Boyle, being fresher than the brine imbibed by the beef, penetrates into its body, and causes it to swell so, as to bear strongly against the edges of the broken plank, and thereby stops the influx of the water. Works Abr. vol. i. p. 147.

A ready way to find a *leak* in a ship, is to apply the narrow end of a speaking-trumpet to the ear, and the other to the side of the ship where the *leak* is supposed to be; then the noise of the water issuing in at the *leak* will be heard distinctly, whereby it may be discovered. See Philos. Trans. N° 201.

LEAKAGE, the state of a vessel that *leaks*; that is, lets water, or other liquid ooze, in or out.

LEAKAGE also denotes an allowance of twelve per cent. to merchants importing wine, out of the customs thereof; and of two barrels in twenty-two, and three in twenty-three, to brewers, *&c.* out of the excise. 12 C. II. c. 24.

LEAO, in *Natural History*, a mineral substance approaching to the nature of the *lapis* LAZULI, found in the East Indies, and of great use in the Chinese porcelain manufacture, being the finest blue they are possessed of. This stone is found in the strata of pit-coal, or in those of a yellowish or reddish earth in the neighbourhood of the veins of coal. There are often found pieces of it lying on the surface of the ground, and these are a sure indication, that more will be found on digging. It is generally found in oblong pieces of the size of a finger, not round, but flat. Some of this is very fine, and some coarse, and of a bad colour. The latter is very common, but the fine sort is scarce, and greatly valued. It is not easy to distinguish them at sight, but they are found by experiment, and the trying one piece is generally sufficient for judging of the whole mine; for all that is found in the same place is usually of the same sort.

Their manner of preparing it for use is this: they first wash it very clean, to separate it from the earth, or any other foulness it may have; they then lay it at the bottom of their baking furnaces; and when it has been thus calcined for three or four hours, it is taken out and powdered very fine in large mortars of porcelain with pestles of stone faced with iron. When the powder is perfectly fine, they pour in some boiling water, and grind that with the rest, and when it is thoroughly incorporated, they add more, and finally pour it off, after some time settling. The remainder at the bottom of the mortar, which is the coarser part, they grind again with more water, and so on, till they have made the whole fine, excepting a little dirt or grit. When this is done, all the liquors are mixed together, and well stirred. They are suffered to stand two or three minutes after this, and then poured off, with the powder remaining in them. This is suffered to subside gradually, and is the fine blue they use in their best works, our common smalt serving for the blue of all the common low-priced China-ware. Observat. sur les Coutumes de l'Asie, p. 326.

It is plain that this stone is a sort of *lapis lunulæ*; and the ultramarine blue, used by our painters, is made in a manner not wholly unlike this. It is much to be wished, that England were well searched for such a stone as this is, since our mines in Derbyshire afford many blue substances, which have not been sufficiently considered; and if it should be found that either this, or any other European nation, produces it, it will be a fine discovery, as we should not only have the means of giving a fine colour to our own manufactures of this kind, but we might trade with it in China to a vast advantage. If England does not possess it, it is very probable that Germany does, the mines there affording an almost inexhaustible store of coloured stones; and this being certainly no other than the flinty matter of some crystalline nodule, accidentally tinged with some particles of copper. See LAZULI *lapis*.

LEAP, in *Music*, is when the song does not proceed by conjoint degrees. For instance, when there is an interval of a third, fourth, fifth, *&c.* between two notes, the Italians call it a *leap*, *salto*.

It is to be observed, that there are two kinds of *leaps*, regular and irregular, called by the Italians, *salti regolari & irregolari*.

The *regular leaps* are those of a third major or minor, whether natural or accidental, fourth, fifth, sixth minor, and octave, and these either ascending or descending.

Irregular leaps are the tritone, sixth major, seventh major, the ninth, tenth, and in general all beyond the compass of an octave; at least, in vocal music.

Besides these there are others which may be used, but with discretion; such as the diminished fourth, the false fifth, and flat seventh. The difference between the regular and irregular *leaps* is, that the former are performed by the voice, without any great difficulty or effort; whereas the latter require more attention and pains to execute.

LEAP, in *Fishing*, is used for a net, engine, or weel, made of twigs to catch fish in. Stat. 4 and 5 Will. and Mary, cap. 23.

LEAP, in the *Manege*, an air of a STEP and a *leap*.

LEAP-YEAR, the same with BISSEXTILE.

It is thus called, because, in the common year, any fixed day of the month changes successively one day of the week; but in the *leap-year*, it skips or *leaps* over one day.

The common year hath three hundred and sixty-five days in it, but the *leap-year* three hundred and sixty-six days; and in this case February hath twenty-nine days; which, in the common year, hath but twenty-eight.

To find the *leap-year*, the rule is,

Divide by 4, what's left shall be,
For leap-year, 0; *for* first, 1, 2, or 3.

For example; is the year 1780 a *leap-year*, or common-year?

4)1780(445.

There is 0 remainder, to that it is *leap-year*.

LEAPING-*horse*, in the *Manege*, is one that works in the high manege, or one that makes his *leaps* with order and obedience between two pillars upon a straight line, in volts, caprioles, balotades, or croupades. Use excludes a gallop *a terra a terra*, and corvets from the number of *leaps*; because the horse does not rise so very high in these. Each *leap* of the horse ought not to gain, or make above a foot and a half of ground forward.

LEASE, from the French *laisse, dimittere, to let*, in *Law*, a demise, or letting of lands, tenements, or hereditaments, unto another for life, term of years, or at will, for a rent reserved.

A *lease* is either written, called an *indenture, deed-poll*, or *lease* in writing; or by word of mouth called *lease separal*. See PAROL.

All estates, interests of freehold, or terms for years in lands, *&c.* not put in writing and signed by the parties, shall have no greater effect than as estates at will; unless it be of *leases* not exceeding three years from the making; wherein the rent reserved shall be two thirds of the value of the things demised. Stat. 29 Car. II. cap. 3. *Leases* exceeding three years must be made in writing, and if the substance of a *lease* be put in writing, and signed by the parties, though it be not sealed, it shall have the effect of a *lease* for years, *&c.*

The party who lets a *lease*, is called the *lessor*; and the party to whom it is let the *lessee*.

LEASES *by statutes*. There are three kinds of persons, who may make *leases* for three lives or twenty-one years, and not exceeding this term, by statutes, that could not do so heretofore, viz. tenants in tail, binding their issue in tail, but not in remainder or reverſion; husband and wife, of the wife's land; and persons seized of an estate in fee-simple in right of the church, except parsons and vicars. By the stat. 32 Hen. VIII. called the enabling statute.

But this statute specifies several requisites in order to render the *leases* binding: they must be by indenture, and not by deed poll, or by any poll. They must commence from the day of making, and not at any greater distance of time: the old lease, if there be any, must be first absolutely surrendered, or be within a year of expiring: the *leases* must be of corporeal hereditaments, and not of such things as lie merely in grant; for no rent can be reserved out of these by the common law, as the lessor cannot resort to them to distrain: though now by 5 Geo. III. c. 17. a *lease* of tithes or other incorporeal hereditaments, alone, may be granted by any bishop or ecclesiastical or eleemosynary corporation, and the successor shall be intitled to recover the rent by an action of debt, which, in case of a freehold *lease*, he could not have brought at the common law. The *lease* must also be of lands and tenements commonly letten for twenty years past: and the customary rent for that term reserved: and *leases* must not be made without impeachment of waste.

By 1 Eliz. c. 19. called the diſabling or reſtraining ſtatute, it is enacted, that all grants by archbishops and bishops, other than for the term of twenty-one years, or three lives from the time of making, or without reserving the usual rent, shall be void: but this statute did not extend to grants made by any bishop to the crown; however these as well as those made to any subject, were comprehended in the prohibition of the statute 1 Jac. I. c. 3. The restrictions of this statute were extended by 13 Eliz. c. 10. explained and enforced by 14 Eliz. c. 11. and 14. 18 Eliz. c. 11. and 43 Eliz. c. 29. to certain other inferior corporations, both sole and aggregate. From all these it is collected, that all colleges, cathedrals and other ecclesiastical or eleemosynary corporations, and all parsons and vicars are restrained from making any *leases* of any kind, of their land, unless under the following regu-

lations: 1. They muſt not exceed twenty-one years or three lives from the making. 2. The accuſtomed rent, or more, muſt be yearly reſerved upon them. 3. Houſes in corporations or market-towns may be lett for forty years; provided they be not the manſion-houſes of the ſeſſors, nor have above ten acres of ground belonging to them, and provided the leſſee be bound to keep them in repair; and they may alſo be aliened in fee-ſimple for lands of equal value in recompence. 4. Where there is an old *leaſe* in being, no concurrent *leaſe* ſhall be made, unleſs where the old one will expire within three years. 5. No *leaſe* by the equity of the ſtatute ſhall be made without impeachment of waſte. 6. All bonds and covenants tending to fruſtrate the proviſions of the ſtatutes 13 and 18 Eliz. ſhall be void. There is another reſtriction with regard to college *leaſes*, by ſtat. 18 Eliz. c. 6. which directs, that one third of the old rent, then paid, ſhould for the future be reſerved in wheat or malt, reſerving a quarter of wheat for each 6 *s.* 8 *d.* or a quarter of malt for every 5 *s.* or that the leſſees ſhould pay for the ſame according to the price that wheat and malt ſhould be ſold for, on the market next adjoining to the reſpective colleges, in the market-day before the rent becomes due. This money ariſing from corn rents is now, *communibus annis*, almoſt double to the rents reſerved in money. The *leaſes* of beneficed clergymen are farther reſtrained, in caſe of their non-reſidence, by ſtatutes 13 Eliz. c. 20. 14 Eliz. c. 11. and 18 Eliz. c. 11. which direct, that, if any beneficed clergyman be abſent from his cure above fourſcore days in any one year, he ſhall not only forfeit one year's profit of his benefice to be diſtributed among the poor of the pariſh; but all *leaſes* made by him of the profits of ſuch benefice, and all covenants and agreements of like nature, ſhall ceaſe and be void; except in the caſe of licenſed pluraliſts, who are allowed to demiſe the living, on which they are non-reſident, to their curates only, provided ſuch curates do not abſent themſelves above forty days in any one year. Blackſt. Com. vol. ii. p. 321, *&c.*

An ASSIGNMENT differs from a *leaſe* only in this: that by a *leaſe* one grants an intereſt leſs than his own, *reſerving* to himſelf a reverſion; in aſſignments he parts with the whole property, and the aſſignee ſtands to all intents and purpoſes in the place of the aſſignor.

LEASES *of the king*. *Leaſes* made by the king, of part of the duchy of Cornwall, are to be for three lives, or thirty-one years; and not to be made diſpuniſhable of waſte, whereon the ancient rent is to be reſerved; and eſtates in reverſion, with thoſe in poſſeſſion, are not to exceed three lives, *&c.* 13 Car. II. c. 4.

LEASE *and Releaſe*, is a conveyance of right or intereſt in lands or tenements, to another that hath the poſſeſſion thereof. Though the deed of feoffment was the uſual conveyance at common law; yet ſince the ſtat. of 27 Hen. VIII. of uſes, the conveyance by *leaſe and releaſe* has taken place of it, and is become a very common aſſurance to paſs lands and tenements; for it amounts to a feoffment, the uſe drawing after it the poſſeſſion without actual entry, *&c.* and ſupplying the place of livery and ſeiſin, required in that deed: in the making of it, a *leaſe*, or bargain and ſale for a year, or ſuch like term, is firſt prepared and executed, to the intent that by virtue thereof the leſſee may be in actual poſſeſſion of the lands intended to be conveyed by the *releaſe*, and thereby and by force of the ſtatute 27 Hen. VIII. c. 10. for transferring of uſes into poſſeſſion, be enabled to take and accept a grant of the reverſion and inheritance of the ſaid lands, *&c.* to the uſe of himſelf and his heirs for ever. See RELEASE.

LEASH, or LEASHE, among *Sportſmen*, denotes three creatures of any kind; but chiefly greyhounds, foxes, bucks, and hares.

We ſay a *leaſh* of greyhounds, a couple and a half of hounds.

LEAT, is uſed for a trench to convey water to or from a mill. It is mentioned in the ſtatute 7 Jac. I. cap. 19.

LEATHER, in *Commerce*, the ſkins of ſeveral ſorts of beaſts dreſſed and prepared for the uſe of various manufacturers, whoſe buſineſs it is to make them up, according to their different employments. The butcher and others, who flay them off the carcaſes diſpoſe of them raw or ſalted to the tanner and tawyer; they to the ſhamoy, morocco, and other kind of *leather*-dreſſers, who prepare them according to their reſpective arts, in order to vent them among the curriers and *leather*-cutters, glovers, harneſs-makers, coach-makers, ſaddlers, breeches-makers, pale-*leather*-makers, chair-makers, ſhoe-makers, bookbinders, and all in any way concerned in the article of *leather*.

Leather has divers names according to the ſtate wherein it is, and according to the different kinds of ſkins whereof it is prepared, and its peculiar qualities when ſo prepared.

1. The ſkin is raw as it comes off the animal. 2. Some are ſalted with ſea-ſalt and alum, or with natron, which is a ſpecies of ſalt-petre, or white ſalt-wort, to prevent corruption in keeping, or ſending to diſtant tanneries during hot ſeaſons.

Skins dried with the hair on, are commonly thoſe of oxen and cows, or buffaloes, either tame or wild. Moſt of thoſe in France come from foreign countries. The places which furniſh the largeſt quantity, are Peru, the iſle of St. Domingo, Barbary, Cape Verd iſles, the river Senegal in Africa, Muſcovy, Ireland, the iſland of Cuba. Thoſe of this latter place are the moſt eſteemed; they are called Havanna ſkins, from the name of the capital city of that iſland, whither they are carried in order to be ſent to Spain, and from thence into other parts of Europe. After theſe ſkins are ſtript of their hair, they are ſold to the tanners. See CURRYING, TANNING, and SKINS.

The three principal aſſortments of *leather* are tanned or tawed, and oil and alum *leather*, all which are dreſſed in ſome yards.

The art of dreſſing *leather* in oil conſiſts in firſt ſoaking the ſkins; then throwing them into the lime-pit; and when they are taken hence, pulling them and delivering them to the freizer: they are then ſtruck with the oil and ſent to the mill; when they are milled ſufficiently, they are thrown into the ditch to be ſcoured, and by ſome ſcudded, and afterwards hung upon the hooks to dry. When they have been weighed and marked by the proper officers, in order to fix the exciſe duty, they are fit for ſale. The ſorts of ſkins dreſſed in oil are thoſe of deer, ſheep, and lambs, and ſome few of goat, and the oil uſed for this purpoſe is Newfoundland or cod's liver oil. The alum *leather*-dreſſers art conſiſts in properly ſoaking, liming, wringing, (an operation ſometimes omitted) and ſtriking them in a liquor compoſed of water, ſalt, and alum, and then drying them properly. The ſort of ſkins dreſſed in alum are thoſe of ſheep and lambs, and a large quantity of kid. Poſtleth. Dict. Com. art. *Leather*.

There are ſeveral ſtatutes relating to *leather*; the 27 Hen. VIII. c. 14. directs packers to be appointed for *leather* to be tranſported: but the 18 Eliz. c. 9. prohibits the ſhipping of *leather* on penalty of forfeiture, *&c.* Though by 20 Car. c. 5 tranſportation of *leather* is allowed to Scotland, Ireland, or any foreign countries, paying a cuſtom or duty; which ſtatute is confirmed by divers ſubſequent acts.

On exportation of hides or ſkins, tanned, tawed, or dreſſed and marked, and of boots, ſhoes, gloves, and other manufactures made of *leather*, chargeable for the duty by weight, a drawback ſhall be allowed of two thirds of the duty. 9 Ann. c. 11. 12 Ann. ſtat. 2. c. 9. Except that for tanned *leather* manufactured into boots, ſhoes, gloves and other wares, a drawback of 14*d.* for a pound weight ſhall be allowed inſtead of the ſaid two-thirds of the duty. 12 Ann. ſtat. 2. c. 9. And a drawback of 1*d.* for a pound weight of ſeal ſkins tanned or tawed ſhall be allowed in lieu of any other draw-back. 9 Geo. III. c. 39.

No perſon ſhall ingroſs *leather* to ſell again, under the penalty of forfeiture. None but tanners are to buy any rough hides of *leather*, or calves ſkin in the hair, on pain of forfeiture; and no perſon ſhall foreſtall hides, under the penalty of 6*s.* 8*d.* a hide. *Leather* not ſufficiently tanned is to be forfeited. In London, the lord mayor and aldermen are to appoint and ſwear ſearchers and ſealers of *leather*, out of the company of cordwainers, *&c.* And alſo triers of the ſufficiency of *leather*; and the ſame is to be done by mayors, *&c.* in other towns and corporations; and ſearchers allowing inſufficient *leather*, incur a forfeiture of 40*s.* Shoemakers making ſhoes or boots of inſufficient *leather* are liable to forfeit for every pair 30. 4*d.* and the value thereof. 1 Jac. I. c. 22. Red tanned *leather* is be brought into open *leather* markets, and ſearched and ſealed before it be expoſed to ſale, and on ſale is to be regiſtered, or ſhall be forfeited; and contracts for ſale otherwiſe to be void, 13 and 14 Car. II. c. 7. Hides of *leather* are adjudged the ware and manufacture of the currier, and ſubject to ſearch, *&c.* All perſons dealing in *leather* may buy tanned *leather* ſearched in open market; and any perſon may buy or ſell *leather*, hides, or ſkins, by weight. 8 W. & M. c. 33. Duties are granted on *leather*, and entries to be made of tan-yards under the penalty of 50*l.* And tanners and *leather*-dreſſers uſing any private tan-yards or concealing ſkins, *&c.* ſhall forfeit 20 *l.* leviable by juſtices of the peace, by diſtreſs, *&c.* 9 Ann. c. 11. 10 Ann. c. 26. See 5 Geo. I. c. 2. and 9 Geo. I. c. 27. Vide TANNER. Foreign manufactured gloves imported ſhall be forfeited, and may be ſearched for and ſeized by any officer of the cuſtoms or exciſe; and every perſon importing or ſelling the ſame, ſhall alſo forfeit 200*l.* with double value. 9 Geo. III. c. 19.

LEATHER, *blacking for*. See BLACKING.

LEATHER, *buff*. See BUFF.

LEATHER, *fossil, ollaria montana*, is a foliated AMIANTHUS, consisting of soft fibres interwoven together and frequently containing sparry crystals inclosed in it.

LEATHER, *gilt*. See *Japanner's* GILDING, and LACQUER.

LEATHER *mills*. See MILL.

LEATHER *money*. See MONEY.

LEATHER-*mouthed*, in *Ichthyography*, a term used as the English for MALACOSTOMOUS, the distinctive epithet of such fishes as have thick lips and no teeth in their jaws; as the carp, tench, bream, roach, &c.

LEATHER-*sellers, company of*. See COMPANY.

LEATHER, *shamoy or shammy*. See SHAMMY.

LEATHER, *Turkey, method of preparing*, &c. See DYING *of Leather*.

LEAVE *and take*. See TAKE.

LEAVEN, any thing that will make a body swell, and ferment.

The word is formed of the French *levain*, which signifies the same, of the verb *lever*, or Latin *levare, to raise*.

Beer, ale, wine, and cyder, only work by means of the *leaven* in them. Sour paste, barm, rennet, &c. are *leavens* used in baking bread, brewing beer, making cheese, &c.

LEAVER. See LEVER.

LEBERIS, in some *Medical Writers*, a word used to express the exuvie of serpents, or the skins which snakes cast off every year; these are by some greatly recommended for taking off freckles and sun-burns from the face.

LEBNI, in the *Materia Medica of the Ancients*, a name given by some to storax. Avicenna has treated of this drug in three separate chapters. The Greeks were very nice in distinguishing the several kinds of storax, and the Arabians seem to have followed their example; nay, they have even borrowed some of the terms, by which they called the particular sorts. The soft, or liquid storax of the Greeks, seems to have been very common among these people, and they have called it *mel lebni*, the honey of storax. This was a common word with them to express any thing soft.

LECANOMANTIA, ΛΕΚΑΝΟΜΑΝΤΕΙΑ, in *Antiquity*, a kind of divination performed in a basin with wedges of gold or silver. See HYDROMANCY.

LECCIA, in *Ichthyology*, a name given by several to a large fish caught in the Mediterranean, and known among the generality of writers by the name of AMIA; though by Aldrovand, and some others, called *glaucus*. See LERCHIA.

LECH, in *Metallurgy*, a term used by the miners to express the gold ore which has been powdered and washed, and afterwards run with the assistance of lime-stone. The *lech* is afterwards burnt in a fire of charcoal, in order to render it fit for the separation of the metal, by means of lead, which absorbing and vitrifying the extraneous matter, renders the gold pure.

LECHEA, in *Botany*, a genus of the *triandria trigynia* class, with a three-leaved calyx, three linear petals, and a triple-celled three-valved capsule, including a single seed.

LECHIA, in *Ichthyology*, a name given by Paulus Jovius, and others, to the fish called by others *amia* and *glaucus*, and by the ancient Greeks *amia* and *thynnus*. It is properly a species of the scomber, and is distinguished by Artedi by the name of the *scomber* with two fins on the back, and with the last bone, or ray of the hinder fin, very long. The Italians call it *lecchia*, whence Jovius's name.

LECITHOS, a word used by the old medical writers, and plainly signifying a sort of pulse; but authors have variously understood it; some applying it to the decorticated seed of the lentil; others to the meal of the same pulse; and others to the fruit of a peculiar species of *orobus*, or wild vetch.

LECTICA, among the Romans, a litter, or vehicle, in which people were carried. The *sella* differed from the *lectica*, as being higher, and because people always sat in it; on which account the *sella*, from the time it was first brought into use, was esteemed the more honourable carriage of the two. See LITTER.

The *lectica* was also used as a bier for carrying out the dead, who were dressed in habits suitable to their quality and sex. Pitiſc. in voc. See BURYING.

LECTICARII, among the Romans, servants who carried the LECTICA.

LECTICARIUS was also an officer in the Greek church, whose business it was to bear off the bodies of those who died, and to bury them. These were otherwise denominated *decani* and *copiatæ*.

LECTIO, *reading*. Considered in a medicinal view, it is said by Celsus, lib. i. cap. 4. to be bad, especially after supper, for those whose heads are weak; and in lib. ii. cap. 8. he recommends reading with an audible voice, for such as have weak stomachs. It is also directed by Paulus Ægineta as an exercise, lib. i. cap. 19.

LECTISTERNIUM, a religious ceremony among the ancient Romans; being a festival prepared, and solemnly served up, in a temple, at a time of public calamity and danger.

And because, according to the customs of those times, they placed beds around the tables, and set the statues of the gods on those beds, in the same manner as men sat at meals, they called the solemnity *lectisternium*, from *lectus*, *bed*, and *sternere*, of *sterno*, *to spread, prepare*.

In this ceremony the Sibylline decemvirs presided; till the year of Rome 558, and afterwards the Epulones. See EPULO.

Casaubon has observed, from a passage in the scholiast of Pindar, that the Greeks had also a sort of *lectisternium* in use.

Livy observes, that the first *lectisternium* seen in Rome, was that which held for eight days successively, in honour of Apollo, Latona, Diana, Hercules, Mercury, and Neptune; on occasion of a contagious disease which killed almost all their cattle, in the year of Rome 354; though Valerius Maximus mentions one before that.

LECTORES, among the Romans, servants in great men's houses, who were employed in reading while their masters were at supper. They were called by the Greeks ΑΝΑΓΝΩΣΤΑΙ.

LECTURERS, in England, are an order of preachers in parish-churches, distinct from the rector, vicar, and curate. They are chosen by the vestry, or chief inhabitants of the parish, supported by voluntary subscriptions and legacies, and are usually the afternoon preachers in the Sunday service. The term is also more generally applied to those who preach on Sunday, or on any stated day of the week, in churches, or other places of public worship. By 13 & 14 Car. II. cap. 4. *lecturers* in churches, unlicensed, and not conforming to the liturgy, shall be disabled, and shall also suffer three months imprisonment in the common gaol; and two justices, or the mayor in a town corporate, shall, upon certificate from the ordinary, commit them accordingly. Where there are lectures founded by the donations of pious persons, the *lecturers* are appointed by the founders, without any interposition or consent of rectors of churches, &c. though with the leave and approbation of the bishop; such as that of lady Moyer's at St. Paul's. But the *lecturer* is not entitled to the pulpit, without the consent of the rector or vicar, who is possessed of the freehold of the church.

LECTURES. See BOYLE's *Lectures*.

LECTURES *of divinity*, &c. in the universities. See REGIUS *professors*.

LECTUS *igneus*, among the Romans, a kind of instrument of torture first invented by Decius. The bottom of it was set with serrated teeth or spikes, and strewed with fire; while melted tallow was poured from above on the unhappy tortured person.

LECYTHIS, in *Botany*, a genus of the *polyandria monogynia* class: the calyx is composed of six leaves; the corolla has six petals; the nectarium is ligulated and staminiferous; and the pericarpium, whose circumference is cut, is polyspermous.

LEDGER. See BOOK.

LEDGERS, among *Builders*. See PUTLOCK.

LEDGES, in a *Ship*, small pieces of timber lying athwart ships, from the waste-trees to the roof-trees, which serve to bear up the nettings, or the gratings over the half-deck. See GUTTER-*ledge*.

LEDUM, in *Botany*. See *Wild* ROSEMARY.

LEE, a term variously used at sea; though its general use be to signify the part towards, or opposite to the wind. This expression is chiefly used when the wind crosses the line of a ship's course, so that all on one side of her is called *to-windward*, and all on the opposite side, *to-leeward*. Hence,

LEE-*shore* is that on which the wind blows; so that to be under the *lee* of the shore, is to be close under the weather-shore, or under wind; or at a short distance from the shore which lies to windward.

A LEE *the helm*. See A-LEE.

LEE, *hard a*. See HARD.

LEE-*board, take care of the*, is a word of command to the man at the helm, to take care that the ship do not go to the lee-ward of her course.

To LEE-*ward*, denotes towards that part of the horizon which lies under the *lee*, or whither the wind bloweth.

LEE-*ward ship*, is one that is not fast by the wind, or which doth not sail so near the wind, nor make so good way as she should: or which is much to *leeward* of her course, when sailing close-hauled.

LEE, *to lay a ship by the*, or *to come up by the* LEE, is to bring

bring her ſo, that all her ſails may lie flat againſt her maſts and ſhrouds, and that the wind may come right upon her broadſide.

LEE-*ſangs*, are ropes reeved into the cringles of a yacht's or hoy's ſails.

LEE-*larches*, ſignify the ſudden and violent rolls which a ſhip often takes to the *leeward* in a high ſea, particularly when a large wave ſtrikes her on the weather-ſide.

LEE-*ſide*, denotes all that part of a ſhip or boat, which lies between the maſt, and the ſide fartheſt from the direction of the wind; or that half of a ſhip which is preſſed down towards the water by the effort of the ſails, as ſeparated from the other half by a line drawn through the middle of her length; that part of the ſhip, which lies to the windward of this line, is accordingly called the weather-ſide. Thus, if a ſhip ſails ſouthward, with the wind at eaſt, then is her ſtarboard, or right ſide, the *lee-ſide*; and the larboard, or left, the weather-ſide.

LEE-*way*, or LEE-*ward-way of a ſhip*, is the angle made by the line on which the ſhip ſhould run according to her courſe, or the point of the compaſs ſteered upon, and the real line of the ſhip's way, occaſioned by contrary winds, and a rough ſea.

All ſhips are apt to make ſome *lee-way*; ſo that in caſting up the log-board, ſomething muſt be allowed for *lee-way*. But the *lee-way* made by different ſhips, under the ſame circumſtances of wind and ſails, will be different; and even the ſame ſhip, with different lading, and having more or leſs ſail abroad, will make more or leſs *lee-way*. The ordinary rules of allowing for it are theſe: they were given by Mr. John Buckler to the late Mr. William Jones, who firſt publiſhed them about the year 1702.

1. When a ſhip is cloſe-hauled, has all her ſails ſet, the water ſmooth, and a moderate gale of wind, ſhe is then ſuppoſed to make little or no *lee-way*. 2. Allow one point, when it blows ſo freſh, that the ſmall ſails are taken in. 3. Allow two points, when the top-ſail muſt be cloſe reefed. 4. Allow two points and a half, when one top-ſail muſt be handed. 5. Allow three points and a half, when both top-ſails are to be taken in. 6. Allow four points, when the fore-courſe is handed. 7. Allow five points, when trying under the main-ſail only. 8. Allow ſix points, when both main and fore-courſes are taken in. 9. Allow ſeven points, when the ſhip tries a-hull, or all ſails are handed. When the wind has blowed hard in either quarter, and ſhifts across the meridian into the next quarter, the *lee-way* will be leſſened. But in all theſe caſes, reſpect muſt be had to the roughneſs of the ſea with the trim of the ſhip; and hence the mariner will be able to correct his courſe.

LEEA, in *Botany*, a genus of the *monoecia pentandria* claſs. This genus has male and female flowers; the calyx and corolla of both are divided into five ſegments; the corolla has a cylindric nectharium; the fruit is a ſix-celled pericarpium, including a ſingle ſeed.

LEECH, *hirudo*, in *Zoology*, an oblong animal, deſtitute of feet, and of a black colour, with various ſpots and lines, and a mouth with three diſtinct openings.

This, in the Linnæan ſyſtem, is a genus of the inteſtine worms, comprehending nine different ſpecies. It moves by dilating the head and tail, and raiſing the body into an arched form.

The *leech* is a well known inſect, common in waters, and uſed to draw blood in medicine. The common ſtanding waters afford us two ſpecies of this inſect, a larger, called the *horſe-leech*, and a ſmaller, diſtinguiſhed from this not only in ſize, but by its whole ſurface, being covered with ſmall tubercles. The larger kind grows to five inches long, and is yellowiſh on the belly, and black upon the back; it is divided, in the manner of the earth-worm, into a number of annular joints, not leſs than an hundred, and is ſmaller toward the mouth than toward the tail. The ſmaller kind has a broad ſtreak of a greeniſh black running down its back, and on each ſide of that a reddiſh line, and beyond theſe there are other lines formed of large black ſpots; the belly is blackiſh, with a caſt of green. This is the kind that ſhould be uſed in medicine, and is eaſily diſtinguiſhed from the other. Mr. Ray obſerves, that there are ſometimes found great numbers of young *leeches* ſticking in cluſters to the belly of the old one.

The hiſtory of this animal, and the ſtructure of its parts, by means of which it becomes uſeful to us, in ſupplying very happily the place of the lancet, with every other particular circumſtance of its life and food, have been very accurately given by Mr. Morand, in the Memoirs of the Academy of Sciences, in the year 1739.

The more vulgarly known particulars of this animal are briefly mentioned by this gentleman; ſuch are the cutaneous annules of its outer coat, the beautiful arrangement of the ſeveral rays, the colours, the pyramids, and points, with which it is ornamented; the avidity with which this creature ſeizes the fleſh of animals; the manner of its applying its mouth; the vermicular motion obſerved within it while ſucking, which reſembles the common motion of deglutition; the time they have been known to live in the water without any viſible food; and the faculty they have, in common with many other animals, of moving when cut into ſeveral pieces: theſe the author ſuppoſes already ſufficiently known, and paſſes on to what is leſs ſo, the ſtructure of its inner parts.

The part of this animal, by which it pierces the ſkin of any creature to get at its blood, is generally called, ſimply, its *mouth*; but it really conſiſts of five different parts, which are confounded under that general name. Theſe are two regular lips, a cavity, which is properly the mouth, certain inſtruments to pierce with, others which ſerve it for ſucking, and finally a ſort of throat, or œſophagus, through which it ſwallows the blood. When the *leech* is in a ſtate of reſt, its upper lip forms a regular ſemicircle, and the lower a portion of a much larger circle.

When the creature lengthens its head to move, the ſemicircle of the upper lip becomes two oblique lines, the junction of which makes a ſaliant angle, which the creature applies to whatever it would fix itſelf to. That angle is marked by a regular black ſpot on the outer edge of the lip. The extreme ſoftneſs of the fibres of this part makes it very ſerviceable to the animal, in that it readily aſſumes any figure, according to the occaſion of ſeizing any thing ſolid, in order to move the reſt of its body; or on the fleſh of an animal, to give opportunity to the piercing inſtruments to exert their force and action.

Whether it be for either of theſe purpoſes, that the creature fixes its mouth, the two lips regularly fix, and make in this ſtate a ſort of acetabulum, like the hollow of the tail. This may be ſeen in their fixing on the ſides of a glaſs-veſſel in which they are kept, and the mouth, or aperture between the lips, is diſtinctly ſeen. This mouth is formed, like the lips, of ſuch extremely ſupple fibres, that it takes the figure of the part to which it is applied, and fixes perfectly cloſe to it. When the lips are fixed on the fleſh, in order to ſuck, this little mouth continues moveable under them, and ſearches over the compaſs of fleſh, incloſed in the larger circle of the lips, for the ſpot where it will be eaſieſt to draw much blood.

Within this mouth is placed the inſtrument for piercing the ſkin, which is more than the mere ſucker of the gnat, or the like kind of flies; ſince the quantity of blood to be ſucked by the *leech*, is much larger, and the aperture of the veſſel muſt therefore alſo be larger. The ſhape of this weapon may be diſcovered by examining the wound it leaves. This is compoſed of three cuts, making three rays, and uniting in a center, under equal angles. This ſtructure of the wound is moſt diſtinctly ſeen when the ſwelling is gone down, and the ſkin is clean; and this is uſually on the fourth day after the application. The three openings are then plainly ſeen not to be punctures, but abſolute wounds, or cuts, as if made by a fine lancet. In examining the creature, the organ, deſtined for making the wound, is found to be placed between the aperture of the lips and the bottom of the mouth; and on cutting up the animal, and drawing the finger carefully over this part of it, there is felt a roughneſs like that of a fine file, which evidently is owing to ſome rough ſubſtance, of the hardneſs of bone. This is, in reality, a number of fine and ſharp teeth; and when examined by a microſcope, they are found to be diſpoſed in three ſeries on three ribs, or, as they may be called, jaws; each of which is placed along the middle of a ſtrong muſcle of its own length; and theſe correſponding regularly to a triangular opening, which the creature has in its mouth. When that has ſeized on a proper part for the getting blood, and is fixed, theſe muſcles exert their action, and ſtrike in the teeth through the ſkin.

Theſe are the inſtruments which pierce the veſſel which is to afford the blood; and for the receiving it into the body of the animal, there is between theſe rows of teeth, or in the common center of the mouth, a ſmall aperture; and within this there is a little body to be diſcovered, which by its motion ſeems very plainly to be a tongue, and which probably acts as a piſton to take up the blood flowing from the triple wound, in the center of which it naturally ſtands, while the larger circle of the lips, &c. perform the office of the body of the pump, and the blood is eaſily, by this means, conveyed into the body of the animal. Finally, between the root of the tongue and the beginning of the ſtomach, there is a ſpace of two lines in length, in which it [illegible] cover two different arrangements of fibres, [illegible] are flat and plain, the others are circular, [illegible] dently have a power of widening or contracting [illegible] vity of the pump, and by that means facilitating [illegible] the

the plane ones contracting in length, to enlarge the capacity, and the circular ones determining the blood towards the ſtomach, by their power of contracting the hollow, when the blood is received. The blood from hence enters into a membranaceous ſort of ſack, which ſerves the animal for the ſtomach and guts, and occupies the greateſt part of the body of the creature. If the air is admitted into the body by the mouth, it may be ſeen to make its way down a longitudinal canal, and ſill, as it goes, a number of ſacks, or little bags, which are on each ſide. Theſe veſicles receive the blood, and becoming filled with it, ſwell out the body of the animal to a great ſize. It remains here many months, and nouriſhes the creature; and if any thing is excreted from it, it muſt be merely by an inſenſible perſpiration; ſince the creature has no anus, ſo far as can be yet diſcovered, nor any aperture which can ſupply the place of one.

Leeches are able to live in oil; and when removed out of this liquor into water again, they throw off a tender ſkin, or film, of the regular ſhape of their body, and reſembling the ſkin of an eel in miniature. Their living in oil ſeems a proof, that their organs of reſpiration are not placed on the outſide of their bodies, as they are in many ſmall animals, which therefore die on being only rubbed over with oil. But the *leech* ſeems to reſpire by the mouth; and this may be the more plainly diſcovered, if the water, in which it is kept, be gently heated; for then the animal being uneaſy, breathes hard, and very viſibly.

We have on the coaſt of Cornwall another inſect, much approaching to the nature of the *leech*. It is about ſix inches long, of a greyiſh colour, ſpotted with black, and is divided into about nineteen rings. It has a great number of a ſort of tubercles on the body, and is uſually found full of blood, or of a ſubſtance reſembling blood in colour. Ray's Hiſt. Inſect. p. 3.

If a *leech* be kept in an eight-ounce glaſs phial, about three-fourths filled with water, it will indicate the changes of the weather, in the manner of a weather-glaſs. Thus, if the weather continues ſerene and beautiful, the *leech* lies motionleſs at the bottom of the phial, rolled in a ſpiral form: if it rains either before or after noon, it is found at the top of its lodging, where it will remain until the weather be ſettled: if we are to have wind, the *leech* gallops about its limpid habitation with amazing ſwiftneſs, and ſeldom reſts until it begins to blow hard: if a remarkable ſtorm of thunder or rain is to ſucceed, for ſome days before it lodges almoſt continually without the water, and diſcovers great uneaſineſs, in violent throws and convulſive like motions. In froſt, as in clear ſummer weather, it lies conſtantly at the bottom; and in ſnow, as in rainy weather, it dwells at the very mouth of the phial.

The phial ſhould be covered at the mouth with a piece of linen rag, and the water ſhould be changed once a week in the ſummer, and once a fortnight in the winter. Gent. Mag. vol. xxiii. p. 28.

LEECH, *ſea*. See HIRUDELLA *marina*.

LEECHES, *bleeding with*. The method of bleeding by theſe animals was very early introduced into the practice of phyſic. *Leeches* ſhould always be choſen from clear and running waters; for thoſe from ſtagnant ones, and dirty ponds, ſeem to have ſomething malignant in their bite. The ſurgeons uſually chooſe ſuch as have ſlender heads, green lines on their backs, and bellies of a reddiſh yellow. But from whatever waters theſe creatures have been taken, the beſt method is to keep them many days in a glaſs of water, changing it often, that they may cleanſe themſelves.

Before the *leech* is applied to the ſkin, it ſhould be taken out of the water, and kept an hour in an empty cup, to drain itſelf, that it may thus be rendered thirſty and empty. They may be properly applied to the temples, or behind the ears, in diſorders of the head, and to the veins of the rectum in the blind piles. And applied to this part alſo, they often prove of great ſervice in hæmorrhages, ſpittings of blood, or bleeding by the noſe; eſpecially when theſe have been occaſioned by a ſtoppage of the uſual diſcharges that way; though where this is not the caſe, they do great ſervice merely by revulſion.

Before the *leech* is applied, the ſkin muſt be well rubbed, till it become hot and red, and then either hold the *leech* by the tail to the part, or let it crawl of itſelf out of the cup upon it. By this means they readily lay hold; but if they refuſe, the blood of a chicken or pigeon ſhould be rubbed on the part; and if that does not allure them, they muſt be laid aſide as uſeleſs, and others taken in their ſtead.

If much blood is required to be drawn, the tails of the *leeches* may be cut off as they are ſucking; by which means, the blood they have already ſucked will be diſcharged, as well as what they continue to take in; for they will not let go their hold, but continue ſucking as before.

If they do not let go after a ſufficient quantity of blood is drawn, they are not to be pulled off, for that often occaſions tumours and inflammations; but if a little ſalt be ſprinkled on the place, they quit their hold. The orifices ſhould be waſhed with warm wine or water, and they uſually heal readily of themſelves. Heiſter's Surgery, p. 312.

LEECH is alſo a name given by Boccone to a very particular water-animal, which he found ſticking to the ſides of the *xiphias*, or ſword-fiſh.

He calls it *hirudo, or ocus cauda utrinque pennata*, and obſerves, that it is ſlightly mentioned by Geſner, and by Johnſon, in their books of fiſhes. It is about four inches long; the belly is white and cartilaginous, and tranſparent; there is no regular head to be ſeen, but only a hollow ſnout, in the place of the head; this is covered with a very hard membrane, and differs extremely from the ſkin of the belly; this ſnout it thruſts up to the end into the body of the fiſh, and ſucks its blood with it; it has a tail ſhaped like a feather, and under it two ſlender filaments or fibres, longer than its whole body. By means of theſe, when it is not faſtened to the body of the fiſh, it clings to ſtones, or ſea-plants, to prevent its being carried away by the motion of the water; and when it is on the body of the fiſh, theſe ſerve it to hold much more faſtly with, than it otherwiſe could do. This creature miſerably afflicts the ſword-fiſh, but it is itſelf as much tormented by an animal that preys on its blood and juices. This is a ſort of louſe, which is always found upon it; it is of a browniſh colour, and is generally found faſtened toward the tail of the creature, ſticking as firmly as a limpet to a rock; it is nearly of the bigneſs of a pea, and when cruſhed a little, will thruſt out ſeveral ſlender filaments. This *leech* is not found, ſo far as has yet been obſerved, on any other fiſh but the ſword-fiſh; nor this louſe among other creatures, beſides this *leech*. Phil. Tranſ. N° 100.

LEECH, or LEETCH *of a ſail*, in a *Ship*, the outward edge or ſkirt of the ſail from the earing to the clew, or rather the middle of the ſail between theſe two.

The *leeches* of all ſails, whoſe tops and bottoms are parallel to the deck, and at right angles with the maſts, are denominated from the ſhip's ſide, and the ſail to which they belong, as the ſtarboard *leech* of the main-ſail, the *lee-leech* of the fore-top-ſail, &c. But the ſails which are fixed obliquely upon the maſts, have their *leeches* named from their ſituation with reſpect to the ſhip's length; as the *fore-leech* of the *mizen*, the *after-leech* of the jib, or fore-ſtay ſail, &c. Falconer.

LEECH, or LEETCH-*lines*, in a *Ship*, are certain ropes faſtened to the *leeches* of the main-ſail and fore-ſail, and communicating with blocks under the oppoſite ſides of the top, whence they paſs downwards to the deck, ſerving to truſs up thoſe ſails to the yard, as occaſion requires. See BRAILS.

LEECH-*rope*, is a name given to that part of the BOLT-*rope*, to which the border of a ſail is ſewed. In all ſails, whoſe oppoſite *leeches* are of the ſame length, it is terminated above by the EARING, and below by the CLUE. Falconer.

LEEK, *porrum*, in *Botany*. Linnæus joins this to the genus of ALLIUM. Its characters are theſe: the flower is bell-ſhaped, and hath ſix petals, collected into a ſpherical head, covered by a common roundiſh ſpathæ or ſheath, which withers; they have ſix ſtamina, three of them alternately broader than the others; and have forked ſummits in their middle; they have a ſhort, round, three-cornered germen, ſupporting a ſingle ſtyle, crowned by an acute ſtigma; the germen becomes a ſhort, broad capſule, with three lobes, having three cells filled with angular ſeeds.

We have two kinds of *leek* commonly cultivated in our gardens, the one called the common *leek*, and the other a broader leaved one, commonly called the London *leek*. There are ſome reaſons to ſuſpect that theſe are only varieties of the ſame ſpecies of plant, both ariſing from the ſame ſeeds.

The method of propagating theſe is by ſeeds, and they are commonly ſown along with onions; the onions growing up firſt; and after they are pulled up, the *leeks* have time enough to grow to their ſize. Miller.

Leeks are more uſed in the kitchen among ſoups and broths, than in medicine; they are warming and attenuating, good to cleanſe the lungs from tough phlegm, and to help ſhortneſs of breath, and ſtoppage of the ſtomach; they are likewiſe reckoned good againſt the bites of venomous creatures. The juice of them is uſed to diſſolve the gums in the *pilulæ fœtidæ*.

LEEK, *houſe*. See HOUSE-*leek*.

LEEK-*head*, in the *Manege*. See WART.

LEER, in *Glass-making*, a sort of third furnace, intended to anneal and cool, by proper degrees, the vessels when made. This properly comprehends two parts, the tower and *leer*. The tower is that part which lies directly above the melting-furnace, with a partition between them of a foot thick, in the midst whereof there is a round hole, placed exactly over the furnace, through which the flame and heat pass into the tower: on the floor of this tower the vessels are set to anneal. There are two openings, by which the vessels are put into this tower, and after standing there some time, they are put into iron pans, which by degrees are drawn out all along that part of this furnace, which is properly called the *leer*; which is five or six yards long, that the vessels may cool by degrees. This *leer* is continued to its tower, and arched all along, and is about four feet wide, and high within. The glasses are cool by that time they are come to the mouth of this, which enters into a room where the glasses are placed when taken out. Neri's Art of Glass, p. 243. See FURNACE and GLASS.

LEES, the grossest and thickest parts of wine, oil, and other liquors; or the sediment found at the bottom of the vessel.

The word comes from the French *lie*, and that either from *limus*, *mud*, or from *Lyæus*, one of the surnames of Bacchus; or, according to Du-Cange, from *lia*, a corrupt Latin word, signifying the same.

A kind of pot-ash, called *cinres clavellati*, is made with the *lees* of wine burnt, and prepared, used by dyers, &c. which ought to be remembered by people troubled with the stone, &c.

The vinegar-makers make a great trade of the *lees* of wine dried, and made into cakes, after having squeezed out the remains of the liquor in presses.

LEET, *leta*. See COURT-*leet*, and FRANK-*pledge*.

The business of the *leet* hath declined for many years, and is devolved upon the quarter-sessions. All freemen between the age of twelve and sixty, except peers, clergymen, and the king's tenants in ancient demesne, were bound to appear at this court.

LEG, *crus*. See LEGS.

LEGACY, *legatum*, in the *Civil Law*, a donation by testament; answering to what in common law is called a *demise*; and the person to whom it is given is styled the LEGATEE.

Legacy is usually defined some particular thing given by a last will and testament; because if a man thus dispose, or transfer his whole estate on another, it is called *hæreditas*; and he to whom it is given, is called *hæres*. Though, in common law, the distinction is this: that he to whom all a man's lands and hereditaments descend by right of blood, is *hæres natus*; the other, to whom it is bequeathed, is called *hæres factus*.

With regard to the payment of *legacies*, if a *legacy* when due be paid to the father of an infant, it is no good payment; and the executor may be obliged in equity to pay it again; and where any *legacy* is bequeathed to a femecovert, paying it to her alone is not sufficient, without her husband.

LEGACY, *contingent*. See CONTINGENT.

LEGACIES, *interest on*. See INTEREST.

LEGACY, *lapsed*, is where the legatee dies before the testator. See CONTINGENT.

LEGACY, in an *Ecclesiastical Sense*, was a soul-seat, a bequest to the church, or accustomed mortuary; which was to hold good, even though the testament itself were declared null and invalid.

LEGAL *column*, *economy*, *subrogation*, and *tutorage*. See the several substantives.

LEGALIS *homo*, in *Law*, a person who stands rectus in curia, not outlawed, nor excommunicated, nor infamous. And in this sense are those words so often used, *probi & legales homines*.

Hence all *legality* is taken for the condition of such a man.

LEGATE, a prelate, whom the pope sends as ambassador to any sovereign prince.

The term *legate* comes from *legatus*, which Varro derives from *legere*, *to choose*; and others from *legare*, *delegare*, *to send*, or *delegate*. Wicquefort.

There are three kinds of *legates*; viz. *legates à latere*, *legates de latere*, and *legates* by office, or *legati nati*.

Of these, the most considerable are the *legates à latere*; such are those whom the pope commissions to take his place in councils; who are thus called, because the pope never gives this office to any but his greatest favourites and confidants, who are always at his side, *à latere*; that is, to the cardinals.

A *legate à latere* may confer benefices without mandate, legitimate bastards to hold offices, and has a cross carried before him, as the ensign of his authority.

The *legates de latere* are those who, not being cardinals, are yet entrusted with an apostolical legation.

Legates by office, *legati nati*, are those who have not any particular legation given them; but who, by virtue of their dignity, and place in the church, become *legates*. Such are the archbishop of Rheims and Arles. But the authority of these *legates* is much inferior to that of the *legates à latere*. The power of a *legate* is sometimes also given without the title; some of the nuncios are invested with it.

LEGATE, *court of the*. See COURT.

LEGATE-*note*, in the *Italian Music*. Notes are said to be *legate*, when this ⌒, or this ⌣ mark is found over or under the heads of them. This is what we call *tying* them, and is done when they are properly but one note, but obliged to be separated into two, because part is found at the end of one bar, and the other part in the beginning of the following bar; or because the two halves of a note are in different parts of the measure. See SYNCOPE.

LEGATEE, or LEGATARY, in *Law*, the person to whom a LEGACY is left; which every person is capable of being, unless particularly disabled by the common law or statutes, as traitors, papists, and some others.

LEGATEE, *residuary*, in *Law*, is the person to whom the *residuum*, or what remains of an estate, after funeral charges, debts, and legacies, are paid, is left by will. See EXECUTOR.

LEGATINE *constitutions*. See CONSTITUTIONS.

LEGATIS *tenementis*. See TENEMENTIS.

LEGATO, in the *Italian Music*, signifies confined or constrained by certain rules for some design; thus they say, *canone legato*, &c.

LEGATORY, or LEGATARY, a term used in speaking of the government of the ancient Romans: Augustus divided the provinces of the empire into consular, *legatory*, and presidial.

LEGATORY *provinces* were those whereof the emperor himself was governor, but where he did not reside, but administered affairs by his lieutenant, or *legatus*.

LEGATORY, or LEGATARY, the same with *legatee* of a will. 27 Eliz. cap. 16. It is derived from the Latin *legatarius*.

LEGATUS, among the Romans, a military officer, who commanded as deputy of the chief general.

Of these there were divers kinds; viz. *legates* in the army under the imperator, or general, answering to our lieutenant-general; and *legatus* in the provinces, under the procontul, or governor.

When any considerable person among the Roman citizens had occasion to pass through any of the provinces, the senate gave him the title of *legatus*; that is, of envoy from the senate, to the end that he might be received with the greater respect; and that the cities and towns, through which he travelled, might defray his expences. This they called a *free legation*, *libera legatio*; because the person was not incumbered with any trust, and might lay it aside as soon as he pleased.

LEGEM, *ad communem*, *entry*, in *Law*, a writ of entry which lies where tenant for term of life, or for term of another's life, or by courtesy, &c. aliens and dies, when he in the reversion, shall have his writ against any one that is in possession of the land. New Nat. Brev. 461.

LEGEND, *legenda*, was originally a book used in the old Romish churches, containing the lessons that were to be read in divine service.

Hence also the lives of saints and martyrs came to be called *legends*; because the chapters were read out of them at matins, and in the refectories of the religious houses.

The first Greek *legend* which is known is that of Simon Metaphrastus of the tenth century, who writ the lives of saints adapted to every day of the year. The first Latin *legend* is

LEGEND, *golden*, or a collection of the lives of the saints, compiled by James de Varasc, better known by his Latin name of J. de Voragine, vicar-general of the Dominicans, and afterwards archbishop of Genoa, who died in 1298.

It was received into the church with great applause, which it maintained for two hundred years; but, in effect, it is so full of ridiculous and romantic accounts, that the Romanists themselves are now generally ashamed of it. The word *legend* itself is, on that account, come into disrepute.

LEGEND is also used by authors to signify the words or letters engraven about the margins, &c. of coins.

Thus, the *legend* of a French crown is, SIT NOMEN DOMINI BENEDICTVM; that of a moidore, IN HOC SIGNO VINCES; on those of the last emperors of Constantinople, we find IESVS CHRISTVS BASILEVS BASILEON, IHS XPS NIKA, IESVS CHRISTVS [illegible]

LEGEND is also applied to the inscription of medals, which serves to explain the figures or devices thereof.

In ſtrictneſs, the *legend* differs from the *inſcription*; this laſt properly ſignifying words placed on the reverſe of a medal, in lieu of figures.

It ſeems as if the ancients had intended their medals ſhould ſerve both as images, and as emblems: the one for the common people, and the other for perſons of taſte and parts; the images to repreſent the faces of princes; and emblems to repreſent their virtues, and great actions; ſo that the *legend* is to be looked on as the ſoul of the medal, and the figures as the body.

Every medal has properly two *legends*; that on the front, and that on the reverſe. The firſt generally ſerves only to diſtinguiſh the perſon by his name, titles, offices, &c. the latter is intended to expreſs his noble and virtuous ſentiments, his good deeds, and the advantages the public has reaped by him. This, however, does not hold univerſally; for ſometimes we find the titles ſhared between both ſides, and ſometimes alſo the *legend*.

In the medals of cities and provinces, as the head is uſually the genius of the place, or, at leaſt, ſome deity adored there, the *legend* is the name of the city, province, or deity, or of both together; and the reverſe is ſome ſymbol of the city, &c. frequently without a *legend*, ſometimes with that of one of its magiſtrates.

The ordinary ſubjects of *legends* are, the virtues of princes, the honours they have received, conſecrations, ſignal events, public monuments, deities, public vows, privileges, &c.

Legends, and inſcriptions of medals, are either in Latin, or Greek. The Greek character, conſiſting of majuſcule, or capital letters, appears uniform on all the medals; no change or alteration being found in confounting the ſeveral characters; though it is certain there was in the ordinary uſe and pronunciation. All we obſerve on medals is ſometimes a mixture of Greek and Latin letters. The character was preſerved in all its beauty, till the time of Gallienus.

From the time of Conſtantine, and for the ſpace of five hundred years, the Latin tongue was alone uſed in the *legends* of medals, even in thoſe ſtruck at Conſtantinople. Michael began the firſt, whoſe *legend* was in Greek; and from his time the language, as well as the characters, began to alter for the worſe. See MEDAL.

The Latin *legends* are all read from the left to the right: but the *legends* of ſome Greek medals are wrote the contrary way, from the right to the left. The letters of the circular *legends* are commonly placed with the bottoms inward; but ſometimes with the bottoms toward the edge.

LEGER-*line*, in *Muſic*, is uſed to ſignify a line added to the ſtaff of five lines, when the aſcending and deſcending notes run very high or very low. We often meet with ſeveral of theſe lines both above and below the ſtaff.

LEGGIARDO, or LEGGIARDAMENTE, in the *Italian Muſic*, is uſed to intimate, that the muſician is to ſing or play in a gay, briſk, and lively manner. See ALLEGRO.

LEGION, a kind of regiment, or body of forces, of a number whereof the Roman armies were chiefly compoſed.

The word comes from the Latin *legere*, to *chooſe*; becauſe, when the *legions* were raiſed, they made choice of ſuch of their youths as were the moſt proper to bear arms.

The number of ſoldiers and officers, whereof the *legion* conſiſted, was different at different times: but it is impoſſible to determine the preciſe time and manner of their alteration. In the time of Romulus, the inſtitutor of this corps, each legion contained three thouſand foot, and three hundred equites, or horſe: theſe were divided into three bodies, which make as many orders of battle: each body conſiſting of ten companies, or manipules, ranged at ſome diſtance from each other, though in the ſame front. Each body had two general officers to command it, called *tribunes*; and each manipule, two centurions.

Under the conſuls, the *legion* conſiſted of four thouſand, or four thouſand two hundred foot-ſoldiers, who made four bodies, commanded by a conſul, or one of his lieutenants; and each *legion* had its ſhare of cavalry, which was three hundred horſe.

About the year of Rome 412, it was compoſed of five thouſand foot; which was the number of a *legion* during Julius Cæſar's wars with the Gauls. Under Auguſtus, each *legion* conſiſted of ſix thouſand one hundred foot, and ſeven hundred and twenty-ſix horſe. After his death, they were reduced to five thouſand foot and ſix hundred horſe. Under Tiberius, the *legion* was raiſed again to ſix thouſand foot and ſix hundred horſe. In the time of Septimius Severus, the *legion* was compoſed of five thouſand men: under the following emperors, it was the ſame as it had been under Auguſtus.

In the time of Marius, thoſe four diviſions of the *legion* which had taken place under the conſuls, were united into one, and augmented; and cohorts were appointed from five to ſix hundred men, each under the command of a tribune. Each cohort conſiſted of three companies or manipules, each manipule of two centuries, and the *legion* was divided into ten cohorts, who made as many diſtinct battalions, diſpoſed in three lines; ſo that the *legion*, then, conſiſted of ſix thouſand men.

Iſidore tells us, that the *legion* conſiſted of ſix thouſand men, and was divided into ſixty centuries, thirty manipules, twelve cohorts, and two hundred troops. According to the French academy, the *legion* conſiſted of ſix thouſand foot, and ſeven hundred twenty-five horſe.

The *legion* conſiſted of four ſorts of ſoldiers, who differed in their age, arms, and names: they were called VELITES, HASTATI, PRINCIPES, and TRIARII. Till the deſtruction of Carthage, theſe were citizens of Rome, but after the Social War, the freedom of the city was granted to other towns in Italy, and legionary troops were raiſed which were called Roman, becauſe as they ſhared the privileges of Roman citizens, they were incorporated in the republic.

The *legions* were by far the moſt conſiderable part of the Roman army; their number in the time of Auguſtus, was thirty-three; they were compoſed wholly of Roman citizens. The allies formed a body of auxiliary forces.

The ſtandard borne by the *legions* was various: at firſt, a wolf, in honour of that which ſuckled Romulus; afterwards an hog; by reaſon, ſays Feſtus, war is only undertaken with a view to peace, which was concluded by ſacrificing an hog. Sometimes they bore the minotaur, to remind their general, that their deſigns were to be kept ſecret, and inacceſſible as the minotaur in the labyrinth. They alſo bore an horſe, a boar, *&c.* Pliny tells us, that Marius was the firſt who changed all theſe ſtandards into EAGLES.

The different *legions* were diſtinguiſhed according to the order in which they were raiſed into firſt, ſecond, and third, *&c.* by the names of the emperors who formed them, into *legio Auguſta*, *Claudia*, *Flavia*, *Trajana*, *&c.* by the provinces where they had ſerved, as *legio Parthica*, *Macedonica*, *&c.* and by ſome famous exploit or diſplay of valour.

LEGION, *ſquare*, *legio quadrata*, was a *legion* conſiſting of four thouſand men.

LEGIONUM, *domeſticus*. See DOMESTICUS.

LEGION, *thundering*. See THUNDERING.

LEGION, *Theban*, is a name given by ſome authors to a *legion* of Roman ſoldiers, who refuſing not to ſacrifice to idols, ſuffered martyrdom under the emperors Dioclefian and Maximilian, about the year of Chriſt 297. But the whole account of them ſeems to be fabulous.

LEGISLATOR, *lawgiver*; a perſon who frames the laws of a kingdom or ſtate founded by him.

The principal ancient *legiſlators* are—Moſes, *legiſlator* of the Hebrews; Mercurius Triſmegiſtus, and Boechyris, of the Egyptians; Italus, of the Œnotrians; Thelcus, Draco, and Solon, of the Athenians; Zoroaſter, of the Bactrians; Charondas, of the Cappadocians; and Charondas or Phaleas, of the Carthaginians; Andredamas, of the Chalcidians; Endoxus, of the Cnidians; Philo, of the Corinthians; Minos of the Cretans; Pythagoras, of the Crotoniates, and moſt of the cities of the Grecia Major; Parmenides, and Zeno, of Elea, in Lucania; Xamolxis, of the Getæ; Pherecus, of the Greeks; Bacchus of the Indians; Saturn of Italy; Macarius, of the Iſle of Leſbos; Zaleucus, of the Locrians; Nicodorus Athleta, of the city of Mutina; Hippodamia, of Miletus; Charondas, of Rheggio; Lycurgus, of the Lacedemonians; Archytas, of Tarentum; Philolaus, of the Thebans.

At Rome the people were in a great meaſure their own *legiſlators*; though Solon may be ſaid, in ſome ſenſe, to have been their *legiſlator*, as the decemviri, who were created for the making of laws, borrowed a great number from thoſe of Solon.

With us the legiſlative power is lodged in the king, lords, and commons aſſembled in PARLIAMENT.

LEGITIMATE *delivery*. See DELIVERY.

LEGITIMATE *tertian*. See FEVER.

LEGITIMATION, an act by which natural or illegitimate children are rendered legitimate. See BASTARD, *&c.*

By the French law, the father and mother, by marrying, render their children, begotten before marriage, legitimate; and this is called *legitimatio per ſubſequens matrimonium*.

The right of *legitimation* was a thing unknown to princes till the time of Conſtantine; but, ſince his time, has been exerciſed by moſt of them. The Greek emperors invented ſeveral kinds of *legitimation*.

Anaſtaſius put it in the power of the father to *legitimate* his natural children, by a bare adoption, provided he had no legitimate children. But Juſtin, by his conſtitu-

tion, and Juſtinian, by his Novel 74, aboliſhed this *legitimation*, as fearing the too eaſy acceſs to *legitimation* ſhould encourage concubinage.

In lieu of this, he eſtabliſhed a way of *legitimation* by the emperor's letters. This rendered baſtards capable of attaining to honours, and even of ſucceeding to inheritances, provided the perſons were *legitimated* with the conſent of their father and mother: which is agreeable to the canon law.

LEGNA, Λεγνα, among the *Ancients*, a name given to the borders of the *toga* and *pallium*, that were on each hand; the extremities above and below being called ORA.

LEGS, the lower extremes of the bodies of moſt animals, ſerving them for ſupport and motion. See ANIMAL, and EXTREME.

Some anatomiſts divide the foot of man into three parts, *viz.* the *thigh*, the *leg*, and the leſſer FOOT.

In the *leg* there are two conſiderable bones; the one called the *great ſuſſile*, or TIBIA; the other the *little ſocile*, or FIBULA.

In fractures of the two bones of the *tibia* and fibula, or either of them alone, the limb is to be extended, by aſſiſtants, both ways, while the ſurgeon replaces the bones, which done, the limb is to be rolled up with the proper bandage, and retained in the moſt proper poſture.

When both theſe bones are broken, they are ſeldom both broken juſt in the ſame place, but one a little higher than the other. If the *tibia* be broken alone, it is eaſily diſcovered by its lying ſo near the ſkin; but if the *fibula* alone, it is buried under ſo many muſcles that the fracture is not always ſo eaſily diſcovered, and the patient is ſo much leſs afflicted by it, as to be ſometimes able to walk.

If a fracture of the *tibia* be accompanied with an external wound, this muſt be firſt well cleanſed, and the ſplinters of the bone carefully removed, and then the broken bone, by the help of a proper extenſion, reduced to its proper place, the hæmorrhage ſtopped, and the whole bound up with the eighteen-headed bandage; but if any fragments of the bone ſtick out, ſo as to hinder its reduction, they muſt be firſt removed by a pair of ſharp forceps, or if neceſſary a fine ſaw. The limb, when ſet, is to be laid in a proper frame, or in a caſe of ſtraw, renewing the dreſſing and bandage daily till the wound be healed. Heiſter, p. 136.

LEGS, *ulcers of the*. Although no part of the body is free from inveterate and obſtinate ulcers, yet the *legs* are found to be much more ſubject to them than the reſt. The general cauſes of ulcers in the *legs* are the ſame with thoſe of ulcers in other parts, a bad habit of body, too great a thinneſs and acrimony in the juices, and obſtruction of the menſes in women; to theſe alſo may be added callofity of the lips of wounds, and caries of the bones within.

In perſons advanced in years, and naturally of a bad habit of body, it is moſt adviſeable not to attempt to heal theſe, ſince the effect of cure is often much worſe than the diſeaſe, and not unfrequently even death itſelf: for theſe ulcers are, in many caſes, rather to be looked on as a relief to nature than a diſorder, as they ſerve to drain off a vaſt quantity of noxious humours from the body. This, however, ſhould not be extended to young robuſt habits, though bad, becauſe theſe may be corrected in ſuch ſubjects, and the firſt cauſe of the ſtubbornneſs of the ulcers removed by abſtinence, or a regular way of living, or by opening iſſues, with the help of internal remedies; and the cauſe thus removed, the ulcer may be removed with perfect ſafety: and though in old perſons theſe ulcers are not to be healed, yet palliative methods may be taken with them, to the great comfort of the afflicted perſons, that pain, and other violent ſymptoms may be removed, and the ulcer kept from ſpreading, or new bad ſymptoms from coming on.

Abſtinence and a ſtrict regimen are the great objects, and gentle doſes of purging medicines are to be taken at times, and internal medicines, likely to do good in regard to the cauſe of the ulcer, may be alſo given: of this kind are eſſence of myrrh, balſam of Peru, and the like. Externally, care muſt be taken to keep the ulcer perfectly clean; twice a day it ought to be dreſſed, and every time wiped clean from the ſanies; it ſhould then be dreſſed either with dry lint, or with lint dipped in a decoction of walnut-leaves, or of birthwort, and over this a lead-plaſter, as that of the minium, or any of a like kind may be applied. Theſe ulcers treated in this eaſy manner will become very mild, of little trouble, and of great ſervice to the preſerving the life of the patient.

When inflammations and violent pains come on in theſe caſes, as they very frequently do from a blow, from cold, from dipping the *leg* in cold water, or from violent paſſions of the mind, or irregularity of diet, a linen compreſs muſt be applied in this caſe, dipped in Hungary-water, or ſpirit of wine with camphor, or with a mixture of equal parts of lime-water, and either of theſe liquors; theſe ſhould be applied warm; the patient ſhould be confined to his bed, and the limb carefully defended from the injuries of the external air, and ſmall liquors ſhould be frequently drank warm to promote gentle ſweating; when the inflammation runs very high, and threatens a gangrene, great care is to be taken, and the methods uſed in inflammations and gangrenes regularly applied, otherwiſe there is the greateſt danger that a ſphacelus and death will be the conſequence.

When the ulcers dry up of themſelves in old people, naufeas, horrors, and great weakneſs uſually ſucceed, which ſhew death at hand: in this caſe, the patient's ſtrength and ſpirits muſt be kept up as much as poſſible, and gentian and florentine iris-root muſt be applied in powder to the wound; and if theſe are of too little force, black hellebore-root, either in powder or formed into little balls; and laſtly, powder of cantharides, or ſmall pieces of the common bliſtering-plaſter. If theſe applications ſucceed, and produce a running of the ulcer again, the methods before directed muſt be again cautiouſly purſued; but if theſe fail of ſucceſs, there is little hope of life. Heiſter's Surgery, p. 253.

The *legs* and feet of the ſeveral animals, Mr. Derham obſerves, are exactly conformable to the poſture, make, nay, to the motion and exerciſes, of thoſe animals. In ſome they are made for ſtrength only, in others for agility and ſwiftneſs; in ſome for walking and running, in others for ſwimming, in others for digging, and in others for flying. In ſome, more lax and weak, for traverſing the plain land; in others, ſtiff and rigid, for ice and precipices. In ſome, ſhod with tough and hard hoofs, ſome whole, ſome cleft. In ſome the feet are compoſed of toes; ſome ſhort, for only going, others long, to ſupply the place of hands; ſome are armed with talons, to catch and tear their prey; and ſome with ſhort nails, to confirm their ſteps in running and walking.

In birds, the *legs* are curved, for their eaſy perching, rooſting, and reſt; as alſo to help them on the wing in taking their flight, and to be therein commodiouſly tucked up to the body, ſo as not to obſtruct their flight. In ſome they are long, for wading, *&c.*

LEGS *of flies*. Theſe furniſh us with ſeveral diſtinctions for this large claſs of inſects. All flies have indeed ſix *legs*, but though they are the ſame in number, they differ ſufficiently in many other reſpects. Some flies have very long *legs*, and others as remarkably ſhort ones.

The gnats and tipulæ ſeem mounted on ſtilts, and by that differ from other flies, whoſe form of body is the ſame; but what is yet more obſervable in regard to the *legs* of theſe inſects is, that though they are uſually all fixed to the corcelet, there are ſome ſpecies of flies which have the hinder pair faſtened to the rings of their body.

The *legs* of flies are often not only large or ſmall according to the ſize of the creature, but every portion of them comprized between two of the articulations, differs often from the other in length and thickneſs. What they all have in common is, that the foot, or bottom part of them, on which the creature reſts itſelf, is always provided with at leaſt two claws, or hooks, which terminate in points ſo extremely fine, that they are able to lay hold of what appears to us the moſt ſmooth and poliſhed bodies.

The blue fleſh-fly, and ſeveral other ſpecies, have alſo, as it were, two ſoles of feet; theſe are each of them nearly of a boat figure, and reſemble two ſmall balls; theſe touch at the part where they are connected to the foot, and leave between them an angular ſpace afterwards. Their external inferior ſurface is ſomewhat convex, and covered with very ſhort hairs very cloſely arranged; theſe hairs, like the points of the two claws, can find themſelves a paſſage into the pores of what appear to us the moſt poliſhed ſurfaces, and are of great uſe to the creatures, in their placing themſelves on vertical panes of glaſs.

Mr. Homberg has ſometimes found flies which could not walk upon glaſs in this poſition; and is of opinion, that there are ſuch, as by age had loſt the hairs from theſe balls on their feet. Thoſe alſo whoſe claws or hooks were become ſoft or blunt muſt find themſelves in the ſame ſituation: yet there are ſeveral ſpecies of flies which have not theſe balls; ſuch as the bee claſs, which yet are able to walk up our window glaſſes with great eaſe. Reaumur, Hiſt. Inſ. vol. iv. p. 259.

LEGS, in the *Manege*, the members that ſupport a horſe's body, and perform the motion when he goes. Of the four *legs*, the two before have ſeveral parts, each of which has a peculiar name: ſo that by the name of fore-*leg*, we commonly underſtand that part of the fore-quar-

ters that extends from the hough to the pastern-joint, and call it the *shank*; the part that corresponds to this in the hind-quarters is called the *instep*. But in common discourse we confound the fore and the hind-quarters; and without any distinction say the *four legs* of a horse. The French call a horse *droit sur les jambes*, i. e. straight membered, or straight upon his *legs*, when the fore-part of the pastern falls perpendicularly upon the *coronet*, and the shank and the pastern are in a straight line. See STRAIGHT and LONG-*jointed*.

The horseman's legs are likewise of singular concern in the manage, for the action of these given seasonably, and with a little judgment, constitutes one of the principal aids, which consists in approaching more or less with the *calf* of the *leg* to the horse's flank, and in bearing it more or less off as there is occasion. This aid a horseman ought to give very nicely, in order to animate a horse: and it is so much the finer, that it is hidden and private: for in stretching the hand he makes the horse dread the spur, and this spur has as much effect as the spur itself. See AID.

LEGS *of the mortises*, in a *Ship*, is used for those small ropes, which are put through the bolt-ropes of the main and fore-sail, in the leech of each. They are above a foot in length, and at either end are spliced into themselves: they have also a small eye, into which the *mortises* are fastened by two nitches, and the end is seized into the standing part of the *mortises*.

LEGS, *long*, in *Natural History*. See TIPULA.

LEGS *of a triangle*.—When one side of a triangle is taken as a base, the other two are called *legs*. See TRIANGLE.

LEGS, *arched*. See ARCHED.

LEGS, *compasses of three*. See COMPASSES.

LEGS, *hyperbolic*. See HYPERBOLIC.

LEGUME, among *Botanists*, a *pericarpium* of an oblong compressed figure, formed of two valves, joined by a visible suture, both on the upper and under part, and having the seeds affixed to the upper limbs of the two valves in an alternate order. See PERICARPIUM.

LEGUME or LEGUMEN, is applied, by botanists, to beans, peas, vetches, &c. otherwise called *pulse*.

Some will have them thus called, in regard they are gathered with the hand; by which they are distinguished from corn, &c. which are mowed or reaped: *segetes manu legitur & non secatur*.

Yet the ancient writers on husbandry consider corn, and even turneps, and all grains, and roots for family-use, as *legumina*.

LEGUMINOUS, an appellation given to those plants which yield legumes, or pulse.

Of this kind are most plants which grow in pods, as beans, peas, &c.

Ray ranks all plants as *leguminous*, which have a papilionaceous or butterfly-like flower.

LEGUMINOUS *flowers*. See FLOWER.

LEIBNITZIAN *philosophy*, or the philosophy of Leibnitz, is a system of philosophy formed and published by its author in the last century, partly in emendation of the CARTESIAN and partly in opposition to the NEWTONIAN. The very ingenious and learned author was born at Leipsick, in Saxony, in the year 1646; and though he lost his father, who was a professor in the university, at six years of age, yet availing himself of his father's library which was left him, and other advantages, he made a very considerable proficiency in general science, and was much taken notice of by the learned men of his time, when very young. In more advanced life, he was no less distinguished by his writings on the subjects of jurisprudence and theology, than on those of mathematics, metaphysics and philosophy. He died in the year 1716. The basis of Mr. Leibnitz's philosophy was that of Des Cartes; for he retained the Cartesian subtile matter, with the universal plenitude and vortices; and represented the universe as a machine that should proceed for ever, by the laws of mechanism, in the most perfect state, by an absolute inviolable necessity, though in some things he differs from Des Cartes. After Sir Isaac Newton's philosophy was published in 1687, he printed an essay on the celestial motions (Act. Erud. 1689), where he admits of the circulation of the ether with Des Cartes, and of gravity with Sir Isaac Newton; though he has not reconciled these principles, nor shewn how gravity arose from the impulse of this ether, nor how to account for the planetary revolutions and the laws of the planetary motions in their respective orbits. That which he calls the harmonical circulation is the angular velocity of any one planet, which decreases from the perihelium to the aphelium in the same proportion as the distance from the sun increases; but this law does not apply to the motions of the different planets compared together; because the velocities of the planets, at their mean distances, decrease in the same proportion as the square roots of the numbers expressing those distances. Besides, his system is defective, as it does not reconcile the circulation of the ether with the free motions of the comets in all directions, or with the obliquity of the planes of the planetary orbits; nor resolve other objections to which the hypothesis of the plenum and vortices is liable. Soon after the period just mentioned, the dispute commenced concerning the invention of the method of FLUXIONS, which led Mr. Leibnitz to take a very decided part in opposition to the philosophy of Sir Isaac Newton. From the wisdom and goodness of the Deity and his principle of a *sufficient reason*, he concluded that the universe was a perfect work, or the best that could possibly have been made; and that other things, which were incommodious and evil, were permitted as necessary consequences of what was best: the material system, considered as a perfect machine, can never fall into disorder, or require to be set right; and to suppose that God interposes in it, is to lessen the skill of the author, and the perfection of his work. He expressly charges an impious tendency on the philosophy of Sir Isaac Newton, because he asserts, that the fabric of the universe and course of nature could not continue for ever in its present state, but would require, in process of time, to be re-established or renewed by the hand of its Former. The perfection of the universe, by reason of which it is capable of continuing for ever by mechanical laws in its present state, led Mr. Leibnitz to distinguish between the quantity of motion and the force of bodies; and, whilst he owns in opposition to Des Cartes, that the former varies, to maintain that the quantity of force is for ever the same in the universe, and to measure the forces of bodies by the squares of their velocities. See FORCE.

This system also requires the utter exclusion of atoms, or of any perfectly hard and indivisible bodies; the advocates of it alledge, that according to the law of continuity, as they call a law of nature invented for the sake of the theory, all changes in nature are produced by insensible and infinitely small degrees; so that no body can, in any case, pass from motion to rest, or from rest to motion, without passing through all possible intermediate degrees of motion; whence they conclude that atoms or perfectly hard *bodies are impossible*; because if two of them should meet with equal motions, in contrary directions, they would necessarily stop at once, in violation of the law of CONTINUITY.

Mr. Leibnitz proposes two principles as the foundation of all our knowledge; the first, that it is impossible for a thing to be, and not to be at the same time, which, he says, is the foundation of speculative truth: the other is, that nothing is without a *sufficient reason* why it should be so rather than otherwise; and by this principle, according to him, we make a transition from abstracted truths to natural philosophy. Hence, he concludes, that the mind is naturally determined, in its volitions and elections, by the greatest apparent good, and that it is impossible to make a choice between things perfectly like, which he calls *indiscernibles*; from whence he infers, that two things perfectly like could not have been produced even by the Deity: and he rejects a vacuum, partly because the parts of it must be supposed perfectly like to each other. For the same reason he also rejects atoms, and all similar particles of matter, to each of which, though divisible *in infinitum*, he ascribes a *mind* (Act. Lipsiæ 1698, p. 435) or active kind of principle, endued, as he says, with perception and appetite. The essence of substance he places in action or activity, or, as he expresses it, in something that is between acting and the faculty of acting. He affirms absolute rest to be impossible, and holds motion, or a sort of *vis*, to be essential to all material substances. Each monad he describes as representative of the whole universe from its point of sight; and after all, in one of his letters, he tells us, that matter is not a substance, but a *phænomenum*, or *pheenomenon bien fondé*. He frequently urges the comparison between the effects of opposite motives on the mind, and of weights placed in the scales of a balance, or of powers acting upon the same body with contrary directions. His learned antagonist Dr. Clarke denies that there is a similitude between a balance moved by weights, and a mind acting upon the view of certain motives; because the one is entirely passive, and the other not only is acted upon, but acts also. The mind, he owns, is purely passive in receiving the impression of the motive, which is only a perception, and is not to be confounded with the power of acting after, or in consequence of, that perception. The difference between a man and a machine does not consist only in sensation and intelligence; but in this power of acting also. The balance for want of this power cannot move at all, when the weights are equal; but a free agent, he says, when there appear two perfectly alike reasonable

ways of acting, has ſtill within itſelf a power of chuſing; and it may have ſtrong and very good reaſons not to forbear. Collection of Papers which paſſed between Mr. Leibnitz and Dr. Clarke in 1715 and 1716, &c. 8vo. 1717, p. 121. See LIBERTY.

The tranſlator of Moſheim's Eccleſiaſtical Hiſtory obſerves, that the progreſs of Arminianiſm has declined in Germany and ſeveral parts of Switzerland, in conſequence of the influence of the *Leibnitzian* and Wolfian philoſophy. Leibnitz and Wolf, by attacking that liberty of indifference, which is ſuppoſed to imply the power of acting not only without, but againſt motives, ſtruck, he ſays, at the very foundation of the Arminian ſyſtem. He adds, that the greateſt poſſible perfection of the univerſe, conſidered as the ultimate end of creating goodneſs, removes from the doctrine of PREDESTINATION thoſe arbitrary proceedures and narrow views, with which the Calviniſts are ſuppoſed to have loaded it, and gives it a new, a more pleaſing, and a more philoſophical aſpect. As the Leibnitzians laid down this great end as the ſupreme object of God's univerſal dominion, and the hope to which all his diſpenſations are directed; ſo they concluded, that, if this end was propoſed, it muſt be accompliſhed. Hence the doctrine of NECESSITY, to fulfill the purpoſes of a predeſtination founded in wiſdom and goodneſs; a neceſſity, phyſical and mechanical, in the motions of material and inanimate things, but a neceſſity moral and ſpiritual in the voluntary determinations of intelligent beings, in conſequence of prepellent motives, which produce their effects with certainty, though theſe effects be contingent, and by no means the offspring of an abſolute and eſſentially immutable fatality. Theſe principles, ſays the ſame writer, are evidently applicable to the main doctrines of Calviniſm; by them predeſtination is confirmed, though modified with reſpect to its reaſons and its end; by them irreſiſtible grace (irreſiſtible in a moral ſenſe) is maintained upon the hypotheſis of prepellent motives and a moral neceſſity; the perſeverance of the ſaints is alſo explicable upon the ſame ſyſtem, by a ſeries of moral cauſes producing a ſeries of moral effects. Moſheim's Eccl. Hiſt. by Dr. Macleane, vol. v. p. 24. 8vo. edition.

For an account of Leibnitz's famous doctrine of a *pre-eſtabliſhed* HARMONY, we refer to that article.

See on the ſubject of this article Maclaurin's View of Sir Iſaac Newton's Philoſophical Diſcoveries, &c. book i. chap. 4. or p. 79, &c. quarto edition.

LEIOBATUS, in *Ichthyology*, a name given by Ariſtotle and Athenæus to a ſpecies of the ray-fiſh, called by many of the old authors *bos marinus*, and by the later authors *turtraia*, or *rana torpedo*. It is accurately diſtinguiſhed by Artedi, by the name of the variegated ray, with ten prickly tubercles on the middle of the back.

LEIOPODES, formed of λειος, *ſmooth*, and πους, *foot*, an epithet uſed by the old medical writers, to expreſs ſuch perſons who had feet perfectly ſmooth and even at the bottom, without the uſual hollow between the heel and the fore-part of the foot.

LEITURGI, Λειτουργοι, among the *Athenians*, perſons of conſiderable eſtates; who, by their own tribe, or the whole people, were ordered to perform ſome public duty, or ſupply the commonwealth with neceſſaries at their own expences.

LEMMA, Λημμα, of λαμβανω, *I aſſume*, in *Mathematics*, denotes a previous propoſition, laid down in order to clear the way for ſome following demonſtration; and prefixed either to theorems, in order to render their demonſtration leſs perplexed and intricate; or to problems, to make their reſolution more eaſy and ſhort. Thus, to prove a pyramid one third of a priſm, or parallelopiped, of the ſame baſe and height with it, the demonſtration whereof in the ordinary way is difficult and troubleſome, this *lemma* may be premiſed, which is proved in the rules of progreſſion, that the ſum of the ſeries of the ſquares, in numbers in arithmetical progreſſion, beginning from 0, and going on 1, 4, 9, 16, 25, 36, &c. is always ſubtriple of the ſum of as many terms, each equal to the greateſt; or is always one-third of the greateſt term multiplied by the number of terms. Thus, to find the inflection of a curve line, this *lemma* is firſt premiſed, that a tangent may be drawn to the given curve, in a given point.

So, in phyſics, to the demonſtration of moſt propoſitions, ſuch *lemmata* as theſe are neceſſary firſt to be allowed: that there is no penetration of dimenſions; that all matter is diviſible; and the like. As alſo in the theory of medicine, that where the blood circulates, there is life, &c.

LEMMA, λεμμα, in *Pharmacy*, a term uſed to expreſs the huſk or ſhell of certain fruits, as the almond, and the like; and in general, whatever is taken off in decortication: thus the huſks of oats, barley, &c. are the lemmata of thoſe ſeeds.

LEMMA is alſo a name given by ſome of the lower claſs of writers, in *Natural Hiſtory*, to an imaginary animal, which they deſcribe, as living in the woods of Aſia, and having the face of a woman and the body of a beaſt of prey.

LEMMA, in *Botany*, is alſo the name of a ſmall water-plant well known to the ancients, and called by Theophraſtus by this diſtinct name; but very improperly confounded by late writers among the duck-weed kinds. Called by Bauhine, Ray, Parkinſon, and others, *lenticula palluſtris quadrifolia*, the four-leaved duck-weed of Petiver, in his Gazophylacium Naturæ & Artis, *lenticula palluſtris foliis ſagittæ*, or the water-ſoldier with leaves like thoſe of wood-ſorrel.

Mr. Bernard Juſſieu has been at the pains of thoroughly inquiring into the nature and cruſtification of this plant, and to him alone we owe its true hiſtory; its flowers having never been ſeen or regarded, till that gentleman gave an account of them in the Memoirs of the Academy of Sciences of Paris; and many of the more eminent botaniſts, from its different appearance when in the water and when out of it, having miſtaken it for two different plants. It indeed differs extremely from itſelf in three different ſituations in which it is found. It is ſometimes found in the middle of large ponds of freſh water, and is then very large, fair, and full; ſometimes it is found in ſhallow-water, and is then conſiderably poorer, and ſometimes it is found on dry land, in which caſe it makes an extremely different figure; and is ſo ſtarved, and poor, as ſcarce to be known for the ſame herb.

The middle ſtate of theſe, that is when it grows in ſhallow water, ſeems its moſt natural appearance, and is the only condition in which it is found to produce its flowers and ſeeds. It is a ſpreading plant, its branches extend a great way far and wide; theſe ſend from their under part roots at certain diſtances, and from their upper four leaves ſuſtained by a long and ſlender ſtalk, and uſually there are ſeveral of theſe ſtalks from the ſame part of the plant, from the ſame parts of the branches from whence the leaves ariſe; there are alſo ſeen to ariſe other very ſlender and very ſhort ſtalks which bear ſmall capſules, within which is incloſed the flower, and afterwards the ſeed. The flowers are placed in ſeveral looſe ſegments in this ſhell, and are compoſed of ſtamina and piſtils, but have no petals. The piſtils are various in number in the different flowers from three to eight; the ſtamina are always very minute and very numerous. Mem. de l'Acad. Scien. Par. 1740.

Plukenet has deſcribed this plant very differently from this writer, but the difference ſeems only owing to this, that Plukenet deſcribed one he found in deep water, whereas Mr. Juſſieu formed his account from the more ordinary and perfect appearance of the plant in ſhallow water, where alone it ripens its flowers and ſeeds. We have it not in England, ſo far as is yet known, but it is common in the Eaſt and Weſt-Indies, and in France.

LEMMER, or LEMMING, in *Zoology*. See *Sable* MOUSE.

LEMNA. See DUCK-*weed*.

LEMNIAN *earth*, *Lemnia terra*, a kind of BOLE or fine earth uſed in medicine, of which there are three ſpecies, the white, the yellow and the red; but the red is moſt uſed. The characters by which they may be diſtinguiſhed from all other earths of the ſame colours are theſe:

Red *Lemnian earth* is a denſe compact earth of a cloſe firm texture, and pale red colour, and, when ſcraped, of a ſmooth and even, but not gloſſy ſurface. It does not break readily between the fingers, nor at all ſtain the hands; it is not readily diffuſible in water; melts ſlowly in the mouth; is very aſtringent to the taſte, and when in its native ſtate, is always ſomewhat harſh and gritty between the teeth; for what we find of it that is perfectly pure and free from ſand, is ſuch as has been waſhed and ſeparated from it, all the genuine earth naturally containing ſome. It adheres firmly to the tongue, raiſes a ſlight effervecence with aqua fortis, and acquires a conſiderable hardneſs, and burns to a fine deep red colour in the fire.

This is dug in the iſland of Lemnos, and in no other place, ſo far as is yet known; and the fine and true earth only in one pit, which is opened once every year, and no oftener, with great ſolemnity; and the earth, ſuppoſed ſufficient for the year's demand, is taken out and ſold to the merchants; ſome ſealed with various figures, other quantities unſealed; but what is there bought unſealed, is generally formed into ſmall maſſes, and ſealed before it is offered to ſale in Europe, the druggiſts ſuſpecting to find *Lemnian earth* ſealed.

This is a valuable earth, but it is too often adulterated frequently by the Turks upon the ſpot, either by mixing with other earths, or another earth alone being ſold in its place; but more frequently in Europe, where even wholeſale

wholesale dealer knows how to make a composition of his own clays, and properly tinge them with ochre, and afterwards give an impression resembling that of the genuine.

This earth was celebrated by the ancients as a sovereign remedy against poisons: and the Turks still retain that notion, for the cups out of which the grand seignior drinks, are made of this red earth, so that it is reserved chiefly for the sultan's use. But the alexipharmic and astringent property of this and the other boles is now in little or no esteem.

The white *Lemnian earth* is a fine bole of a dirty whitish hue with an ashen cast, and some very slight reddish streaks, of a coarse firm texture, and very heavy. It is not in the least unctuous or smooth, not even when prepared, but of a rough harsh surface; it scarce at all stains the fingers in handling, crumbles to pieces with difficulty, is difficultly diffusible in water, and melts in the mouth also, with difficulty; it is extremely impure and gritty, has a fine astringent taste, and scarcely adheres to the tongue when applied to it. This makes no effervescence with acids. In burning it acquires a great hardness, and outwardly is of a deep blackish brown, but inwardly of a deep brownish yellow colour. It is dug in the island of Lemnos, and used in the German shops as an astringent and sudorific, and said to be of great efficacy in dysenteries, hæmorrhages, and malignant fevers. The ancients knew this kind, but never used it in medicine, esteeming the other superior, but they employed it as the cimolia in cleaning linen and woollen cloths.

The yellow *Lemnian earth* is a very valuable earth, common in the shops, and more than all the other substances of this kind subject to be counterfeited.

It is a very pure and fine earth, of a lively florid yellow, of a close compact texture and smooth surface, considerably hard, and not at all staining the fingers in handling. It sticks firmly to the tongue, and melts pretty readily in the mouth, leaving not the least harshness between the teeth, and does not ferment with acid menstrua. In the fire it acquires a considerable hardness, and dusky colour. It is counterfeited two ways; the one by a yellow ochre, which may be discovered by its staining the hands, and the other by a yellow clay; but this is easily known by its want of the true florid colour, and having all the characters of a clay, not a bole. The genuine is found only in the island of Lemnos, and is the stratum next above the red. It is esteemed a sudorific, astringent and vulnerary. Hill's Hist. of Fossils, p. 8 and 13. Da Costa's Hist. of Fossils, p. 1. 14. and 22.

LEMNISCATE, in the *Higher Geometry*, is the name of a curve which has the form of the figure of 8. If we call AP, *x*, *Tab.* III. *Analysis*, *fig.* 62. and PM, *y*, and the constant line BC, *a*, the equation of the curve will be $ay = x\sqrt{aa - xx}$ or $a^2yy = a^2x^2 - x^4$, which is an equation of the fourth degree: it is also evident that a right line which passes through the double point A will cut this curve in four points, the double point being reckoned equal to two. See CURVE.

LEMON, *limon*, in *Botany*, derives its name from λειμων, *a meadow*, because the leaves of this tree and its fruit before it comes to maturity are of a green colour. Linnæus has joined this genus to the *citrus* or CITRON-*tree*. Indeed the terms citron and *lemon* have been often confounded together. What is commonly called citron by the French and Germans being our *lemon*, and their *lemon* our citron. Its characters are these: the flower is composed of five oblong thick petals which are a little concave and spread open; these sit in a small empalement of one leaf, indented in five parts at the top: it has about ten or twelve stamina, which are joined in three or four bodies; terminated by oblong summits; and an oval germen, which becomes an oval fruit with a fleshy rind, inclosing a thin pulp with several cells, each having two hard seeds: there are three species.

There are great varieties of this fruit, which are preserved in some of the Italian gardens; and in both the Indies there are several which have not yet been introduced into the European gardens: but these like apples and pears may be multiplied without end from seeds.

The common *lemon* and the sweet *lemon*, are brought to England from Spain and Portugal in great plenty; but the fruit of the latter is not much esteemed. The lime is not often brought to England, nor is that fruit much cultivated in Europe; but in the West Indies it is preferred to the *lemon*; the juice being reckoned wholesomer, and the acid more agreeable to the palate. The *lemon* and lime appear to be of different species.

The culture of the *lemon* is much the same with that of the ORANGE, but being somewhat harder, they will bring their fruit better to maturity with us, and require a greater share of fresh air in winter. Miller.

Lemons are cooling and grateful to the stomach, quenching thirst, and increasing appetite; useful in fevers, as well common as malignant and pestilential: they also provoke urine. The juice mixed with salt of wormwood, is an excellent medicine to stop vomiting, and to strengthen the stomach. The yellow rind is a grateful aromatic, and commonly used in stomachic tinctures and infusions, and for rendering other medicines acceptable to the palate and stomach. In distillation it yields an essential oil, extremely light, almost colourless, frequently employed as a perfume, and brought to us from the southern parts of Europe, under the name of essence of *lemons*. Six drams of the juice of *lemons* saturated with about half a dram of fixt alkaline salt, with the addition of a small quantity of some grateful aromatic water, as tincture of simple cinnamon water, is given in cases of nauseæ, reachings, and generally abates, in a little time, the severe vomitings that happen in fevers, when most other liquors and medicines are thrown up as soon as taken. It is also used as a saline aperient in ictherical, hydropical, inflammatory, and other disorders. A syrup made by dissolving forty-eight or fifty ounces of fine sugar in a quart of the depurated juice, is mixed occasionally with draughts and julaps, as a mild antiphlogistic, and sometimes used in gargarisms for inflammations of the mouth and tonsils. Lewis Mat. Med.

LEMONADE, a drink prepared of water, sugar, and citron, or lemon-juice.

This factitious liquor is so popular in Paris, that it has given its name to a new established company, called *lemonadiers*.

LEMUR, in *Zoology*, is a genus of the order of PRIMATES, in the class of *mammalia*. The animals of this genus have four upper fore-teeth, separate from each other, and six lower ones, which are longer, compressed, and parallel; the lanatii are single ones, and the molares are many, the fore ones being longer and sharper than the others. See LORIS, MAUCAUCO, and MONGOOZ.

LEMURES, in *Antiquity*, *sprites* or *hobgoblins*; restless ghosts of departed persons, who return to terrify and torment the living.

These are the same with *larvæ*, which the ancients imagined to wander round the world, to frighten good people, and plague the bad. For which reason, at Rome they had *Lemuria*, or feasts instituted to appease the manes of the defunct. See LARES.

Apuleius explains the ancient notion of manes thus: the souls of men, released from the bands of the body, and freed from performing their bodily functions, become a kind of dæmons or genii, formerly called *lemures*. Of these *lemures*, those that were kind to their families, were called *lares familiares*; but those who, for their crimes, were condemned to wander continually, without meeting with any place of rest, and terrified good men, and hurt the bad, are vulgarly called LARVÆ.

An ancient commentator on Horace mentions, that the Romans wrote *lemures* for *remures*; which last word was formed from Remus, who was killed by his brother Romulus, and who returned to earth to torment him.

But Apuleius observes, that in the ancient Latin tongue *lemures* signifies the soul of a man separated from the body by death.

LEMURIA, or LEMURALIA, a feast solemnized at Rome on the ninth of May, to pacify the manes of the dead, or in honour of the lemures.

The institution of this feast is ascribed to Romulus, who, to rid himself of the phantom of his brother Remus (whom he had ordered to be murdered) appearing always before him, ordained a feast, called after his name *Remuria*, or *Lemuria*.

In the *Lemuria* they offered sacrifices for three nights together; during which time all the temples of the gods were shut up, nor were any marriages permitted. There were many ceremonies in this feast, chiefly intended to exorcise the lemures, and prevent their appearing, or giving any disturbance, to the living.

LENÆA, Ληναια, in *Antiquity*, a festival of Bacchus, surnamed *Lenæus*, from ληνος, i. e. a *wine-press*. Besides the usual ceremonies at feasts sacred to this god, it was remarkable for poetical contentions, and tragedies acted at this time. Potter's Archæol. lib. ii. cap. 20. tom. i. p. 417.

LENGTH, in the *Manege*. *To passage a horse upon his own length*, is to make him go round in two treads, at a walk or trot, upon a spot of ground so narrow, that the horse's haunches being in the center of the volt, his own *length* is much about the semidiameter of the VOLT; the horse still working between the two heels, without putting out his croupe, or going at half faster or slower than at *first*.

LENGTHENING, in *Naval Architecture*, denotes the operation of cutting a ship down across the middle, and adding a certain portion to her length. This is performed by sawing her planks asunder, in different places of her

length, on each side of the midship frame, to prevent her from being weakened too much in one place; the two ends are then drawn apart, to a limited distance, which must be equal to the propoſed addition of length. An intermediate piece of timber is next added to the keel, upon which a ſufficient number of timbers are erected, to fill up the vacancy produced by the ſeparation. The two parts of the keelſon are afterwards united by an additional piece, which is ſcored down upon the floor-timbers; and as many beams as may be neceſſary are fixed acroſs the ſhip in the new interval. Finally, the planks of the ſide are prolonged, ſo as to unite with each other, and thoſe of the ceiling refitted in the ſame manner; by which the whole proceſs is completed. Falconer.

LENIS *ſpiritus*, in *Phyſics*. See SPIRIT.

LENITIVE, in *Phyſic*, ſometimes denotes a ſoftening, reſolutive remedy, that moiſtens the parts diſeaſed, and diſſipates any ſharp humour collected there.

LENITIVE is more frequently uſed for LAXATIVE.

LENITIVE *electary* is more peculiarly uſed for a gentle purging electary, compoſed of eight ounces of ſena, in powder, coriander-ſeeds, in powder, four ounces, mixed with pulp of tamarinds and of French prunes, of each a pound, and a ſufficient quantity of ſimple ſyrup, to reduce the whole into an electary. It is ſo called, becauſe it purges eaſily, and by reſolving.

A tea-ſpoonful of this electary taken two or three times a day generally proves an agreeable laxative. It likewiſe ſerves as a convenient vehicle for exhibiting more active medicines, as jalap, ſcammony, &c.

LENS, in *Dioptrics*, properly ſignifies a ſmall, roundiſh glaſs, of the figure of a *lentil*; but is extended to any optic glaſs, not very thick, which either collects the rays of light into a point, in their paſſage through it, or diſperſes them farther apart, according to the laws of refraction.

Lenſes have various figures; that is, are terminated by various ſurfaces, from which they acquire various names. Some are plane on one ſide, and convex on the other; others convex on both ſides; both which are ordinarily called *convex lenſes*; though, when we ſpeak accurately, the former are called *plano-convex*, and the latter *double convex*. Again, ſome are plane on one ſide, and concave on the other; and others are concave on both ſides, which are both uſually ranked among the concave *lenſes*; though, when diſtinguiſhed, the former is called a *plano-concave*, and the latter a *double concave*. Others, again, are concave on one ſide, and convex on the other; which are called *convexo-concave*, or *concavo-convex lenſes*, according as the one or the other ſurface is more curve, or a portion of a leſs ſphere.

When the particular figure is not conſidered, a *lens* that is thickeſt in the middle is called a *convex lens*; and that which is thinneſt in the middle is called a *concave lens*, without farther diſtinction.

It is to be here obſerved, that in every *lens* terminated in any of the forementioned manners, a right line perpendicular to the two ſurfaces is called the AXIS of the *lens*; which axis, when both ſurfaces are ſpherical, paſſes through both their centres; but if one of them be plane, it falls perpendicularly upon that, and goes through the center of the other. The points where the axis cuts the ſurface are called the vertices of the *lens*, and the middle points between them is called the center.

A *lens*, one of whoſe ſurfaces is convex, and the other concave, is called a *meniſcus*; the properties of which, ſee under MENISCUS.

See alſo the *Theory of* LENSES *demonſtrated* under REFRACTION; and the application thereof under MICROSCOPE, TELESCOPE, BURNING-GLASS, and FOCUS.

Some confine *lenſes* within the diameter of five or ſix lines, and will have ſuch as exceed that diameter called *lenticular glaſſes*.

Lenſes are diſtinguiſhed, with regard to the manner of their preparation, into *ground* and *blown*.

LENSES, *blown*, are little globules of glaſs, melted in the flame of a lamp, or taper. See MICROSCOPE.

LENSES, *manner of grinding*. A little piece of copper is cemented to the end of the arbor of a lathe, and turned, till it form a diſh, or baſon, of the diameter of the *lens* required. Then a piece of clear glaſs is cemented on one of its flat ſides, to the end of a little maundrel, with black Spaniſh wax; and thus ground, on the ſide not cemented, on a grindſtone, with water, till it have nearly acquired a convex figure. It is finiſhed in the lathe, by turning it in the baſon, with fine wet ſand, or grit-ſtone. The grit muſt be often repeated freſh till the *lens* appear very round; when it is come to that point, they ceaſe to take any freſh ſtone, but continue to turn it in the baſon, till the remains of the ſand be become ſo fine as to have poliſhed it. This they perceive, when, upon wiping it, the image of the window of the place is ſeen painted on its ſurface; if it does not, it is wetted in water without any ſand, and turned till it have got a poliſh. The baſon is then covered, withinſide, with two or three folds of linen, and the poliſh finiſhed with putty, or tripoly of Venice ſteeped in water. It is known to be perfectly poliſhed, when, viewing it with a magnifier, there appear no ſcratches of the ſand. The cement is then broken off, and the ſide poliſhed cemented, ground, and grind the other, as before, till the edges of the *lens* be become ſharp, and it be perfectly poliſhed on that ſide. When finiſhed, it is waſhed in ſpirit of wine, to take off all remains of the wax.

In the Philoſophical Tranſactions we have the figure of a machine for grinding *lenſes* ſpherically. It is a contrivance to turn a ſphere at one and the ſame time on two axes, interſecting each other at right angles, with an equal velocity and preſſure on each. See the Tranſactions, N° 439. ſect. 1. See GRINDING of *Optic Glaſſes*.

LENSES, *for convex*, the laws of their refraction, and their effects depending thereon, are as follow. 1. A ray of light, EG, near the axis (*Theo. Optics, fig.* 1.) and parallel thereto, ſtriking on the plane ſurface of a plano-convex *lens*, directly oppoſite to the luminous body, after refraction concurs with the axis in the point F: and if C be the centre of the convexity, CF will be to FL, that is, the diſtance of the centre from the point of concourſe, or focus, will be to the diſtance of the centre in the convex ſurface, in the ratio of the refraction.

For the plane ſurface being directly oppoſed to the luminous body, the ray EG is perpendicular to AB, and therefore will paſs unrefracted to H: thus it ſtrikes on AHB, ſtill parallel to the axis; and therefore coming out of a denſer medium into a rarer, it will meet with the axis of the *lens* in F; and ſo as that CF will be to FL in the ratio of the ſine of the refracted angle to the ſine of the angle of incidence: as will be demonſtrated under the head REFRACTION.

And, therefore, CF—FL or CL is to FL as the difference of theſe lines is to the ſine of the angle of incidence; and CF—FL or CL is to CF as the ſame difference is to the ſine of the refracted angle.

If then the refraction be out of a glaſs *lens* into air, CF: FL::3:2, or CL: FL::1:2; and therefore FL=2 CL; that is, parallel rays, near the axis, will concur with it at the diſtance of the diameter. Again, if the refraction were out of a water *lens*, i. e. out of a plano-convex *lens* filled with water, CF: FL::4:3, or CL: FL::1:3; and therefore FL=3 CL; i. e. parallel rays, near the axis, will concur with it at the diſtance of a diameter and a half. So that if a lighted candle be placed in the focus of a plano-convex *lens*, that is, in the point F, diſtant from the ſurface of the *lens* ALB, by the length of the diameter; and from the ſurface of the water *lens*, by a diameter and a half, its rays, after refraction, will become parallel.

2. If the ray KI (*Theo. Optics, fig.* 2.) near the axis of a plano-convex *lens*, and parallel thereto, ſtrike on its convex ſurface AHB, after a double refraction, it will meet the axis in F; ſo as that HG will be to GC, and GD to FD, in the ratio of the refraction.

For the ray KI, parallel to the axis EG, by virtue of the firſt refraction in I, will tend to the point G, ſo that GH will be to GC in the ratio of the ſine of the angle of incidence to the ſine of the refracted angle: therefore, by virtue of the ſecond refraction in I, it will concur with the axis in F; ſo that GD will be to FD in the ratio of the ſine of the refracted angle, to the ſine of the angle of incidence. See REFRACTION.

So that the ſemidiameter, and thickneſs of the plano-convex *lens*, with the ratio of refraction, being given, hence ariſes a method of determining the focus of parallel rays ſtriking on the convex ſurface. For, if the ratio of refraction be expreſſed by $n:m$, HG: GC::$n:m$; therefore $n-m:n$::HC: HG; and HG$=\frac{n}{n-m}\times$HC: from which ſubtracting the thickneſs of the *lens* DH, and GD$=\frac{n}{n-m}\times$HC—HD. Then ſince the ratio of GD to FD is the given ratio of refraction, FD$=\frac{m}{n-m}$CH—$\frac{m}{n}$HD$=$ (rejecting the quantity $\frac{m}{n}$HD as very ſmall) $\frac{m}{n-m}$CH.

Hence, if the *lens* be glaſs, FD$=2$CH—HD. So that if two-thirds of the thickneſs of the *lens* be inconſiderable (as in practice it uſually happens), parallel rays meet with the axis at the diſtance of the diameter from the *lens*, even when they ſtrike at the convex ſurface. So that, as to the place of the focus, it is no matter whether the plane ſurface, or the convex, be turned to a luminary of parallel rays; though it appears both

both from experience and trigonometrical calculations, that there are more rays united in a leſs ſpace, if the convex ſurface, than if the plane one, be turned towards the ſun.

If the *lens* were full of water, $FD=\frac{3}{4}CH-\frac{1}{4}HD$, wherefore if $\frac{1}{4}HD$ be inconſiderable, $FD=\frac{3}{4}CH$, or if $\frac{1}{4}HD$ be inconſiderable, $FH=\frac{3}{4}CH$. Parallel, and near rays, therefore, are united at the diſtance of a diameter and a half, if the refraction be in water, even when the convex ſurface is oppoſed to the luminous body.

3. Hence, alſo, ariſes a method of determining the focus of parallel rays ſtriking on a *lens* convex on both ſides, the two ſemidiameters, and the thickneſs of the *lens*, being given.

For if the ray HI, *Tab.* II. *Optics*, *fig.* 32) near the axis DG and parallel to it, fall on a *lens* convex on both ſides, after a double refraction, it will meet the axis in F, provided that GE : GC and DK : DO have the ratio of refraction. And GD will be to GK as GO to GF. Since EG : GC in the ratio of refraction, the ray HI will tend to the point G; and if DK be to DO in the ratio of refraction, after the ſecond refraction at its egreſs, it will meet the axis in F, and GD : GK :: GO : GF. See REFRACTION.

And therefore, GK : DK :: GO : FO. Let the ratio of refaction be that of $n:m$, then GE : GC :: $n:m$, and DK : DO :: $n:m$; and, therefore, $n-m:n::CE:GE$, and $n-m:n::KO:DK$; wherefore if the ratio of refraction and the ſemidiameters CE and KO are given, GE and DK may be found: and ſince GD = DK + EG − EK, and GK = GE − EK, and GO = GE + KO − EK, and GD : GK :: GO : GF; GF may be found: moreover GE − GF = EF. If EK be rejected as very ſmall, GD = DK + EG, GK = GE, and GO = GE + KO; and therefore, DK + EG : GE :: GE + KO : GF. Hence, if the *lens* be glaſs, ſince GE = 3 CE, and DK = 3 KO, 3 KO + 3 CE : 3 CE :: 3 CE + KO : GF; conſequently KO + CE : CE :: 3 CE + KO : GF. And ſubſtituting for KO, a, CE, b, and GF, x, $x=\frac{3bb+ab}{a+b}$, and FE or FK, (rejecting EK) $=3b-\frac{3bb+ab}{a+b}=\frac{3ab+3bb-3bb-ab}{a+b}=\frac{2ab}{a+b}$; therefore the ſum of the ſemidiameters KO + CE is to the double of one of them, or 2 CE, as the other KO is to FK the diſtance of the focus from the *lens*.

If the glaſs *lens* were equally convex on both ſides, then KO = CE, and 2 CE : CE :: 4 CE : GF, and therefore, $GF=2CE$; and $FK=\frac{2a^2}{2a}=a=EC$: *i. e.* the diſtance of the focus from the *lens* is equal to the radius of convexity.

If the *lens* were full of water, ſince GE = 4 CE, and DK = 4 KO, 4 KO + 4 CE : 4 CE :: 4 CE + KO : GF; conſequently KO + CE : CE :: 4 CE + KO : GF. Wherefore ſubſtituting as before $x=\frac{4bb+ab}{a+b}$, and FE or FK $=4b-\frac{4bb+ab}{a+b}=\frac{3ab}{a+b}$; conſequently the ſum of the ſemidiameters KO + CE is to the triple of either 3 CE as the other KO is to FK, the diſtance of the focus from the *lens*.

If this *lens* were equally convex on both ſides, we ſhould have 2 CE : CE :: 5 CE : GF; therefore $GF=\frac{5}{2}CE$; and $FK=\frac{3a^2}{2a}=\frac{3}{2}a$; i. e. the diſtance of the focus from the *lens* is two-fifths of the radius.

On theſe principles is founded the ſtructure of refracting BURNING-*glaſſes*, the ſun's light and heat being exceedingly augmented in the focus of the *lens*, whether convex or plano-convex; ſince the rays, falling parallel to the axis of the *lens*, are reduced into a much narrower compaſs; ſo that it is no wonder they burn ſome bodies, melt others, and produce other extraordinary phænomena.

4. If a luminous body be placed in a focus behind a *lens*, whether plano-convex, or convex on both ſides; or whether equally or unequally; the rays, after refraction, become parallel. In this caſe the refracted rays become the incident rays, and *vice verſa*, and conſequently the refracted are parallel.

Hence, by means of a convex *lens*, or a little glaſs bubble full of water, a very intenſe light may be projected to a vaſt diſtance.

And this furniſhes us with the ſtructure of a lamp, or lantern, to project an intenſe light to an immenſe diſtance: for a *lens*, convex on both ſides, being placed oppoſite to a concave mirror, if in the common focus of both be placed a lighted candle, or wick, the rays reflected back from the mirror to the *lens* will be parallel to each other; and after refraction will converge, till they concur at the diſtance of the ſemi-diameter, after which they will again diverge.—But the candle being likewiſe in the focus of the *lens*, the rays it throws on the *lens* will be parallel: and therefore a very intenſe light meeting with another equally intenſe, at the diſtance of the diameter from the *lens*, the light will be ſurpriſing: and though it afterwards decreaſe, yet the parallel and diverging rays going a long way together, it will be very great at a very great diſtance. Lanterns of this kind are of conſiderable ſervice in the night time to diſcover remote objects, and are uſed, with ſucceſs, by fowlers and fiſhermen, to gather their prey together, in order to take them.

If it be required to have the light, at the ſame time, tranſmitted to ſeveral places, as through ſeveral ſtreets, *&c.* the number of *lenſes* and mirrors is to be increaſed.

If the luminous body, placed in the focus, be of a larger extent, the rays flowing from points ſenſibly diſtant from each other, cannot be parallel; but they will conſtitute ſeveral trains, or parcels of rays, parallel to each other.

5. The images of objects, oppoſed in any manner to a convex *lens*, are exhibited, inverſedly, in its focus.

Hence, if a paper be applied to a convex *lens* (eſpecially in a dark room) at the diſtance of its focus, the images of objects ſhining upon it will be repreſented diſtinctly, and in their natural colours, thereon: nor is the focus of the ſun's rays any thing elſe, in effect, but the image of the ſun.—Hence, in ſolar eclipſes, the ſun's image, eclipſed as it is, may be burnt by a large *lens* on a board, *&c.* and exhibit a very entertaining phænomenon.

Hence alſo, if a convex *lens*, of any kind, be expoſed both to nearer and remoter objects, and a paper at the ſame time be applied, ſo as to receive the images of objects diſtinctly, the diſtance of the focus from the *lens*, and thence the diameter of the convexity, may be determined.

6. If a concave mirror be ſo placed, as that an inverted image, formed by refraction through a *lens*, be found between the centre and the focus, or even beyond the centre, it will again be inverted by reflexion, and ſo appear erect in the firſt caſe beyond the centre; and in the latter, between the centre and the focus. On theſe principles is conſtructed the CAMERA *obſcura*.

7. The diameter of the image of an object deſcribed beyond a convex *lens*, is to the object itſelf in the ratio of the diſtance of the image to that of the object.

Since then the image of a remoter object is leſs diſtant from the *lens* than that of the nearer, the image of the more remote will be leſs than that of the nearer. And becauſe the diſtance of the image from the *lens* is greater, if the *lens* be a ſegment of a greater ſphere than of a leſs; hence the image will be greater in the former caſe than in the latter. The image therefore will be of ſuch a magnitude, as it would be of, were the object to ſhine into a dark room through a little hole upon a wall, at the ſame diſtance from the hole, at which the focus is from the *lens*.—When an object is leſs diſtant from a *lens* than the focus of parallel rays, the diſtance of the image is greater than that of the object; otherwiſe, the diſtance of the image is leſs than that of the object: in the former caſe, therefore, the image is greater than the object; in the latter, leſs.

If the images be made greater than the objects, they will not appear diſtinctly; becauſe in that caſe there are fewer rays which meet after refraction in the ſame point; whence it happens, that rays proceeding from different points of an object terminate in the ſame point of an image, which is the cauſe of confuſion.—Hence it appears, that the ſame aperture of a *lens* may be admitted in every caſe, if we would keep off the rays which produce confuſion. However, though the image is then more diſtinct, when no rays are admitted but thoſe near the axis, yet for want of rays the image is apt to be dim.

8. If the eye be placed in the focus of a convex *lens*, an object viewed through it appears erect, and enlarged in the ratio of the diſtance of the object from the eye, to that of the eye from the *lens*, if it be near; but infinitely, if remote.

LENSES, *for concave, ſee* CONCAVE *lenſes* are as follow.—1. If parallel rays ſtrike on a plano-convex *lens* KL, and FC be to FB in the ratio of refraction, the rays will diverge from the axis; and the point of divergency, or diſperſion, called the *virtual* FOCUS, will be F. See *Tab. Opticks*, *fig.* 3.

For the ray HI, parallel to the axis, is perpendicular to KL, and will therefore paſs unrefracted to E. Wherefore, FC being to FB in the ratio of refraction, F will be the virtual focus.

If then the *lens* be glaſs, $FB=2BC$; *i. e.* the virtual focus F will be diſtant from the *lens* KL by the ſpace of the diameter 2 BC.

If the refraction be in water, $FB=\frac{3}{2}BC$; *i. e.* the vir-

tual focus F will be diſtant from the *lens* KL a diameter and a half 3BC.

2. If the ray AE, parallel to the axis FP, ſtrike on a *lens* concave on both ſides; and both FC be to FB, and IP to PH in the ratio of refraction; and FP: PH :: FB: BG; G will be the point of diſperſion, or the virtual focus. See *Tab. Optics, fig.* 4.

If therefore, the ratio of the refraction be $=n:m$, CB $=a$, and $IH=b$; $FB=\frac{ma}{n-m}$, and $PI=\frac{nb}{n-m}$; conſequently, diſregarding the thickneſs of the *lens*, FP $=FB+IP=\frac{na+nb}{n-m}$, and $PH=PI-IH=\frac{nb}{n-m}-b$ $=\frac{mb}{n-m}$: therefore, $\frac{n\times a+b}{n-m}:\frac{mb}{n-m}::\frac{na}{n-m}:BG$; i. e. $a+b:\frac{mb}{n-m}::a:BG$, or, $n-m\times a+b:mb::a:BG$; i. e. $\overline{n-m\times CB+IH}:m\,IH::CB:BG$.

If therefore the refraction be in a glaſs *lens*, ſo that $m=2$, $n=3$, and $a+b=2b:a:BG$; the ſums of the ſemidiameters CB and HI, will be to the diameter of the concavity of either, 2HI, as the ſemidiameter of the other CB, to the diſtance of the virtual focus from the *lens*, BG.

But if the ſemidiameters HI and CB are equal, or $a=b$, $BG=\frac{2a^2}{2a}=a$; or BG, the diſtance of the virtual focus from the *lens*, is equal to the ſemidiameter CB or HI. If the refraction be made in water, $m=3$ and $n=4$, and therefore, $a+b:3b::a:BG$; i. e. the ſum of the ſemidiameters CB and HI will be to a diameter and a half of either concavity, 3HI, as the ſemidiameter of the other CB to BG, the diſtance of the virtual focus from the *lens*: in this caſe, if $a=b$ or HI $=CB$, $BG=\frac{3a^2}{2a}=\frac{1}{2}a=\frac{3}{2}CB$ *i. e.* the diſtance of the virtual focus from the *lens*, BG, is to the ſemidiameter BC in a ſeſquialteral ratio.

Hence, the ſun's rays, ſtriking on a concave *lens*, their light, after refraction, will be conſiderably weakened; ſo that the effect of concave *lenſes* is oppoſite to that of the convex ones.

3. An object viewed through a concave *lens* appears erect, and diminiſhed in a ratio compounded of the ratios of the ſpace in the axis between the point of incidence, and the point to which an oblique ray would paſs without refraction, to the ſpace in the axis between the eye, and the middle of the object; and the ſpace in the ſame axis between the eye and the point of incidence, to the ſpace between the middle of the object, and the point the oblique ray would paſs to without refraction.

Though the properties of *lenſes* have been here conſidered principally with regard to rays falling near the axis, and parallel thereto; yet the reaſoning will be eaſily tranſferred to rays remoter from the axis, and falling, in any direction.—Thus we may ſay univerſally, that in a convex *lens*, all parallel rays become converging, and concur in a focus; that diverging rays either become leſs diverging, or run parallel, or converge; and that converging rays converge the more: all which alterations are more ſenſible in oblique rays, than in perpendicular ones, becauſe the angles of incidence in that caſe are greater.

In concave *lenſes* all parallel rays become diverging, and all diverging rays diverge more; converging rays either converge leſs, or become parallel, or go out diverging; all which things hold of oblique as well as direct rays, but more ſenſibly in the firſt.

LENS, or LENTICULA, was alſo the name of a kind of weight among the Romans; being the hundred and eighth part of a drachm; equal to a grain and a half.

LENS, the *lentil*, in *Botany*. See LENTIL.

LENS *paluſtris*, in *Botany*. See DUCK's *meat*.

LENT, *Quadrageſimo*, a time of mortification, during the ſpace of forty days, wherein Chriſtians are enjoined to faſt, in commemoration of our Saviour's miraculous faſting ſo long in the deſert, and by way of preparation for the feaſt of Eaſter.

In the ancient Latin church, *Lent* only conſiſted of thirty-ſix days. In the ninth century, to come ſomewhat nearer to the miracle, ſeveral took upon them to add four days more; which in time became a general practice; though the church of Milan is ſaid ſtill to take up with the ancient thirty-ſix.

According to S. Jerom, S. Leo, S. Auguſtine, and others, *Lent* muſt have been inſtituted by the apoſtles. Their way of reaſoning is thus: whatever is generally received throughout the whole church, and whoſe inſtitution we do not find in any council, muſt be eſteemed to have been eſtabliſhed by the apoſtles. Now ſuch, they ſay, is the faſt of *Lent*. Its inſtitution is not ſpoken of in any council; but many of the ancient councils, particularly that of Nice, that of Laodicea, &c. and ſome of the oldeſt fathers, particularly Tertullian, ſpeak of it as a thing of ſome ſtanding.

The Reformed, generally, hold *Lent* to be a ſuperſtitious inſtitution, ſet on foot by ſome vain enthuſiaſts, who durſt undertake to ape the miracles of Jeſus Chriſt; as, in effect, it appears to have been from a paſſage of Irenæus, quoted by Euſebius.

Some will have it to have been firſt inſtituted by pope Teleſphorus, in the ſecond century: others, who own that there was a kind of abſtinence obſerved in the ancient church before Eaſter, yet contend that it was entirely voluntary, and was never enjoined by any law till the third century. See FAST.

This religious ſeaſon is ſaid to have been firſt obſerved in England by our Saxon anceſtors in the year 640. Anderſon's Hiſt. of Commerce, vol. i. p. 25.

Political *Lents* have been often enjoined by ſtatute and royal proclamation. See ABSTINENCE.

King James I. iſſued a proclamation againſt eating fleſh in *Lent* in 1619, and another in 1625. A ſimilar proclamation was alſo iſſued by Charles I. in 1627 and another in 1631.

There was ſome difference between the practice of the Greek and Latin churches as to the buſineſs of *Lent*; the Greeks beginning it a week ſooner, but at the ſame time allowing more days of intermiſſion than the Latins: thoſe who held it ſeven weeks did not faſt on Saturdays, as thoſe who obſerved it but ſix did.

The ancient Latin monks had three *Lents*; the grand *Lent* before Eaſter, another before Chriſtmas called the *Lent of S. Martin*; and a third after Whitſunday, called the *Lent of St. John Baptiſt*; each of which conſiſted of forty days.

The Greeks, beſides that before Eaſter, obſerved four others; that of the *Apoſtles*, of the *Aſſumption*, of *Chriſtmas*, and of the *Tranſfiguration*: but they reduced each of them to the ſpace of ſeven days.—The Jacobites added a fifth, which they called the *Repentance of Nineveh*; and the Maronites a ſixth, called the *Exaltation of the Holy Croſs*.

By the ninth canon of the eighth council of Toledo, it is ordained, "That if any perſons, without evident neceſſity, "eat fleſh in *Lent*, they ſhall be deprived the uſe of it "all the reſt of the year."

By the fifth chapter of the fourteenth ſeſſion of the council of Trent, confeſſion is enjoined as peculiarly fit and acceptable at this ſeaſon. Hard. Conc. tom. x. p. 93.

The forty days in *Lent*, ſay ſome, are obſerved in remembrance of the forty days wherein the world was drowned; or, as others ſay of the forty years wherein the Jews wandered in the deſert; others, of the forty days allowed Nineveh for repentance; others, of the forty ſtripes by which malefactors were to be corrected; or, the forty days during which Moſes faſted at the receiving of the law; or the forty days faſt of Elias; or, finally, the forty days faſt of our Saviour.

LENTES *lapideæ*, *foſſile lentils*, the name given by many writers to a very remarkable foſſile ſubſtance, uſually found immerſed in hard ſtones, and of a roundiſh but flatted ſhape, reſembling not unaptly a pea or *lentil* flatted by preſſure. They generally lie in great quantities in the ſame maſs of ſtone; and are of a very different appearance, when their ſides or ends are ſeen, from that which they exhibit, when their flat ſurfaces come in view.

They are generally ſuppoſed to be *lentils* petrified and bedded in ſtone, and as their ſides come in view in ſome parts of the maſſes, they are not perceived to be a part of the ſame ſubſtances, but are called the remains of ſeeds of other plants, and the whole ſtone is uſually named *lapis frumentarius*.

We are not to ſuppoſe, that ſo ſoft a body as the *lentil* ſeed, or a common pea, could be eaſily petrified and preſerved in its own form in ſtone; ſince if theſe ſoft ſubſtances were readily capable of ſuch a change, they are ſo very common in their recent ſtate, that they muſt be expected to be found in this foſſile condition very frequently alſo, and in great variety. This, however, is not the caſe. But this improbability is not all the reaſon we have to conjecture, that theſe are not what they are vulgarly ſuppoſed to be, that is, foſſile ſeeds; for a ſtricter examination of the things themſelves proves this to be impoſſible. Seeds, and other ſuch things, are of ſome determinate growth; the ſize of which we know, and are well acquainted with their internal ſtructure, which is only a farinaceous matter contained in a thick ſuperficial ſkin or covering.

On the contrary, theſe foſſils, when examined, prove to be of various ſizes, from the minuteſt ſpeck viſible to the

eye, to near an inch in diameter, a size that no *lentil* could be ſuppoſed to arrive at. They are of two kinds; the one convex on both ſides, the other convex on one ſide only, and plane on the other. The firſt are thickeſt in the middle, and gradually leſſen in thickneſs all round, till they terminate in a thin edge; the others are juſt like the halves of theſe when ſplit horizontally. Thoſe which are convex on both ſides, have uſually ſeveral crooked lines, riſing from the umbilicus on each ſide, and tending toward the circumference; and the flat ones have uſually on the flatted ſide a number of concentric circles ſurrounding the umbilicus, and one another to the edge. When theſe are broken, they are found to conſiſt of a number of caſes, or coats, one within another, all of the ſame ſhape with the outer one; and ſome of them are ſtriated, or made up of tranſverſe fibres. They are plainly of animal origin, though they differ from all the parts of animals hitherto known. Woodward's Cat. of Foſſils, vol. ii.

Dr. Woodward, in one place, ſuppoſes them to have been the looſe bones which are found in the heads of ſome ſea-fiſhes, and are ſuppoſed to ſerve for hearing; but that they belong to ſome fiſh at preſent unknown, or that has not been yet examined in this particular: there is, however, another much more probable opinion, which he mentions afterwards, that they may have been opercula of ſhell-fiſhes, of the nature of the umbilicus Veneris, of which the fiſhes we know afford us a great variety; and the many others we are yet unacquainted with may furniſh numbers of other kinds very different from all we do know.

Theſe bodies are found in a hard greyiſh ſtone, and ſome of the large ones, which are flatted on one ſide, give great reaſon to judge that they are of this origin, as ſome of the large ones have on the flat ſide a reddiſh line, beginning at the centre, and thence continuing, in a ſpiral form for eleven or twelve turns, till it reaches the edge of the ſtone. This is exactly the formation and lineation of the common umbilicus Veneris, only that it has fewer ſpires. The ſtone, called by authors *lapis numiſmalis*, is generally allowed to be of the nature of theſe opercula, and this differs very little from theſe large *lentes lapideæ*, as they are called.

LENTIGO, a cutaneous diſorder, popularly called FRECKLES.

LENTIGO is alſo uſed, by Dr. Quincy, for a brown, ſcaly, or ſcurfy eruption upon the ſkin; ſuch, eſpecially, as is common to women in the time of child-bearing.

LENTIL, *lens*, in *Botany*, the name of a genus of plants, according to Tournefort, the characters of which are theſe: the flower is of the papilionaceous kind, and from the cup there ariſes a piſtil, which finally becomes a ſhort pod, containing orbicular ſeeds, and thicker toward the middle than at the edges.

In the Linnæan ſyſtem, this is a ſpecies of ERVUM.

The common *lentil*, or *ervum*, with compreſſed ſeeds, which are convex, is cultivated in many parts of England, either as fodder for cattle, or for the ſeeds, which are frequently uſed for meagre ſoups. This is an annual plant. It riſes with weak ſtalks a foot and a half high, garniſhed with winged leaves at each joint, compoſed of ſeveral pair of narrow lobes, terminated by a tendril or claſper, which faſtens to any neighbouring plant, and is thereby ſupported; the flowers come out in May upon ſhort foot-ſtalks from the ſide of the branches; they are ſmall, of a pale purple colour, and are ſucceeded by ſhort flat pods, containing two or three ſeeds, which are flat, round, and a little convex in the middle. The ſeeds of this plant are ſown in March on dry lands, and in April on wet land, and ripen in July: the uſual quantity allowed is from a buſhel and a half to two buſhels to an acre. If theſe are ſown in drills like peas, they will ſucceed better than when ſowed the common way; the drills ſhould be a foot and a half aſunder, to allow room for the Dutch hoe to clear the intervals.

Lentils make excellent ſweet fodder; and are therefore to be preferred to all other kinds for calves and other young cattle. They are likewiſe the beſt as well as cheapeſt food for pigeons.

The ſeeds of *lentils* are frequently the common food of the poor in ſome of the iſlands of the Archipelago, and other warm countries, when they can meet with no better fare.

Another ſort of *lentil* has of late years been cultivated in England, under the name of French *lentil*. This is the *lens major* of Caſpar Bauhine; and being twice the ſize of the common *lentil*, is by ſo much the better worth cultivating. This is called *tills* in many parts of England. Miller's Gard. Dict.

The ancients affirm that *lentils*, eaten with their ſkins on, bind the body, and ſtop a looſeneſs; and yet at the ſame time, that the liquor they are boiled in looſens the belly. They are but rarely uſed in phyſic, though the flour of them may be uſed outwardly in cataplaſms, for the ſame purpoſes as bean-flour.

LENTISCUS, the wood of an ever-green tree of the ſame name, of ſome uſe in phyſic: it is an aſtringent and fortifying, and is much uſed for tooth-picks. See MASTIC-*tree*.

It contains a kind of gum, or roſin, which is maſtic; the ſame with the incenſe of Perſia, ſo highly commended by Strabo.

The *lentiſcus* has nearly the ſame properties with the ſaunders; but it has more turpentine in it, and ſometimes paſſes by urine.

LENTISK, in *Botany*. See MASTIC-*tree*.

LENTISK, *African* and *Peruvian*. See *Indian* MASTIC.

LENTOR, in *Medicine*, a viſcidity or fizineſs.

A viſcid or fizy ſtate of the animal fluids is productive of many diſtempers. Thus, Boerhaave informs us, that a pinguious viſcidity, from vegetable aliment, is cauſed, firſt, by a diet of crude and unfermented farinaceous ſubſtance, and auſtere, immature vegetables. Secondly, by a defect of good blood; a ſufficient quantity of which is neceſſary to the aſſimilation of the aliment, and the converſion of their juices into good blood. Thirdly, by a debility of the veſſels and viſcera, or a defect and inactivity of the bile; which laſt is very powerful, when in a due ſtate and quantity, in attenuating viſcidities of alimentary ſubſtance. Fourthly, by a diminution of animal motion; for motion ſtrengthens the ſolids, attenuates the fluids, and promotes the due digeſtion and aſſimilation of the aliments. Fifthly, by a diſſipation of the moſt fluid parts of the blood, through the relaxed ſecerning veſſels; for it is evident, that when the moſt fluid parts are loſt, what remains muſt become more thick and viſcid. Hence the error of thoſe is obvious, who prepoſterouſly carry off the fineſt particles of the blood by enormous quantities of ſudorifics and diuretics. Sixthly, by the retention of the thicker parts of the fluids, on account of the debility of the excretory organs.

This viſcidity is originally formed in the firſt organs of digeſtion; from whence it is propagated to the blood, and the fluids thence derived; and when any of theſe viſcid particles paſs the lacteals, and get into the blood, their immediate effects are principally manifeſt in the lungs, where they cauſe a dyſpnœa, not being able to paſs readily through the ſmall veſſels thereof.

The effects of ſuch a viſcidity in the firſt organs of digeſtion are, an utter proſtration of appetite, ſometimes attended with the diſcharge of a viſcid ſubſtance, much reſembling frogs ſpawn; a ſenſe of repletion, naufea, and inclination to vomit; becauſe theſe acidities, adhering to the coats of the ſtomach, excite an uneaſy ſenſation, in the manner a feather does, when thruſt down the throat; and a crudity of the aliments taken in, becauſe they cannot be digeſted.

Hence, likewiſe, the bile is rendered inert and inactive, being, as it were, inviſcated by theſe viſcidities, and carried along with them through the inteſtinal tube, and loſt. Hence, alſo, ariſe pituitous, and, as it were, vitreous concretions of the ſtomach and inteſtinal tube, which are productive of exceſſive pains, when adhering to the coats of theſe organs. Coſtiveneſs, and tumors of the belly, are moreover excited, for want of a proper ſtimulus from the bile, and a retention of the groſs viſcid feces: this is frequent in children. Hence, alſo, a due preparation, perfection, and ſecretion of the chyle, is prevented. In the blood, fizineſs, patinch, and immeaſibility, are generated; in the veſſels, obſtructions and concretions: hence, alſo, pale and inſipid urine, viſcid ſaliva, and leucophlegmatic tumors. The due ſecretions are likewiſe prevented; and the more ſubtile parts of the fluids become deficient; whence a coalition of the ſmalleſt canals is induced.

With reſpect to the cure, it is to be performed, firſt, by a conſtant uſe of aliments and drink well fermented, and duly ſeaſoned with attenuating ſalts and aromatics; for fermentation deſtroys the viſcidity of all the farinaceous vegetables. Rice or oats, boiled, make a kind of jelly or glue, which is deſtroyed by fermentation. Beer well fermented does not cauſe phlegm, but ptiſans will: therefore in cold ſanguine diſeaſes ſtrong beer is proper; and in hot, inflammatory diſorders, ptiſans. Secondly, by broths made of animals abounding with exalted volatile ſalts; and theſe broths muſt be ſeaſoned with acrid vegetables. Thirdly, by ſtrengthening the veſſels and viſcera. Fourthly, by exerciſe and motion; for without a due degree of theſe, nothing can relieve, much leſs cure. Fifthly, by diluting, reſolvent, ſtimulating, biſſous, and ſaponaceous medicines. James, Med. Dict.

LEO, *Leon*, the fifth of the twelve ſigns of the zodiac.

The ſtars in the conſtellation *Leo* in Ptolemy's Catalogue are 27, beſides the informes, which are 8, in Tycho's

30, in the Britannic Catalogue 95; the names, places, longitudes, latitudes, and magnitudes whereof, are as follow.

LEO, in *Botany*, a name used by some authors for the COLUMBINE, or *aquilegia*. Columella, beside others, calls it by this name.

LEO, the *lion*, in *Zoology*. See LION.

LEO *pulex*, a name given by Mr. Reaumur to a species of insects, which feeds on the *pulex arborens*, or common tree-puceron, in the same manner that the creature called the *formica leo* does on the ants: this being also, like that, an animal, yet in an imperfect state, and finally to be changed into a different creature. This author has kept up the remembrance of this analogy between them, by giving this a similar name.

The *leo pulex* is usually bred among the herds of the pulices, which he devours most unmercifully. He is a worm of the hexapode, or six-legged kind, and very soon arrives at the time of his change; after which he becomes a green fly with four wings. Another animal of this kind, and not less destructive of this small race of animals, is a six legged worm of a whitish colour, and smaller than the former, which finally becomes a round-bodied beetle. Another species of these devourers this author calls *vermis hystrix*, the porcupine-worm, from the vast number of spicula, or tender prickles, with which he is armed. This also finally becomes a round and small beetle. Reaumur, Hist. insect. tom. i. See LION *Puceron*.

LEOCROCOTTA, in *Natural History*, a name given by the ancients to an animal, said to be the swiftest of all creatures in the world. It is described as a mongrel or bastard animal, unable to propagate its own species, being begotten upon the bitches by the male hyæna of some of the larger kinds: but is one of those animals, the existence of which is much to be doubted. The Latin authors have made some confusion between this creature and the MANTICHORA, attributing the things that have been said of one to the other.

LEONINE, in *Poetry*, is applied to a kind of verses which rhyme at every hemistich, the middle always chiming to the end.

In this kind of verse we find several ancient hymns, epigrams, prophecies, &c. For instance; Muretus, speaking of the poetry of Lorenzo Gambara of Bresse, says,

Brixia conspirates, quæ condunt carmina vates
Non sunt nostrates tergere digna nates.

The following one is from the school of Salernum:

Ut vites pœnam, de potibus incipe cœnam.

The origin of the word is somewhat obscure: Pasquier derives it from one Leoninus, or Leonius, who excelled in this way, and dedicated several pieces to pope Alexander III. others derive it from pope Leo; and others, from the beast called *lion*, because it is the loftiest of all verses.

M. Fauchet makes the *leonine* rhyme the same with what the French call the *rich*, and we the *double rhyme*, i. e. where two syllables have the same orthography, accentuation, and pronunciation, with two others.

LEONTESERES, in the *Natural History of the Ancients*, the name of a species of agate, famous in early times for its imaginary virtues in taming the rage of wild beasts, and not a little esteemed among us for its beauty. It is the most variegated of all the agates. Its ground colour is yellow, and its variegations are flame coloured, white, black, and green.

Sometimes it is one irregular congeries of all these colours, but more frequently it is very beautifully variegated with them in form of clouds and veins; the black and green particularly are usually disposed in concentric circles round one or more points. It is found only in the East Indies, and is very scarce. Hill's Hist. of Foss. p. 487.

LEONTIASIS, a name used by some authors for the ELEPHANTIASIS.

LEONTICA, feasts or sacrifices celebrated, among the ancients, in honour of the sun.

They were called *Leontica*, and the priests who officiated at them *Leontes*, because they represented the sun under the figure of a lion radiant, bearing a tiara, and griping in his two fore-paws the horns of a bull, who struggled with him, in vain, to disengage himself.

The critics are extremely divided about this feast: some will have it anniversary, and to have made its return not in a solar, but in a lunar year; but others hold its return more frequent, and give instances where the period was not above two hundred and twenty days.

The ceremony was sometimes also called *Mithriaca*; Mithras being the name of the sun among the ancient Persians.

There was always a man sacrificed at these feasts, till the time of Hadrian, who prohibited it by a law. Commodus introduced the custom afresh, after whose time it was again exploded.

LEONTICE, in *Botany*, the name given by Linnæus to that genus of plants which Tournefort and others have called LEONTOPETALON.

LEONTICE is also a plant mentioned by the ancient Greeks, and called by them CACALIA.

Dioscorides tells us it had these names in common, and that it was of great virtue in curing diseases of the *aspera arteria*, or wind-pipe.

This medicinal plant of the Greeks was very different from that we now call CACALIA. Some have described it to have flowers like the oak, others like the olive tree, but the old manuscripts of Dioscorides all say, the flowers were like those of bryony. Hence it could by no means be the *cacalia* of the moderns; nor is it easy to say, from such short and uncertain accounts, what it was.

LEONTODERON, in *Natural History*, a name given by several authors to a species of agate, of a plain yellowish colour, without variegations.

LEONTODON, in *Botany*. See DANDELION.

LEONTOPETALOIDES, in *Botany*, the name of a genus of plants described by Dr. Ammian, being a species of the *leontice* of Linnæus. The characters of which are these: the flower is monopetalous, of the funnel-fashioned kind, and divided into several segments at the edge: this is succeeded by a bladder, or inflated fruit, which contains a number of oval seeds.

The plant is a native of the East Indies; its root is tuberose, and two inches thick in the middle: it is grey on the outside, and white within, and sends out but few fibres. There usually arise four stalks from each root; these are very tall, and of a finger's thickness; two of them usually bear each one large and beautiful leaf, very thin in its substance, variously jagged, and of a beautiful green. The two others bear each a tuft of flowers, which are large and yellow, and stand in cups of a fine green, composed each of one leaf, divided into some segments at the end: each flower is sustained on a pedicle of about an inch in length; these are succeeded by the fruit, which are green inflated bladders of an angular form, and of an inch diameter in the largest part, from whence they run to a point, where they are purple. The seeds are large, striated, and of a pale brick-colour. Act. Petrop. vol. viii. p. 209.

LEONTOPETALON, in *Botany*, the name of a genus of plants, called *leontice*, by Linnæus. See LION's *leaf*.

The *artanita*, or *leontopetalon*, of the ancients, is generally esteemed a synonymous name for the *cyclamen*, or SOW-*bread*, and is used as such by most authors; but if the Arabian writers are understood of it in this sense, it will be hard to reconcile their works with those of the Greeks on the subject of this plant.

LEONTOPODIUM, *lion's* foot, in *Botany*, a name given by some to a genus of plants, otherwise called *gnaphalium*. See CUD-*weed*.

LEONURUS, in *Botany*. See LION's *tail*.

LEOPARD, in *Zoology*, the English name of the long-tailed *felis*; a beast of prey, with the spots on the back and sides round, the lower ones variegated. It is a very nimble as well as fierce animal, so that scarcely any thing escapes it. Authors call the male PARDUS, and the female PANTHERA.

This creature, when carefully examined, is found to be very like a cat; particularly its head, teeth, tongue, feet, and claws. Its actions also are all like a cat's; it boxes with its fore-feet, as a cat does her kittens; leaps at its prey as the cat does; and will spit much in the same manner.

All the *leopard* kind as they walk, keep the claws of their fore-feet turned up from the ground, and sheathed, as it were in the skin of the toes, whereby they preserve them sharp for seizing their prey.

Notwithstanding the natural fierceness of the *leopard*, numbers of them are bred up tame, and kept for the Great Cham of Tartary's use, for the hunting of deer and other beasts.

They are most numerous in Africa and Syria.

The *leopard* of Buffon has its hair of a lively yellow colour; it is marked on the back and sides with small spots, disposed in circles and pretty close together; the face and legs are marked with single spots; the breast and belly are covered with longer hairs than the rest of the body, of a whitish colour; the spots on the tail are large and oblong: the length of this species, from nose to tail, is four feet, and that of the tail is 28 feet. This animal inhabits Senegal and Guinea, and spares neither man nor beast. The PANTHER destroys numbers of them: the negro women make collars of their teeth, to which they ascribe certain virtues. These animals are taken by the negroes in pit-falls, covered at the top with slight hurdles, on which they place a bait of flesh. The flesh is white and well-tasted, and eaten by them. The skins are valuable, and brought to Europe.

The leſſer *leopard*, kept a few years ago in the Tower, inhabits the Eaſt Indies; it has its face ſpotted with black; the ſkin white, and a large black ſpot on each ſide of the upper lip; the breaſt white, ſpotted with black; the back, ſides, and rump covered with hair of a bright yellow colour: the ſpots reſemble thoſe of the former, but are ſmaller; and the tail is ſhorter, tapering to a point, covered with ſhort hair.

The *hunting leopard* of India has a ſmall head, with the tip of the noſe black, and from each corner of the mouth to that of the eye, a duſky line; the ears are ſhort and tawny, and marked with a brown bar; the face, chin, and throat, are of a pale yellowiſh brown; the body of a light tawny brown, marked with many ſmall, round, black ſpots: the hair on the top of the neck is longer than the reſt; that on the belly white and very long: the tail is longer than the body, of a reddiſh brown colour, marked above with large black ſpots. This animal is of the ſize of a greyhound, of a long make, narrow cheſt and very long legs. It is tamed and trained for the chace of antelopes, which it overtakes by its rapidity. Pennant.

LEOPARD'S *bane*, *doronicum*, in *Botany*, a genus of the *ſyngeneſia polygamia ſuperflua* claſs. It has a flower compoſed of ſeveral hermaphrodite florets, which form the diſk, and female florets which compoſe the rays; theſe are included in one common empalement which has a double ſeries of leaves as long as the rays: in the bottom of the hermaphrodite florets is ſituated the germen, which becomes a ſingle, oval, compreſſed ſeed, crowned with hairy down: the female florets are formed like a tongue, and compoſe the border; theſe have a germen crowned by two reflex ſtigmas, but have no ſtamina; the germen becomes a ſingle furrowed ſeed without down. Miller enumerates four ſpecies, natives of Hungary and the Helvetian mountains, and of the Alps and Pyrenees.

The root has been ſometimes uſed in medicine; ſome have commended it as an expeller of the poiſon of ſcorpions; while others reckon it a poiſon itſelf; and affirm that it will deſtroy wolves and dogs. See DORONICUM.

LEPA, in our *Old Writers*, a meaſure which contained the third part of two buſhels. Whence we derive a *ſeed leap*.

LEPAS, in *Natural Hiſtory*, the name of a genus of ſhell-fiſh, the ſame as PATELLA, in the Linnæan ſyſtem is a genus of the teſtaceous worms, comprehending ten different ſpecies: its animal is the Triton; and the ſhell is multivalve, unequal, and fixed by a ſtem. The common Engliſh BARNACLE is of this genus.

LEPASTRUM, in *Natural Hiſtory*, the name of a genus of foſſils, of the claſs of the SELENITÆ, compoſed of filaments arranged into broad plates, and thoſe diſpoſed in the form of a radiated ſtar.

The word is derived from the Greek λεπις, *a ſcale* or *plate*, and αστρ, *a ſtar*.

Of this genus there are two known ſpecies; the one a bright browniſh white kind, with thinner flakes, the other a white dull-looking kind, with thick flakes. They are both found on the ſhores of Sheppey iſland in Kent, and form themſelves in the cavities of the ſeptariæ called by authors *ludus Helmontii*; and the ſeptariæ with theſe aſſixed to them, have been accounted a ſeparate ſpecies of that body, and called the *ſtarred waved coin*, or *ludus Helmontii ſtellatus*. The world in general has erred as to the origin of theſe beautiful foſſils, they having been ſuppoſed to be talcky ſpars; whereas their want of elaſticity, the great character of tale, and their not fermenting with acids, which is the fundamental diſtinction of the ſpars, prove them to be not at all of the nature of either of theſe bodies; and experiments on them plainly ſhew them to be a *ſelenites* of a particular kind. Hill's Hiſt. of Foſſ. p. 179. 148.

LEPERS. See ELEPHANTIASIS, and LEPROSY.

LEPIDIUM. See DITTANDER.

LEPIDOCARPODENDRON, a name given by Boerhaave to a genus of plants, called by Linnæus LEUCADENDRON.

LEPIDOIDES, Αεπιδοειδης, formed of λεπις, *ſcale*; and ειδος, *form*, *figure*, or LEPIDOIDES, in *Anatomy*, a name of the ſquamous or ſcaly ſuture of the CRANIUM.

LEPIDOPTERA, from λεπις, *a ſcale*, and πτερον, *wing*, in the *Linnæan Syſtem*, an order of INSECTA, with four wings, imbricated with ſcales; in the mouth is contained a ſpiral tongue, and the body is hairy. This order comprehends three genera, viz. the papilio or butterfly, the ſphinx, and the phalæna or moth; and each genus includes a number of ſpecies.

LEPIDOTES, in *Natural Hiſtory*, the name of a ſtone bearing a reſemblance to the ſcales of fiſhes. The word has been uſed by ſome, as the name of thoſe ſtones which are compoſed of ſmall flakes, or ſcales of tale, and by others to expreſs the ſtones containing fiſh, or the impreſſions of fiſh, found in many parts of Germany.

LEPISMA, in *Natural Hiſtory*, a genus of the *apterous* order of inſects; with ſix feet formed for running, a mouth having two ſetaceous palpi or feelers, and two rounded at their extremity, a ſetoſe tail, and a body covered with ſcales. This genus includes three ſpecies.

LEPIUM, in *Natural Hiſtory*, the name of a genus of foſſils of the claſs of the GYPSUMS; the characters of which are, that the bodies of it are moderately hard, compoſed of very ſmall particles, and of a duſky hue.

It is found in great plenty in Germany, and is one of the many ſubſtances which, from their uſe in faſing and caſting, the Germans call *ſpaad*. We have it in great plenty in Derbyſhire, and it is burnt into a ſort of plaiſter of Paris for the coarſer works; but it calcines very ſlowly and unequally. Hill's Hiſt. of Foſſ. p. 114.

LEPORARIA *aquila*, a name given by ſome authors to the *melanaëtos*, or *black* EAGLE, from his deſtroying great numbers of hares.

LEPORINUM *genus*, in *Zoology*, the name of a genus of animals, ſo called from their general reſemblance to the hare in ſhape, and other particulars; the characters by which they are diſtinguiſhed from other quadrupeds are theſe: they have feet divided into claws; they feed on vegetables; and they have two very long teeth in the forepart of their mouths. Ray's Syn. Quad. p. 204.

LEPRAS, in *Zoology*, the name of a ſea-fiſh of the TURDUS, or wraſſe-kind, remarkable for the great variety and beauty of its colouring. It is ſeldom caught of more than five or ſix inches in length, and is conſiderably broad and flat. It ſometimes grows to a foot long, but that only in the ocean, never in the Mediterranean Sea, where it is uſually caught; and even there very rarely. It is ſpotted all over like the body of a leopard. It is one of the moſt beautiful fiſh of the Mediterranean, but is not much eſteemed at table, being of an inſipid and watery taſte.

LEPROSO *amovendo*, in *Law*, an ancient writ that lay to remove a *leper*, or *lazar*, who thruſt himſelf into the company of his neighbours in any pariſh, either in the church or at other public meetings, to their annoyance. The writ lies againſt thoſe *lepers* that appear outwardly to be ſuch, by ſores on their bodies, ſmell, &c. and not againſt others: and if a man be a *leper*, and keep within his houſe, ſo as not to converſe with his neighbours, he ſhall not be removed.

LEPROSY, LEPRA, in *Medicine*, a foul, cutaneous diſeaſe, appearing in dry, white, thin, ſcurfy ſcabs, either over the whole body, or only ſome part of it; and uſually attended with a vehement itching, and other pains.

The word is derived from the Greek λεπρα, which ſignifies the ſame; and that from λεπις, *ſquamma*, *ſcale*.

The *leproſy* ſeems to ariſe from a great obſtruction of perſpiration, and a faulty ſerum; whereby the thin ſaline humours are thrown off from the blood, and detained by the denſity and cloſeneſs of the cuticula.

Hoffman thinks the ſeat of the various kinds of *leproſy* to be chiefly the fatty membrane of the ſkin, where the ſomes of the corrupt matter principally reſides; inſomuch that by corroding and inflaming the nervous fibrillæ of the ſkin, various kinds of puſtules are generated. In warm countries the *leproſy* was very infectious, but it does not appear to have been the caſe, at leaſt in the ſame degree, in colder climates. It is an hereditary diſeaſe, and has been ſometimes occaſioned by exceſſive terror, two inſtances of which occur in the Med. Obſ. vol. i. art. 18. The remoter cauſes are whatever diminiſh the vital heat and reduce the general ſtrength of the body.

This diſtemper has been much more frequent in former times than it is at preſent, and much more in the hot countries of the Eaſt, particularly among the Jews, than among us: perhaps becauſe the ſalts, which, by the appointment of nature, are to be eliminated through the pores of the ſkin, along with the recrementitious ſerum their proper vehicle, are, in hot countries, conveyed in greater plenty to the ſurface of the body, than in theſe northern regions they ordinarily are; and, ſticking in their paſſage in the thin dry membrane of the cuticle, the aqueous parts, which are their vehicle, flip away from them by inſenſible evaporation, and leave them there to corrode and fret it, till at length, through the quantity ſo gathered, the membrane becomes dry, brittle, and white, which is the cauſe of that defquammation, or falling away in white ſcales; that whiteneſs, as well as the brittleneſs, proceeding merely from the quantity of theſe ſalts, which are themſelves white; and when the moiſture is drawn from them, being aculeated, and having inſinuated themſelves into the pores of the cuticle, they diſſolve the continuity of it by their points and edges; which thus mortified and broken, is apt, on the leaſt friction, to fall off, as above mentioned.

The ancients diſtinguiſhed two kinds of *leproſy*, viz. the

lepra Græcorum, and *lepra Arabum*: though the two seem only to have differed in degree; the symptoms of the Grecian being farther heightened and aggravated in the Arabian.

Lucretius supposes the elephantiasis to be generated in Egypt, and no where else; but if the *leprosy* of the Jews is the same as that of the Negroes, which is highly probable, then it may be affirmed, that it is endemial to the southern and inland parts of Africa.

That it was contagious all histories, sacred and prophane, agree. Pliny acquaints us, that it did not invade Italy till the time of Pompey the Great, and that it was brought from Egypt, and is peculiar to that kingdom. Some have thought that the *leprosy* of the Arabians, or more properly of the Africans, was the parent of the lues venerea: however that be, it is certain, that since the pox has been curable, the elephantiasis seems to have disappeared, and the *leprosy* of the Greeks has been much less frequent than before.

In the West Indies this disorder is known by the name of the black SCURVY. Its approach is observed to be gradual; at first there are many spots of a yellow-brown cast, which soon turn purple, and of a copper colour; these increase and become thick and rough, with hard scales; a numbness is felt on the fingers and toes; the breath is fetid, the voice hoarse, the hard and scaly parts crack, and ulcers appear in different parts; but at length a fever comes on, which terminates in death.

An inveterate *leprosy* was judged to be absolutely incurable; but Aretæus says, when the disease is new and recent, there are great hopes of a cure. What he and Celsus prescribe in order to the cure is not worth repeating; for if any medicines will do, they must be of the Herculean kind. Authors are excessive in the praise of viper's flesh, which Hoffman judges to be quite insignificant. Joel advises bleeding, and purging with twelve grains of the extract of black hellebore, or three grains of the glass of antimony, in conserve of roses: but the vitrum ceratum is more safe, and may be given in a larger dose. Towne confesses, that the antimonial preparations yielded most relief in Barbadoes, but he could not say that they perfected the cure. On the other hand, mercury exasperated the distemper, irritated the ulcers, and made them spread the faster.

The impetigo or *leprosy* of the Greeks, begins with red pimples or pustules breaking out in various parts of the body; sometimes they appear single, sometimes a great number arise together, especially on the arms and legs. As the disease increases, fresh pimples arise, which joining the former, make a sort of cluster, all which enlarge their borders, and spread in an orbicular form. This *leprosy*, according to Turner, breaks out first in the elbows and knees, but soon spreads farther, and gradually shews itself over the whole body. The causes and seat of this disease are said to be the same as the former. Willis blames all dried and salted meats, especially hog's flesh, and fish, particularly shell-fish; because the poor people in Cornwall inhabiting near the sea-coast, were formerly much subject to leprous diseases, and had many hospitals erected on that account.

In the method of cure, says Hoffman, we should endeavour to discharge out of the body, the mass of corrupt glutinous and acrid humours, by sufficient bleeding, and abstinence, by purges, as well gentle as drastic; then by proper aliment, and a good regimen, promote the generation of wholesome juices; and likewise by external, deterfive, consolidating and drying remedies, to free the part from pain, tumors, itching, and ulcers. The purges may consist of the root and the resin of jalap, the extract of black hellebore, elaterium mixt with calomel, or æthiops mineral, and gum ammoniac. Among those things which stimulate the parts to an excretory motion, and more powerfully melt down the tenacious humours, the wood and bark of guaiacum exceed all others: the most considerable besides these, are the tartarized and acrid tincture of antimony, sulphur of antimony, cinnabar, and, if a venereal taint is suspected, a decoction of crude antimony; which medicines in a convenient dose in the morning, with purifying decoctions drank in bed, afford great relief. But if these fail, recourse must be had to mercury, which some, after extinction, mix with flowers of sulphur and camphor, and rub it on the joints to promote a salivation. Others more properly give mercurius dulcis, with double the quantity of crabs-eyes, and calx of antimony, rising gradually from three or four grains, to a scruple, in order to salivate with proper precautions.

The lesser degrees of *leprosy*, says Sir John Pringle, in his Obs. on Diseases of the Army, p. 306, are frequently confounded with the scurvy, and even itch; from which, however, it may be distinguished by the hardness of the skin in one or more parts of the body, attended with a dry scurf, sometimes oozing pustules, or dry scabs, and always with some degree of itching; whereas the true scorbutic spots are of a livid colour, not commonly scurfy or raised above the skin, and are attended with manifest signs of a lax state of the fibres, and corruption of the blood. For a real scurvy imports a flow, but general resolution or putrefaction of the whole frame; whereas the scabies, impetigo, or *leprosy*, may be found to affect those of a very different constitution.

This disorder is so far from being curable by externals only, that it is sometimes dangerous to attempt to remove the scurfs of *leprous* people in that manner. On the contrary, it is necessary to change the humours, by a spare diet, exercise, alterative mercurials, or frequent purges of the saline kind. Ibid.

Dr. Mead recommends the tincture of cantharides in this distemper.

Dr. Lysons has met with great success in the use of the following decoction, viz. R cort. interior. ulmi rec. ℥ iv. coq. in aq. pur. ℔ iv. ad ℔ ij colatur. cap. ℔ ß. one; continued for several weeks. If after using it, the efflorescences increase, the symptom is favourable.

Others have advised the same general course of diet and medicine for the cure of the leprosy as the scurvy. This distemper, which was so common in our country long ago, appears very seldom at present; which may be owing to the inhabitants of Britain eating more vegetable food than formerly, living more upon tea and other diluting diet, using less salted meat, being more cleanly, better lodged and cloathed, &c.

Lepra Arabum, is the same with what is otherwise called *elephantiasis*, because in this the patient's skin is rough and wrinkled like an elephant's hide. See ELEPHANTIASIS.

LEPTODECARHOMBUS, in *Natural History*, the name of a genus of fossils of the class of the SELENITÆ.

The word is derived from λεπτος, *thin, slender, fine*, and ῥομβος, *a rhomboid figure*, and expresses a thin or slender rhomboidal body, consisting of ten planes or sides, each of which is so nearly equal to that opposite to it, as very much to approach a decahedral parallelopiped; but as the broader and flatter planes, which form the top and bottom in this genus are not regularly equal to each other, so neither are the eight narrower to their opposites; but they usually differ in breadth, and in the angles they make. Of this genus there are five species enumerated by Dr. Hill in his Hist. of Fossils, p. 128 to 129.

LEPTOS *libanotis*, in the *Materia Medica of the Ancients*, a name given by some of the Greek writers to the small frankincense, that is such as came to their hands in small flakes, broken from the larger masses in the gathering or packing up. This was also called *manna thuris*, the manna of frankincense, the word *manna* being of old used to express any thing formed of granules, or small pieces. The ancients esteemed this *leptos libanotis*, or *manna thuris*, when pure, beyond any other kind, for they always valued that frankincense most, which was driest and most brittle. and such only as was so, could break off in these small flakes. The medicine, however, soon grew subject to adulteration, and lost its credit; for the dust of the frankincense being allowed to be put up among this *manna thuris*, Dioscorides tells us, that in his time people, greedy of gain, had found the way to adulterate it, by adding, instead of this genuine dust, the sifted powder of the resin of the pine-tree.

LEPTUM, in *Antiquity*, a small piece of money, which, according to some, was only the eighth part of an obolus; but others will have it to be a silver or brass drachm.

LEPTURA, in the *History of Insects*, the name of a genus of four-winged flies, the antennæ of which are oblong, slender, and setaceous; the exterior wings are truncated at their extremity, and the thorax is of a subcylindric figure.

This genus in the Linnæan system belongs to the order of *coleoptera*, and comprehends twenty-five species.

These flies have been, by the generality of authors, reckoned among the beetles. See SCARABÆUS.

LEPTURUS, The name is of Greek origin, and is formed of λεπτος, *slender*, and ουρα, *a tail*, expressing that the fish bearing this name has a very long and slender tail.

LEPUS, in *Zoology*. See HARE.

LEPUS, the *Hare*, in *Astronomy*, a constellation of the southern hemisphere; whose stars in Ptolemy's catalogue are twelve; in that of Tycho thirteen; in the Britannic catalogue nineteen; the names, places, longitudes, latitudes, and magnitudes whereof are as follow:

Names

LEPUS *aquaticus*, the *water-hare*, a name given to the crested DIVER, or colymbus of America, which is the same species with the larger European kind, though described by many authors as a different bird. It has the name of the *sea-hare* or *water-hare*, from its great nimbleness in the water. It is caught with much difficulty; and the Mexicans have a thousand fabulous stories about it.

LE ROY *le veut*, a form of words, by which the royal assent is signified by the clerk of the parliament to public bills; to private bills this assent is expressed by *soit fait comme il est desiré*.

LE ROY *s'avisera*. By these words to a bill, presented to the king by his parliament, is understood his absolute denial of that bill in a more civil way; and the bill thereby becomes wholly null and void. See ROYAL and PARLIAMENT.

LESBIAN *Cymatium*. See CYMATIUM.

LESBIUM *marmor*, a name given by the ancients to a species of marble of a bluish-white, sometimes used for the vases and other ornamental works, but principally in the walls of public buildings.

LESSEES, a term used by sportsmen for the dung of a wild boar.

LESSON, in the *Manege*, is used for any piece of instruction in that art, whether given to the scholar or the horse.

LESSON, among *Ecclesiastical Writers*, portions of the holy scripture, read in Christian churches, at the time of divine service.

In the ancient church, reading the scriptures was one part of the service of the catechumens, at which all persons were allowed to be present, in order to obtain instruction.

The church of England, in the choice of *lessons*, proceeds as follows; for the first *lesson* on ordinary days, she directs, to begin at the beginning of the year with Genesis, and so continue on, till the books of the Old Testament are read over, only omitting the Chronicles, which are for the most part the same with the books of Samuel and Kings, and other particular chapters in other books, either because they contain names of persons, places, or other matters less profitable to ordinary readers.

The course of the first *lessons* for Sundays is regulated after a different manner. From Advent to Septuagesima Sunday, some particular chapters of Isaiah are appointed to be read, because that book contains the clearest prophecies concerning Christ. Upon Septuagesima Sunday Genesis is begun, because that book, which treats of the fall of man, and the severe judgment of God inflicted on the world for sin, best suits with a time of repentance and mortification. After Genesis, follow chapters out of the books of the Old Testament, as they lie in order; only on festival Sundays, such as Easter, Whitsunday, &c. the particular history relating to that day is appointed to be read; and on the Saints days, the church appoints *lessons* out of the moral books, such as Proverbs, Ecclesiastes, Ecclesiasticus, &c. as containing excellent instructions for the conduct of life.

As to the second *lessons*, the church observes the same course both on Sundays and week days: reading the gospels and Acts of the Apostles in the morning, and the epistles in the evening, in the order they stand in the New Testament: excepting on saints-days and holy-days, when such *lessons* are appointed, as either explain the mystery, relate the history, or apply the example to us.

LESSON and LESSEE. See LEASE.

LET-*fall*, in *Sea Language*, the word of command for putting out a sail, when the yards are aloft, and the sail is to come down from the yard; but when the yards are stricken down, then the sail is loosed below, before they hoist the yard.

Let fall is not properly said of top-sails, because they lie on the top; and therefore the word for them is, *Heave out your top-sails*. Nor can it be applied to the mizzen; for the word is, *Strike the mizzen and set it*. So that in strictness the term *let-fall* belongs only to the main-sail, fore-sail, and sprit-sail, when their yards are hoisted up aloft.

To LET-*in*, among *Shipwrights*, is to fix a diminished part of one plank or piece of timber into a vacancy, formed in another for this purpose. See RABBETING.

LETHARGY, *Αηθαργια*, in *Medicine*, from *λαθω*, *oblivion*, and *αργια*, *slowness*, *laziness*, a disease consisting of a profound drowsiness or sleepiness, from which the patient can scarce be awaked; or, if awaked, he remains stupid, without sense or memory, and presently sinks again into his former sleep. See COMA.

The *lethargy* is usually accompanied with a fever and delirium. Boerhaave makes the *lethargy* a gentle APOPLEXY arising from the same causes, and to be known and cured in the same manner.

Some authors distinguish the *lethargy* from the CARUS, because this latter is without a fever, or at most is preceded with a violent one; whereas the *lethargy* is attended with a slow one, manifested by the frequency of the pulse, and a less frequent and febrile respiration. Celsus ranges the *lethargy* in the number of acute diseases, the patient usually dying on the seventh day. A *lethargy* frequently succeeds a frenzy. It does not invade so suddenly as an apoplexy, nor kill so soon: the worst symptoms attending it are a tremor of the limbs, and a cold sweat of the face.

From physiology, we learn, that natural sleep depends upon a more diminished and more languid influx of the nervous fluid into the nerves destined to sensation and voluntary motions; and that this languid influx is partly owing to a want of nervous fluid, partly to the slow circulation of the blood through the vessels of the brain, and membranes. It follows, that the immediate cause of sleepy affections is a very languid and diminished influx of the nervous fluid, from the cortical substance of the brain, into its medulla; and from thence into the nerves destined to sense and motion. The causes of the preternatural impediments of this influx seem principally three; first, either a too great want of the fluid itself; or secondly, a laxity of the tubes which convey it; or lastly, a pressure upon the cortical substance of the brain; and this arises either from the blood passing slowly through the brain, and the meninges thereof, or absolutely stagnating, or some foreign matter incumbent on the said cortical substance, by which the medulla, every where joined to the cortex, is pressed together, and, consequently, cannot receive a sufficient quantity of the fluid. The remote causes of these diseases are whatever diminishes the vis vitæ or obstructs its influence; as tumors pressing on the brain or turgescency of the vessels, from obstructed menses, hæmorrhoids, long absence of the gout, &c. a too free use of spirituous liquors, offensive vapours, blows on the head, &c.

A physician, in the cure of sleepy diseases, should regard these three intentions; first to rouse the patient from his sleep; next to remove the difficulty of circulation, the stagnation or extravasation of the blood or serum in the head; and thirdly, to restore the lost strength of the membranes and vessels of the brain.

For shaking off drowsiness, and awaking the patient, those remedies are efficacious which act upon the nervous parts, by agitating them, vellicating and inducing a tremulous and oscillatory motion through the whole nervous system: such are 1. Powerful acids; and of these the preference must be given to the spirit of vendigrise, which is nothing but a most concentred spirit of vinegar, mixed with the essence of castor: this applied to the nose, in stimulating and penetrating, is superior to all others. 2. Volatile salts, as urinous spirit of sal ammoniac prepared with quick lime; which being applied to the vertex, or, what is still better, put into the nose, excites sternutation, and greatly shakes off the torpor and drowsiness. 3. Foetid things, as galbanum, partridge-feathers, and others burnt, so that the strong scent may affect the nose. 4. Cold water suddenly poured all over the head, which, by strengthening at the same time the membranes of the brain, readily dispels sleep. 5. Cataplasms prepared of strong vinegar, rue, bay leaves, tops of savory, mustard-seed, castor, and camphor, applied to the head, when shaved, the forehead, and the temples. The efficacy of these is promoted, and, at the same time, the serous colluvies, if it is offensive, is derived from the head, by sternutatories; the best of which is salt of white

white vitriol, if ten grains of it are diſſolved in half an ounce of majoram water, and drawn up the noſe; by veſicatories of cantharides, ſomewhat large, and laid on the feet and neck; for theſe both give motion to the ſolid nervous parts, and make a revulſion of the ſerous humours; by cupping-glaſſes, either with or without ſcarification. 4. By ſtrong frictions of the inferior parts. 5. By acrid and ſtimulating glyſters, which are in ſuch caſes, of very great ſervice, to which ſal gemmæ, common ſalt, or the roots of ſcuills are added, with a view of increaſing the ſtimulation.

The patient, by the help of theſe, being rouſed from his drowſineſs, it remains, that an equal circulation of the humours through the whole body be reſtored, and then the debilitated parts ſtrengthened. The firſt end is anſwered by frequent bleeding, whilſt the ſleepineſs laſts, if the veſſels are turgid with blood; and much more ſhould it be performed, when the ſleepineſs is conquered, in order to prevent a relapſe; then likewiſe if the firſt paſſages are loaded with excrements, or ſeized with ſpaſms, the body ought to be opened with a gentle laxative. Nervous, mixed with diaphoretic medicines, contribute to diſperſe ſtagnations of the humours, and alſo to ſtrengthen the infirm parts; among theſe the eſſence of aloes-wood and amber, with the ſpirit of lilies of the valley, of ſal ammoniac, and acrid tincture of antimony, are of great efficacy, and ſalt of hartſhorn, with ſalt of amber, cinnamon of antimony, and be toardic mineral in the form of a powder, have very great and ſalutary effects.

Laſtly, relapſes into ſleepy diſorders may be prevented partly by a removal of the cauſes producing them; and ſince a ſuppreſſion of the ſanguine excretions, or habitual arthritic paroxyſms, contribute very much to the generation of thoſe diſorders, he will not do amiſs who endeavours to recall theſe fluxes and pains, and preſerve a regular ſucceſſion of them. In diet, idleneſs, drunkenneſs, meats difficult of digeſtion, and ſpirituous things, muſt be avoided; let the body be exerciſed carefully; all repletion is to be avoided; and faſting, and eating ſparingly, is of uſe: the patient muſt entirely abſtain from fiſh, milk, and cheeſe; and among fruits, all that are watery muſt be abſtained from; he muſt eat more roaſted than boiled fleſh. Bread muſt be entirely cleanſed of the darnel, with which it is often intermixed. Let old infirm men uſe wine, as their milk: let them not protract their ſleep too long; let them be cautious of affections of the mind; let them frequently enjoy the converſation of their friends; let them amuſe themſelves with convenient journeys; let them take care to preſerve the excretions, as well by ſtool, as by the pores of the ſkin; and let them not forget the uſual bleedings at their ſtated times. In every ſleepy diſorder it is proper to avoid warm baths, vaporous ſubſtances, and ſuch as ſwelling, by their fragrant and ſtrong ſmell, to ſleep. Much more abſurd it is to uſe narcotics, ſulphureous remedies, opiates, or medicines in which ſaffron or poppies are ingredients; to this claſs belong theriacal medicines which the ancients uſed to preſcribe in theſe affections; for this is adding fuel to the fire.

We muſt above all thing take care not to uſe ſternutatories in the beginning of this diſorder, to rouſe the patient from ſleep, eſpecially in plethoric perſons; becauſe, by an unſeaſonable remedy of this kind, a greater influx of humours to the head is cauſed, and from thence there is great danger of an apoplexy. James from Hoffman.

LETHE, *Aides*, in the *Ancient Mythology*, one of the rivers of hell, ſignifying oblivion or forgetfulneſs: its waters, according to poetic fiction, having the peculiar quality of making thoſe who drank them entirely forget every thing that was paſt; or, according to Virgil, *longa potant oblivia vitæ*.

LETHE, LETH, or LATHE, a meaſureor portion of lands making one of the ancient diviſions in England.

King Alfred divided England into COUNTIES, as it ſtands at preſent; thoſe counties he ſubdivided into hundreds or tithings. The hundred was a diviſion, wherein were a hundred officers to ſecure the peace; the *lethe* or *lathe* comprehended three or four of theſe hundreds.

LETHE was alſo the juriſdiction of a viſcount; or a kind of aſſiſe, held once a year in each village, about Michaelmas. Whether this was inſtituted by Alfred, or not, is a queſtion?

LETHUM, in *Ancient Mythology*, was diſtinguiſhed by the Roman poets from *mors*, or DEATH. See Petronius Arb. ver. 263.

Mr. Spence conjectures, that by *Lethum* they meant that general principle, or ſource of mortality, which they ſuppoſed to have its proper reſidence in hell; and by *mors* or *mortes*, the immediate cauſe of each particular

inſtance of mortality on our earth. The poets give him a robe, but mention his arms being exerted out of it, as reaching at his prey. They hint at his catching people in a net, and his hunting them as they did beaſts, within his toils. They repreſent *Lethum* as nearly related to ſleep; and Valerius Flaccus, in particular, acquaints us, that they were brothers. Val. Flac. viii. ver. 74. Spence's Polymetis, p. 261. 263.

LETTER, *litera*, a character either in print or writing, by which any people have agreed to expreſs one of the ſounds, uſed in conveying their thoughts to each other in ſpeech.

Letter is by ſome defined, a ſimple uncompounded ſound of the voice, that cannot be ſubdivided into any more ſimple, and generally marked with a particular character.

But it muſt be owned that, ſtrictly ſpeaking, a *letter* is not the ſound itſelf, but rather the ſign of a ſound: for γραμμα, *ſitera*, is derived from γεγραμμαι, of γραφω, to *write*; and *litera* is formed from *linea*, the participle of *linere*, *to ſmear*, or *mark*; whence *obliterare* ſignifies *to blot out*.

Where a ſign or character does not expreſs a ſound entirely ſimple, but one reſolvable into ſeveral, it is not ſo properly a *letter* as an abbreviation, containing in itſelf as many *letters* as its power does ſimple ſounds. This is evident in the Latin &, *ſi* and the Greek ξ, ψ, ϛ, &c. which are compoſed of *s*, *i*, *k*, *i*, *ss*, *ps*. *cs*, &c.

On the contrary, a ſimple ſound, though expreſſed by ſeveral characters, is yet to be eſteemed one *letter*; for *th*, *ph*, are *ſingle letters*; as much as φ, θ. and ſ.

The *letters f*, *g*, *h*, *i*, *q*, *u*, *y*, *z*, were unknown to the ancient Romans, as is proved by Dauſquius in his Orthography, where he traces the origin of the ſeveral *letters*. See F, G, H, &c.

Grammarians diſtinguiſh *letters* into *vowels* and *conſonants*; into *mutes*, *diphthongs*, *liquids*, and *characteriſtics*.

The Hebrews divide their *letters* into *gutturals*, as *a*, *h*, *ch*, *gn*, aleph, he, chaph, hain, expreſſed by אהחע; *dentals*, as *z*, *i*, *tz*, *r*, *th*, zain, ſamech, ſade, reiſh, ſchin, expreſſed by זסצרש; *labial*, as *b*, *m*, *v*, *p*, beth, mem, vau, phe, expreſſed by the word בומף *linguals*, or thoſe chiefly formed by the tongue, as *d*, *t*, *l*, *n*, *th*, daleth, reth, lamed, nun, thau, expreſſed by דטלנת; and *palatal*, as *g*, *i*, *c*, *k*, ghimel, jod, caph, koph, expreſſed by גיכק.

Printers diſtinguiſh their *letters* into capital, majuſcule, initial, or upper caſe *letters*, which ſerve for the titles of books, proper names, &c. And minuſcule, *ſmall*, or under-caſe *letters*; which are again divided, according to their ſize, into *pearl*, *nonpariel*, *pica*, *great canon*, &c. They have alſo their flouriſhed *letters*, engraven on wood or metal, which take place of the illuminted *letters* of the ancient manuſcripts.

There are *letters* of various ſizes, or bodies; each of which, again, are ſometimes caſt with the Roman, ſometimes an Italic, and ſometimes an Engliſh, or Black *letter* face. There are alſo bodies with Greek, Hebrew, Arabic, the muſic face, &c.

Letters make the firſt parts or elements of grammar; an aſſemblage of theſe compoſe *ſyllables*, of thoſe *words*, and of theſe *ſentences*.

The ALPHABET of every language conſiſts of a certain number of theſe *letters*, which ought to have a different ſound, figure, and ſignification.

As the difference of articulate ſounds was intended to expreſs the different ideas of the mind, ſo one *letter* was originally intended to ſignify only one ſound, and not, as at preſent, to expreſs ſometimes one ſound, and ſometimes another: which practice has brought a great deal of confuſion into the languages, and rendered the learning of the modern tongues infinitely more difficult than it would otherwiſe have been. This conſideration, together with the poverty of all the known alphabets, and their want of ſome *letters* to expreſs certain ſounds by, has occaſioned ſeveral attempts towards an univerſal alphabet, to contain an enumeration of all ſuch ſingle ſounds or *letters* as are uſed in any language. A thing of very conſiderable uſe; a ſpecimen of which is given us by Mr. Lodwick, in the Philoſophical Tranſactions. See *Univerſal* CHARACTER.

According to Crinitus, Moſes invented the Hebrew *letters*, Abraham the Syriac and Chaldee; the Phœnicians thoſe of Attica, brought into Greece by Cadmus, and thence by the Peláſgians into Italy; Nicoſtrata the Latin; Iſis the Egyptian; and Ulphilas, about three hundred and ſeventy years after our Saviour, thoſe of the Goths.

Yet as to the firſt *letters*, what they were, who firſt invented them, and among what people they were firſt in

80087

uſe, there is ſtill room to doubt; however, ſetting aſide conjectures and prejudice, the buſineſs of antiquity ſeems to lie between the Egyptians and Chineſe. Philo attributes the firſt invention of *letters* to Abraham; Joſephus, St. Irenæus, and others, to Enoch; Bibliander, to Adam; Euſebius, Clement Alexandrinus, Corn. Agrippa, &c. to Moſes; Pomponius Mela, Herodian, Rufus Feſtus, Pliny, Lucan, &c. to the Phœnicians; St. Cyprian, to Saturn; Tacitus to the Egyptians; and ſome to the Ethiopians.

The Egyptian mummies and obeliſks prove a great antiquity on the ſide of the hieroglyphics; but if the Chineſe chronology may be credited, their characters are much more ancient than thoſe of the Egyptians. The Chineſe make Fohi, the firſt of their kings, ſuppoſed by many learned and judicious writers to have been no other than the Patriarch Noah, the inventor of their *letters*, and compute him to have lived two thouſand nine hundred and fifty years before Chriſt; during all which time they pretend to have certain and written accounts in their books. If this holds true, their character muſt be older than Moſes by fourteen hundred years, and even prior to Menes, the firſt king of Egypt, by five hundred years; ſo that the Chineſe *letters* appear to be the moſt ancient of that kind; and the book Yekim, ſaid to be written by Fohi, the moſt ancient book.

But as China is ſo remote, and had ſo little communication with theſe parts of the world, we may reaſonably make another inquiry into the original of *letters* in the hither parts of Aſia, Egypt, and Europe. Here indeed, the Egyptians ſeem to have the beſt title. It is more than probable, from the obeliſks, &c. that their hieroglyphics were the firſt manner of writing, and the original characters in theſe parts, as being prior to Moſes; and were made, at leaſt in great meaſure, while the Iſraelites were ſlaves among them, and conſequently not well qualified for inventions ſo very curious and judicious.

To this ſource the learned Biſhop Warburton aſcribes the origin of alphabetical writing among the Egyptians: for as philoſophy advanced and their learned men wrote much, the exact delineation of hieroglyphic figures became too tedious and too voluminous; and they, therefore, by degrees perfected another character which he calls the running hand of HIEROGLYPHICS, reſembling the Chineſe characters, which being at firſt formed only by the outlines of each figures, became at length a kind of marks.

This running character was denominated by the ancients *hieroglyphical*, and led to the compendious uſe of *letters* by an alphabet, which method of writing, as the ancients inform us, was invented by the ſecretary of an Egyptian king, and firſt uſed for ſecrecy in the conveyance of letters of ſtate, whence it was called epiſtolary writing: but afterwards letters became common, and, as he obſerves, hieroglyphics ſecret and myſterious. This political alphabet, he adds, ſoon occaſioned the invention of a ſacred one, uſed by the prieſts and called *hieroglammatical*. But the preciſe time of the invention of Egyptian *letters* cannot be ſo much as gueſſed at, becauſe hieroglyphics continued in uſe long after *letters* had been found out: it is certain that they were very early, becauſe the invention of them was aſcribed to their Gods. Biſhop Warburton farther conjectures, that Moſes brought *letters* with the reſt of his learning from Egypt, and that he both enlarged the alphabet, becauſe the Hebrew alphabet which he employed in the compoſition of the Pentateuch is conſiderably fuller than that which Cadmus brought into Greece; and altered the ſhapes of the *letters*, reducing them into ſomething like thoſe ſimple forms in which we now find them, in order to prevent the abuſe to which they would be liable as hieroglyphic marks and ſymbolic images. He argues, that, conſidering the importance of *letters* among the Hebrews, with regard to the integrity of their religion, if God had been the immediate author of them, Moſes would have recorded the hiſtory of their invention, as the beſt ſanction of their uſe and beſt ſecurity from the danger of hieroglyphic writing, to which this people, ſo fond of Egyptian manners, were very powerfully inclined. Divine Legation, vol. ii. p. 1. 124, &c. See alſo on this ſubject Sharpe's Origin of Languages, p. 56, &c.

Many of the fathers and ſome learned men among the moderns, have imagined that the knowledge of alphabetic writing was either ſupernaturally imparted to our firſt parents, or diſcovered very ſoon after the creation by the effort of their own powers. Others have ſuppoſed that alphabetical *letters* were introduced very early after the deluge, about the time of the diſperſion of mankind, to which period the records of the Chaldean aſtronomy very nearly extend. Mr. Shuckford, who ſuppoſes that they were invented both in Aſſyria and Egypt, conjectures that the great project of Babel, next to the building of the Tower, was the improvement of language, by diſſolving the monoſyllables, of which the firſt language of mankind conſiſted, into words of various lengths, in order to obtain new ſets of names for new things; and that a project of this kind might gradually lead to the invention of alphabetical *letters*. Conn. of Sacred and Prof. Hiſt. vol. i. p. 248.

But to theſe conjectures it may be replied, that we have no authentic relation of any alphabetic character before the flood; the account of the inſcription upon pillars by the firſt Mercury from Manetho, or of Seth mentioned by Joſephus, being too fabulous to deſerve credit. Beſides, if they had been in uſe among the patriarchs after the deluge, many occaſions occur, in which they would not have been omitted: and as we have no account of the uſe of alphabetic characters in epiſtles or contracts, or for other purpoſes to which they would naturally be applied, we may infer that they were not known. To which we may add, that none of the revelations of God to the patriarchs, were enjoined to be recorded till the giving of the law. Others have aſcribed the invention of *letters* to the Arabs, before the time of Moſes; but when we conſider the rudeneſs of their lives and manners, this opinion is by no means probable: and, therefore, the greater number of writers, among Jews and Chriſtians, both ancient and modern, have contented themſelves with tracing their origin to Moſes, ſuppoſed to be the ſame with the Egyptian Thoth or Hermes, mentioned in the hiſtory of that nation; alledging that God taught him the uſe of alphabetic *letters*, in the exemplar of the two tables, wrote, as the text aſſures us, with the finger of God; which words can be underſtood to mean only that they were written by a divine order and direction, as is evident by comparing Exod. xxxiv. 27, 28, and ch. x. 4. It has been ſaid by ſome of the advocates of this opinion, that the elements of language were thus ſupernaturally revealed to Moſes upon the firſt arrival of the Iſraelites before Horeb, but that their characters, with the arrangement of them, might be left to his diſcretion. But it ſeems more probable, that *letters* were at this time well known to the Iſraelites, as God thought fit to deliver the firſt elements of their religion in that kind of writing: more eſpecially as the hiſtory of ſo momentous a circumſtance is not recorded; a circumſtance, the memory of which would have been one of the greateſt barriers againſt idolatry. From the Iſraelites, it is ſuppoſed this art of alphabetical writing paſſed to the Syrians, and from them it was communicated to the Phœnicians and Egyptians: though it ſeems probable that it was of a more ancient date among the latter than the time of the decalogue or the delivery of the law on mount Sinai.

Sir Iſaac Newton, in his Chronology, allows the Midianites, ſprung from Abraham by his concubine Keturah, to have inſtructed Moſes in the knowledge of writing.

Nevertheleſs, whether Cadmus and the Phœnicians learnt *letters* from the Egyptians, or from their nearer neighbours of Judea and Samaria, is a queſtion; ſince ſome of the books of the Old Teſtament, being written in *letters*, is more likely to have given them the hint, than the hieroglyphics of Egypt. But when or wherefoever the Phœnicians learnt this art, it is generally agreed, that Cadmus, the ſon of Agenor, firſt brought *letters* to Greece; whence, in the following ages, they ſpread over the reſt of Europe.

Herodotus in his fifth book intitled Terpſichore, informs us, that thoſe Phœnicians who accompanied Cadmus into Greece, and ſettled there, among many other arts and ſciences, introduced into that country the knowledge of *letters*, which the Greeks in his opinion were ignorant of till that time: their firſt *letters* were ſuch as were in uſe among the Phœnicians; but ſome time after they altered them a little, both with regard to their make and ſound; which alteration ſome have ſuppoſed to have been the change of the Hebrew Characters into thoſe that were afterwards called the Samaritan: and as at that time many of the neighbouring parts were inhabited by ſuch as were originally Ionians, who alſo had received their *letters* from the Phœnicians, they mixed the one with the other; and hence thoſe characters were termed Phœnician, becauſe they were brought out of Phœnicia into Greece. Herodotus alſo adds, that he ſaw at Thebes in Bœotia, in the temple of Iſmenian Apollo, three tripods, that had inſcriptions upon them in Cadmeian *letters*, which very much reſembled the Ionic. The time of this expedition of Cadmus into Greece is fixed by ſir Iſaac Newton to about the 1045th year before Chriſt. The number of *letters* which Cadmus brought into Greece, according to Ariſtotle, as cited by Pliny, was eighteen; but according to Plutarch and Pliny himſelf, ſixteen; to which Palamedes, in the time of the Trojan war, added four, and Simonides four: ſo that the Greek alphabet was gradually perfected. The alterations and improvements

introduced into Greece have led ſome writers to aſcribe the invention of the alphabet to the Greeks: thus Voſſius, de Artc Gram. lib. i. cap. 10. aſſerts that Cecrops, who was much older than Cadmus, was the firſt author of the Greek *letters*; and others aſcribe them to Lancus or to Palamedes. Diod. Sic. lib. iii. Tacitus lib. xi. cap. 14. But the more general opinion of the ancient writers is, that they were derived from the Phœnicians and Egyptians. Diodorus lib. v. ſays expreſsly, that they were invented by the Syrians, and communicated by them to the Phœnicians, who changed the forms of the characters, brought into Europe by Cadmus. Pliny, Nat. Hiſt. lib. vii. cap. 56. ſays, that he is of opinion, that they were Aſſyrian, though he acknowledges that others thought they were invented by the Egyptians, and that Mercury was their firſt author. Diodorus, lib. ii. aſcribes the invention of them to the ſame perſon; and likewiſe Plutarch Sympoſ. lib. xi. cap. 2. and Cicero de Natura Deorum, lib. iii. And the æra of this invention is computed by chronologers to be as early as the year of the world 2054, and before the incarnation 1950 years. The Greeks retained the names and orders of ſeveral of the oriental or Cadmean *letters*, though they altered the form of them; and there are ſeven *letters*, viz. Γ, Δ, H, K, Λ, P, T, whoſe original figures were retained by the Greeks with little variation. As to the Latins, all writers agree, that they received their *letters* from the Greeks, being firſt taught the uſe of them by ſome of the followers of Pelaſgus, who came into Italy about one hundred and fifty years after Cadmus came into Greece; or by the Arcadians, whom Evander led into thoſe parts about ſixty years after Pelaſgus. Pliny, lib. vii. cap. 56. and Solinus imagined the Pelaſgi to have been the firſt authors of the Latin *letters*; but Tacitus lib. xi. p. 131. was of opinion, that the firſt Italians were taught *letters* by the Arcadians; and Dionyſius Halicarnaſſus, lib. ii. expreſsly affirms the ſame thing. That the Latin *letters* were derived from the Greek ſeems very probable from the ſimilitude which the ancient *letters* of each nation bore to one another. Tacitus, Annal. lib. xi. obſerves, that the ſhape of the Latin *letters* reſembled that of the moſt ancient Greek ones; and the ſame obſervation was made by Pliny, lib. vii. cap. 58. and confirmed from an ancient table of braſs inſcribed to Minerva. Scaliger Digreſſ. ad Annum Euſeb. 1617, and Voſſius lib. i. cap. 24, 25. have adopted and ſupported the ſame opinions. See thoſe citations in Shuckford's Conn. vol. i. p. 223, &c.

Thus we find, that Greece was the centre from which the rays of ſcience ſhot into the weſtern world; and the barbarous nations who penetrated into Italy towards the cloſe of the Roman empire, carried arts and learning back into the North; or the knowledge of *letters* might be introduced among the northren nations from the borders of Aſia in an earlier age. Sharpe's Original Powers of *Letters*. Obſervations on Alphabetical Writing, 1772. See WRITING.

Rudbeck, who, in his Atlantica, claims the glory of all inventions, from all other nations, for the Swedes, maintains, that the Ionians had letters before Cadmus; that at the time of the ſiege of Troy, the Greeks had but ſixteen *letters*, whereas the Phœnicians had twenty-two; whence he concludes, that it was not either Cadmus, or the Phœnicians, who taught this art to the Greeks. But, becauſe the ancient northern nations had juſt ſixteen *letters*, like the Greeks, he concludes, the Greeks muſt either have taught them to the people of the North, or have learnt them of them. But becauſe the form and make of the Runic *letters* is more artleſs and coarſe than that of the Greek *letters*, he concludes, that theſe laſt muſt be derived from the former; taking it as a principle, that thoſe who derive any thing from another, poliſh and improve it. He even aſſerts, that by the golden apples which Hercules was obliged to ſteal, muſt be underſtood the *letters* in uſe among the Hyperboreans.

There are few things on which there has been ſo much written as on the original Hebrews *letters*. Origen, Euſebius Cæſarienſis, St. Jerom, &c. have made it the ſubject of their enquiry. See HEBREW and SAMARITAN.

The art of joining *letters* to form words, and of combining the one and the other an infinite number of different ways, is a ſecret unknown to the Chineſe. Inſtead of the alphabetical *letters*, they at firſt, like the Egyptians, uſed hieroglyphics; they painted, rather than wrote; ſtriving, by the natural image of things drawn on paper, to expreſs and communicate their ideas to one another.

To remedy the inconveniences of this method, they changed, by little and little, their manner of writing, making it more ſimple, though leſs natural. They even invented ſeveral characters, to expreſs things that did not come within the reach of painting to repreſent: as voice, ſmell, thoughts, paſſions, and a thouſand other objects that have no body or figure. From ſeveral ſimple ſtrokes they afterwards framed others more compound; and in this manner multiplied the *letters* and characters to infinity, contriving one, or more, for every word.

This multitude of *letters* ſeems the ſource of that ignorance which we find among the Chineſe; their whole lives being ſpent in learning their *letters*, they have no time to apply themſelves to the ſtudy of things, but think themſelves very learned when they are able to read. There are ſcarce any of them that know all their *letters*; they think it is a great progreſs they have made, when, after forty or fifty years hard ſtudy, they are able to underſtand fifteen or twenty thouſand. But the generality of their learned men come ſhort of this. Father Le Compte is of opinion, that the greateſt doctor among them never underſtood half of their *letters* well; for the whole number he reckons eighty thouſand. This is a prodigious inconvenience to foreigners, of which the miſſionaries in that country make loud complaints.

Among the Chineſe *letters*, there are ſome now almoſt wore out of uſe, and only preſerved out of reſpect to antiquity. There is a ſecond claſs, much leſs ancient than the former, only uſed in public inſcriptions. A third, much more regular and beautiful, uſed in printing, and even in ordinary writing. However, as the ſtrokes are to be diſtinctly formed, they cannot be wrote with any expedition. For this reaſon, they have invented a fourth kind, where the ſtrokes, being cloſer, and leſs diſtant from each other, allow them to be writ with more eaſe and readineſs; and this they call the *running letter*. See CHINESE *tongue*.

The Americans had no *letters* before the diſcovery of that country by the Spaniards. The Acauithus engrave their memorable events and epochas on ſtones and metals; their ſongs ſupply the reſt. In Peru and Chili, to keep an account of their goods and chattels, and to preſerve the memory of their particular affairs, the Indians have recourſe to certain knots of wool; which, by the variety of their colours and ties, ſerve inſtead of characters, and writing. The knowledge of theſe knots, which they call *quipos*, is one of their great ſciences; but which is always kept as a ſecret, and never revealed to the children, till the fathers think themſelves at the end of their days.

LETTER, *dominical*. See DOMINICAL.

LETTER *double*. See DOUBLE.

LETTER, *final*. See FINAL.

LETTER, *guttural*. See GUTTURAL.

LETTER, *foundery*. See FOUNDERY.

LETTER *founders furnace*. See FURNACE.

LETTER *founders mould*. See MOULD.

LETTER *labial*. See LABIAL.

LETTERS, *numeral*, are thoſe uſed inſtead of ciphers, to expreſs numbers.

The Roman numerals are, C, D, I, L, M, V, X; which are all formed by deſcribing a circle, and drawing two lines through it, croſſing each other at right angles in the centre. See CHARACTER.

LETTER, *mundinal*. See MUNDINAL.

LETTER is alſo a writing addreſſed and ſent to one. See EPISTLE.

By 9 Geo. I. cap. 22. amended by 27 Geo. II. cap. 15. knowingly to ſend any *letter* without name, or with a fictitious name, demanding money, &c. or threatening, without any demand, to kill, or fire the houſe of any perſon, is made felony, without benefit of clergy. And by 30 Geo. II. cap. 24. perſons ſending *letters* with or without a name, or with a fictitious name, threatening to accuſe any one of a crime puniſhable by law with death, tranſportation, pillory, or any other infamous puniſhment, in order to extort money or goods, ſhall be puniſhed at the diſcretion of the court, by fine and impriſonment, pillory, whipping, or tranſportation for ſeven years.

LETTERS *of abſolution* were formerly granted by an abbot to releaſe any of his brethren from the obligation of ſubjection and obedience, and to make them capable of entering into any other religious order.

LETTER *of attorney*, in *Law*, a writing authorizing an attorney to do ſome legal act in our ſtead: as, to give ſeiſin of lands, to receive debts, to ſue a third perſon, &c. And *letters of attorney* are either general or ſpecial. Weſt. Symb. par. i. ſtat. 7 R. II. cap. 13.

The nature of this inſtrument is to give the attorney the full power and authority of the maker, to accompliſh the act intended to be performed. Sometimes theſe writings are revocable, and ſometimes not ſo; but when they are revocable, it is uſually a bare authority only; and they are irrevocable, when debts, &c. are aſſigned to another; in which caſe the word irrevocable is inſerted.

LETTERS *close*, or *cloſe*, in *Law*, are oppoſed to LETTERS *patent*. See CLOSE-*rolls*.

LETTER *of credit*, among *Merchants*. See CREDIT.

LETTERS *communicatory*. See LITERÆ *communicatoriæ*.

LETTER *of exchange*. See BILL and EXCHANGE.

LETTER *of licence*, in *Trade*, an inſtrument, or writing, granted to a man who has failed, or broke, ſigned and ſealed by his creditors; which *letter* uſually gives a longer time for payment: ſo that the debtor, having ſuch an aſſurance, may go about his buſineſs without fearing an arreſt.

LETTERS *of mart*, or *marque*, are *letters* under the privy ſeal, granted to the king's ſubjects; impowering them to take, by force of arms, what was formerly taken from them by the ſubjects of ſome other ſtate, contrary to the law of mart. See MARQUE.

LETTERS *of marque*, in the Britiſh dominions, are to be granted by the admiralty; and they empower the commander of a merchant ſhip or privateer, to cruiſe againſt and make prizes of the enemy's ſhips and veſſels, either at ſea, or in their harbours.

LETTER, *miſſive*, in the *Ritoliion of a Biſhop*. See BISHOP.

LETTER, *miſſive*, in *Chancery*. If a peer is defendant in this court, the lord chancellor ſends a *letter miſſive* to him, to requeſt his appearance, together with a copy of the bill: if he neglects to appear, then he may be ſerved with a ſubpœna; if he continues ſtill in contempt, a ſequeſtration iſſues out immediately againſt his lands and goods, without any of the meſne proceſs of attachments, &c. which are directed only againſt the perſon, and therefore cannot affect a lord of parliament. The ſame proceſs iſſues againſt a member of the houſe of commons, except that the lord chancellor does not ſend him any *letter miſſive*.

LETTERS *patent*, or *overt*, are writings ſealed with the great ſeal of England, whereby a man is authorized to do or enjoy any thing, which of himſelf he could not do. They are ſo called, on account of their form; as being open, with the ſeal affixed, ready to be ſhewn for the confirmation of the authority given by them.

Common perſons may grant *letters patent*; but they are rather called *patents*, than *letters patent*; yet, for diſtinction, thoſe granted by the king are ſometimes called *letters patent royal*.

Letters patent conclude with *teſte meipſo*; charters, with *his teſtibus*. See PATENT.

LETTERS *of reſpite*, *letters* iſſued out by a prince, in favour of honeſt, untortunate debtors, againſt too rigorous creditors, whereby payment is delayed for a certain term.

The uſe of theſe *letters* is very ancient. Caſſiodorus obſerves, they were in uſe in the time of Theodoric, king of the Goths; others will have them introduced towards the end of the eleventh century, by pope Urban II. in favour of thoſe who went on the croiſades.

They are ſtill in uſe in France, and ſome other countries, and take their name, *à reſpirando*, becauſe they give the debtor a breathing time.

St. Louis granted three years reſpite to all who made the voyage of the Holy Land with him.

LETTERS *circular*, *dimiſſory*, *frank*, *monitory*, *pacific*, *paſchal*. See the ſeveral adjectives.

LETTERS *of ſafe-conduct*. See SAFE-*conduct*.

LETTERED, *letterates*. See LITERATI.

LETTUCE, *lactuca*, in *Botany*, a genus of the *ſyngeneſia polygamia æqualis* claſs. Its characters are theſe: the flowers are compoſed of ſeveral hermaphrodite florets, incloſed in a ſcaly oblong impalement; the florets have one petal, which is ſtretched out on one ſide like a tongue, and ſlightly indented at the end in three or four parts; theſe have five ſhort hairy ſtamina; the germen afterwards becomes one oblong pointed ſeed, crowned with a ſingle down.

We have the ſeveral ſpecies of *lettuce* cultivated in the kitchen-gardens about London, all of which are excellent ſallad herbs, and ſucceed one another in their ſeveral ſeaſons. The ſeveral kinds are, 1. The common *lettuce*. 2. The cabbage-kind. 3. The Sileſia or Cilicia. 4. The Dutch-brown. 5. The Aleppo. 6. The imperial. 7. The green capuchin-*lettuce*. 8. The Verſailles, or upright white cos-*lettuce*. 9. The black cos. 10. The white cos-*lettuce*. 11. The red capuchin-*lettuce*. 12. The Roman-*lettuce*. 13 Prince-*lettuce*. 14. The royal *lettuce*, and 15. The Egyptian cos-*lettuce*.

The firſt of theſe ſorts is very common in all gardens, and is commonly ſown for cutting very young, to mix with other ſallad herbs in ſpring; and the ſecond, or cabbage-*lettuce* is only this, tended by culture. It may be ſown at all times of the year, but in the hot months requires to be ſown in ſhady borders. The cabbage-*lettuce* may alſo be ſown at different ſeaſons to have a continuation of it through the ſummer. The firſt crop ſhould be ſown in February in an open ſituation; the others, at three weeks diſtance, but the latter ones under covert, but not under the drippings of trees.

The Sileſia, imperial, royal, black, white, and upright cos-*lettuces*, may be ſown firſt in the latter end of February or the beginning of March, on a warm light ſoil, and in an open ſituation; when the plants are come up, they muſt be either hoed out, or tranſplanted into another ſpot of ground, leaving them fifteen inches diſtance apart every way. They will then require no farther care than the keeping them clear of weeds; and the black cos, as it grows large, ſhould have its leaves tied together to whiten the inner part. Succeeding crops of theſe ſhould be ſown in April, May, and June, and toward the middle of September they may be ſowed for a winter crop, to be preſerved under glaſſes, or in a bed arched over with hoops, and covered with mats: and in ſpring they ſhould be planted out in a rich light ſoil, allowing them at leaſt eighteen inches diſtance every way.

The moſt valuable of all the Engliſh *lettuces*, are the Egyptian green cos, the white cos, or the Verſailles, the Sileſia, and the black cos. The brown Dutch and the green capuchin are very hardy, and may be ſown late, under walls, where they will ſtand the winter, and be valuable, when no others are to be had. The red capuchin Roman, and prince-*lettuce*, are very early kinds, and are ſown for variety, as are alſo the Aleppo ones for the beauty of their ſpotted leaves.

The young leaves of the ſeveral varieties of garden-*lettuce* are emollient, cooling, in ſome ſmall degree laxative and aperient, eaſy of digeſtion, but of little nouriſhment; ſalubrious in hot bilious indiſpoſitions, but leſs proper in cold phlegmatic temperaments. In ſome caſes they tend to promote ſleep by virtue of their refrigerating and demulcent quality. Lewis.

The milk of the common garden *lettuces* is hypnotic, while the root of the plant is cooling, effluent, and nouriſhing. Dr. Alſton. ap. Med. Eſſ. Edinb. vol. v. art. 12.

LETTUCE, *hare's*. See *Sow's Thiſtle*.

LETTUCE, *lamb*. See VALERIAN.

LETTUCE, *wild*, *prenanthes*, in *Botany*. Its characters are theſe: it hath a ſmooth cylindrical empalement, having many ſcales, which are equal, but have three at the baſe unequal: this common empalement includes from five to eight hermaphrodite florets, diſpoſed in a ſingle round order: they have one petal, which is ſtretched out like a tongue, and indented in four parts at the end; they have five ſhort hair like ſtamina, terminated by cylindrical ſummits; the germen is ſituated under the petal, ſupporting a ſlender ſtyle longer than the ſtamina, crowned by a bifid reflexed ſtigma; the germen afterwards becomes a ſingle heart-ſhaped ſeed, crowned with hairy down. Miller enumerates four, and Linnæus nine ſpecies.

Theſe plants are ſeldom admitted into gardens, but if any perſon is deſirous to cultivate them, and will ſow the ſeeds ſoon after they are ripe in a ſhady ſituation, the plants will require no other care than to keep them clear from weeds. Miller.

LEVANDIS *militum expenſis*. See EXPENSIS.

LEVANT, in *Geography*, ſignifies any country ſituate to the eaſt of us, or the eaſtern ſide of any continent or country, or that on which the ſun riſes.

LEVANT, in *Matters of Commerce*, &c. is generally reſtrained to the Mediterranean ſea; or, rather, to the country on the eaſtern part of it.

Hence, our trade thither is called the *Levant trade*; and a wind that blows from thence, out of the Streights mouth, is called a *Levant wind*.

France was the firſt nation that made treaties of commerce with the Porte. The ſieur de la Foret ſigned them in 1535, in the name of Francis I. and thereby obtained many privileges in favour of that kingdom; which they alone enjoyed, until the Venetians, the Engliſh, the Hollanders, and at length the Genoeſe, likewiſe, obtained particular privileges for themſelves.

LEVANT, *meaſures*. See MEASURE.

LEVANT, *bole of the*. See BOLE.

LEVANT *and couchant*, in *Law*, is, when cattle have been ſo long in another man's ground, that they have laid down, and riſen again to feed, which in general is held to be one night, at leaſt.

LEVARE *antiphonum*, in the *Muſic of the Romiſh Church*, is to begin or open the firſt note of an anthem.

LEVARI *facias*, in *Law*, a writ directed to the ſheriff for levying a ſum of money on a man's lands and tenements, who has forfeited his recognizance; in virtue of which the ſheriff may ſeize all his goods, and receive the rents and profits of his lands, till ſatisfaction be made to the plaintiff: but this writ has now given way to the remedy by ELEGIT. There is alſo a *levari facias damna diſſeiſitoribus*, for the levying of damages, wherein the diſſeiſor has been formerly condemned to the diſſeiſee; and alſo a *levari facias reſiduum debiti*, to levy the remainder of a debt upon lands and tenements, or chattels of the debtor, where part has been ſatisfied before. And further, a *levari facias quando vicecomes returnavit quod non habuit emptores*, commanding the ſheriff to ſell the goods of the debtor

debtor which he has taken, and returned that he could not ſell.

LEVATIO *arietum*. See ARIETUM.

LEVATOR, in *Anatomy*, an epithet which anatomiſts give to ſeveral muſcles, whoſe uſe is to riſe, or lift up, the parts to which they belong. See ELEVATOR.

There are *levators* of the eye-lids, of the omoplate, of the anus, of the ſcapula, &c.—See *Tab. Anat. (Myol.) fig.* 2. *n.* 3.

LEVATORES *ani*, in *Anatomy*. Theſe muſcles ariſe fleſhy from each ſide of the oſſa pubis, internally within the pelvis; as alſo from part of the os ſchium and ſacrum. From theſe places like lines drawn from a circumference toward a centre, their fibres deſcend over the muſculi maſſupiales, to their implantation at the lower end of the inteſtinum rectum in the anus. The uſe of theſe muſcles is principally to ſuſpend and draw the anus upward, leſt the fæces ſhould be burthenſome to the ſphincter. In their deſcent on each ſide forward, from the oſſa pubis, they paſs cloſely over the glandulæ proſtatæ, in a manner embracing them: by which mechaniſm they are rendered capable of compreſſing them; and by a retraction of the anus, at the ſame time act on the veſiculæ ſeminales, in order to promote the emiſſion of the ſeminal juices in coition.

LEVATOR *coccygis*, in *Anatomy*, a name given by many to the muſcle, now generally known by the name of COCCYGÆUS.

LEVATORES *breviores coſtarum*, in *Anatomy*, the modern name introduced by Albinus for certain muſcles of the ribs, called by others the *ſupracoſtales*, the *ſur coſtaux* of the French, and the *ſcaleni quarti* by ſome. Steno was the firſt who called them *levatores coſtarum*, from their office: he is followed in this by Morgagni and Albinus, who, adding the word *breviores*, by way of diſtinction from ſome other longer ones, called *ſupracoſtales longi* by authors, have formed the modern name.

LEVATOR *internus*, in *Anatomy*, a name given by Douglas, and ſome others, to a muſcle, now generally called only the *levator ani*.

LEVATOR *labii ſuperioris*, in *Anatomy*, a name given by Albinus to a muſcle, called by Santorini and Winſlow the *inciſorius*, and by Cowper the ELEVATOR *labii ſuperioris*, and by Spigelius *alas noſi abducens*.

LEVATOR *menti*, in *Anatomy*, a name given by Albinus to a muſcle of the face, called by Cowper and others ELEVATOR *labii inferioris*, and by ſome the INCISIVUS *inferior*.

LEVATOR *palpebræ ſuperioris*, in *Anatomy*, a name given by Albinus to a muſcle of the face, called by Cowper, Douglas, and the generality of writers, *aperiens palpebram* and APERIENS *palpebram rectus*.

LEVATOR *proſtatæ*, in *Anatomy*, a name given by Santorini, and ſome others, to a muſcle, called by Winſlow, *proſtaticus ſuperior*, and by Albinus *compreſſor proſtatæ*.

LEVATOR *ſcapulæ propriur*, in *Anatomy*, a long and pretty thick muſcle, about two fingers in breadth, lying above the ſuperior angle of the ſcapula, along the poſterior lateral part of the neck of that bone. It is inſerted above, in the extremities of the tranſverſe apophyſes of the four firſt vertebræ of the neck by four fleſhy branches, ending in ſhort tendons. Sometimes the ſecond, ſometimes the third, or both; and ſometimes the third of theſe branches is wanting, theſe defects being made up by the largeneſs of the reſt: from thence theſe branches run down a little obliquely, and then uniting together, they are inſerted in the ſuperior angle of the ſcapula, and in the edge of its baſis from thence to the ſmall triangular ſpace, being there covered a little by the rhomboides. This muſcle is eaſily divided into two through its whole length. It is covered by the trapezius, and its inſertions in the neck are ſometimes mixed with thoſe of the neighbouring muſcles. Winſlow.

LEVATUM. See TERRIS *& Catalis tentis ultra debitum*.

LEUCACANTHA, in *Botany*, a name uſed by Dioſcorides and the other Greek writers, for the acacia tree, which produces the gum arabic, but it was alſo uſed for a kind of prickly plant, called alſo AMGAILA by ſome of the Arabians; as being a plant whoſe roots were knotted and jointed. Theſe joints were ſeparated and dried, and then uſed in medicine as cardiacs and carminatives, under the names of BUNE or *bunion*. They were of a very agreeable aromatic ſmell, and very little taſte; and the ancients always preferred ſuch of them as were yellow and light, rejecting thoſe which were heavy and white, and which wanted ſmell. It is not well known at this time what theſe roots were; but it is neceſſary, in order to the right underſtanding the works of the ancients, to know that there were ſuch roots; and that though called by the ſame name with the gum arabic tree, they were of a very different nature.

LEUCACHATES, in *the Natural Hiſtory of the Ancients*, the name of an agate, not a peculiar ſpecies, but only a particular appearance of the lead-coloured agate called PHASISACHATES.

LEUCADENDRON, in *Botany*, a genus of the *tetrandria monogynia* claſs: the corolla of which is floſculous, conſiſting of two petals, joined to another which is trifid: the receptacle is hairy; this genus has no proper calyx, and the antheræ are connected at their baſe. Linnæus enumerates ſixteen ſpecies.

LEUCANTHEMUM, in *Botany*. See DAISY and *Corn* MARYGOLD.

LEUCELECTRUM, a name given by ſome authors to that ſort of AMBER, which is white and opake, and uſually of a fatty look.

LEUCIŚCUS, in *Ichthyology*. See DACE.

LEUCOCROTTA, in *Natural Hiſtory*, the name given by many authors to a beaſt, ſuppoſed to be the ſwifteſt of all creatures in the world: others have called it *leucocrotta*, but the true name is LEUCROCOTTA.

LEUCODENDROS, in *Botany*, a name given to the SILVER PINE-*tree*.

LEUCOGÆA, in *Natural Hiſtory*, a name by which ſome authors have called the ſubſtance, more uſually known by the name of MOROCHTHUS, and called in Engliſh, French chalk, or Briançon chalk.

LEUCOGRAPHIS, in *Natural Hiſtory*, the name uſed by ſome of the ancient writers, for the ſubſtance commonly called MOROCHTHUS, or *French chalk*.

LEUCOIUM, in *Botany*. See *Great* SNOW *Drop*.

LEUCOIUM *ſudeum & luteum*. See STOCK *Gilly Flower*.

LEUCOIUM *bulboſum*. See SNOW-*Drop*.

LEUCOLIBANON, in the *Materia Medica of the Ancients*, a name given to the white olibanum, or FRANKINCENSE, which they carefully diſtinguiſh from the reddiſh or yellowiſh olibanum. This was alſo called *argelibanum*, or the ſilver-coloured olibanum; and the yellow one *chalcelibanum*. This latter word is uſed in the Apocalypſe of St. John, and is miſunderſtood ſo far as to be tranſlated braſs, and ſuppoſed to be a kind of braſs from mount Lebanon. See CHALCOLIBANON.

LEUCOLITHOS, in *Natural Hiſtory*, a name given by ſome of the Greek writers to the *pyrites argenteus*, or ſilvery PYRITES. The ancients had a great opinion of theſe foſſils in diſeaſes of the eyes; they uſed all the kinds of pyrites, or marcaſite, after calcination, for this purpoſe; but as they diſtinguiſhed four kinds of them, they attributed theſe virtues, in different degrees, to the different kinds; therefore they had recourſe to ſo many peculiar names for diſtinguiſhing them; and the white kind was called *leucolithos*, to diſtinguiſh it from the duſky one called the *iron pyrites*, and the deeper and paler yellow kinds, called the *gold* and *braſſy marcaſites*.

LEUCOMA, Λευκωμα, among the Athenians, ſignified a public regiſter of the whole city, in which were written the names of all the citizens, as ſoon as they came to be of age to enter upon their paternal inheritance.

LEUCOMA, Λευκωμα, from λευκος, *white*, in *Surgery*, a little white ſpot on the cornea of the eye; called by the Latins ALBUGO.

LEUCOMÆNAS, in *Ichthyology*, a name by which ſome have called the SMARIS, a ſmall fiſh caught in great plenty in the Mediterranean.

LEUCÓ *narciſſi lirion*. See SNOW-*Drop*.

LEUCOPETALOS, in *Natural Hiſtory*, the name of a beautiful ſtone deſcribed by Pliny, as being of a fine gold yellow, variegated with white.

LEUCOPETRIANS, in *Eccleſiaſtical Hiſtory*, the name of a fanatical ſect which ſprung up in the Greek and Eaſtern churches towards the cloſe of the twelfth century: the fanatics of this denomination profeſſed to believe in a double Trinity, rejected wedlock, abſtained from fleſh, treated with the utmoſt contempt the ſacraments of baptiſm and the Lord's ſupper, and all the various branches of external worſhip, placed the eſſence of religion in internal prayer alone, and maintained, as it is ſaid, that an evil being, or genius, dwelt in the breaſt of every mortal, and could be expelled from thence by no other method than by perpetual ſupplication to the ſupreme Being. The founder of this enthuſiaſtical ſect, is ſaid to have been a perſon called Leucopetrus, and his chief diſciple Tychicus, who corrupted, by fanatical interpretations, ſeveral books of ſcripture, and particularly St. Matthew's goſpel. Moſheim

LEUCOPHAGIUM, a name given by ſome phyſicians to a ſort of medical aliment good in conſumptions, and other general decays. It is compoſed of ſweet almonds macerated in roſe-water, with the tender fleſh of a capon, all being finally boiled together to a pulp, capable of being paſſed through a ſieve.

LEUCOPHLEGMATIA, Λευκοφλεγματια, formed from λευκος, *white*, and φλεγμα, *pituita, phlegm*, a kind of dropſy, otherwiſe called ANASARCA.

The *leucophlegmatia* conſiſts in a tumor, or bloating, of the whole outer ſurface of the body, or ſome of its parts; white and ſoft, eaſily giving way to the touch, and pre-

ſerving the impreſſion made by the finger for ſome time. It may either be owing to ſome diſorder of the blood; which, in this diſeaſe, is of a pale colour, viſcid, and cold; or to an aqueous humour extravaſated, and gathered together in the muſcles, and the pores of the ſkin. See DROPSY.

LEUCOPIPER, in the *Materia Medica*, a name by which ſome authors have diſtinguiſhed the white pepper.

LEUCORHŒA, a name given by ſome medical writers to the whites, or FLUOR *albus*, a very troubleſome diſeaſe to women.

LEUCORODIUS, in *Ornithology*, a name by which ſome have called the platea, or SPOONBILL, a very remarkable kind of ſtork or heron.

LEUCOSTAPHYLOS, in *Botany*, a name given by ſome authors to the water-elder, or opulus.

LEVEL, an inſtrument wherewith to draw a line parallel to the horizon, and continue it out at pleaſure; and, by this means, to find the true *level*, or the difference of aſcent or deſcent, between ſeveral places, for conveying water, draining fens, &c.

The word comes from the Latin *libella*, the croſs beam that forms the brachia of a balance; which, to be juſt, muſt ſtand horizontally.

There are ſeveral inſtruments, of different contrivance and matter, invented for the perfection of *levelling*; all of which, for the practice, may be reduced to theſe that follow.

LEVEL, *air*, that which ſhews the line of *level*, by means of a bubble of air, incloſed with ſome liquor in a glaſs tube of an indeterminate length and thickneſs, whoſe two ends are ſealed hermetically, that is, are cloſed with the glaſs itſelf, by heating it with the flame of a lamp, till it becomes ſoft and tractable. When the bubble of air fixes itſelf at a certain mark, made exactly in the middle of the tube, the plane, or ruler, wherein it is fixed, is *level*. When it is not *level*, the bubble will riſe to one end.

This glaſs tube may be ſet in another of braſs, having an aperture in the middle, whence the bubble of air may be obſerved.

The liquor wherewith the tube is filled, is ordinarily either oil of tartar, or aqua fecunda; thoſe not being liable to freeze as common water; nor to rarefaction and condenſation, as ſpirit of wine is.

The invention of this inſtrument is aſcribed to M. Thevenot.

LEVEL, *air, with ſights*, is an improvement of that laſt deſcribed; which, by the addition of more apparatus, becomes more commodious and exact.

It conſiſts of an *air-level* (*Tab. Surveying, fig.* 13) about eight inches long, and ſeven or eight inches in diameter, ſet in a braſs tube, with an aperture in the middle. The tubes are carried in a ſtrong, ſtrait ruler, a foot long, at whoſe ends are fixed two ſights, exactly perpendicular to the tubes, and of an equal height, having a ſquare hole, formed by two fillets of braſs, croſſing each other at right angles; in the middle whereof is drilled a very little hole, through which a point on a *level* with the inſtrument is deſcried. The braſs tube is faſtened on the ruler by means of two ſcrews; one whereof, marked 4, ſerves to raiſe or depreſs the tube at pleaſure, for bringing it towards a *level*. The top of the ball and ſocket is riveted to a little ruler that ſprings; one end whereof is faſtened with ſcrews to the great ruler, and the other end has a ſcrew 5, ſerving to raiſe and depreſs the inſtrument, when nearly *level*.

This inſtrument is yet leſs commodious than the following one; becauſe, though the holes be ever ſo ſmall, yet they will ſtill take in too great a place to determine the point of *level* preciſely.

LEVEL, *air, with teleſcope ſights*. This *level*, repreſented in *Tab. Surveying, fig.* 14. is like the laſt; with this difference, that, inſtead of plain ſights, it carries a teleſcope to determine exactly a point of *level* at a good diſtance.

The teleſcope is in a little braſs tube, about fifteen inches long, faſtened on the ſame rule as the *level*. At the end of the tube of the teleſcope marked 1, enters the little tube 1, carrying the eye-glaſs, and a hair horizontally placed in the focus of the object-glaſs 2; which little tube may be drawn out, or puſhed into the great one, for adjuſting the teleſcope to different ſights. At the other end of the teleſcope is placed the object-glaſs; the ſcrew 3 is for raiſing or lowering the little fork carrying the hair, and making it agree with the bubble of air when the inſtrument is *level*; and the ſcrew 4 is for making the bubble of air agree with the teleſcope. The whole is fitted to a ball and ſocket.

M. Huygens is ſaid to have been the inventor of this *level*; which has this advantage, that it may be inverted, by turning the ruler and teleſcope half round; and if then, the hair cut the ſame point that it did before the turn, it is a proof the operation is juſt.

It may be obſerved, that one may add a teleſcope to any kind of *level*, by applying it upon, or parallel to, the baſe, or ruler, when there is occaſion to take the *level* of remote objects.

For the method of adapting a *level* to the meridian teleſcope. See TELESCOPE.

Mr. Hadley has contrived a ſpirit *level* to be fixed to a quadrant for taking a meridional altitude at ſea, when the horizon is not viſible. See the deſcription and figure of it in the Phil. Tranſ. N° 330, p. 167, &c. or Martyn's Abridg. vol. viii. p. 358, &c. See alſo the method of preparing and uſing a water *level*, and a mercurial *level*, annexed to Davis's quadrant, for the ſame purpoſe, by Mr. Leigh, in Phil. Tranſ. N° 451. p. 413. or Abr. vol. viii. p. 360, &c.

LEVEL, *foot*. See FOOT-*level*.

LEVEL, *artillery-foot*, is in form of a ſquare, having its two legs or branches, of an equal length; at a juncture whereof is a little hole, whence hangs a thread and plumbet, playing on a perpendicular line in the middle of a quadrant: it is frequently divided into 90 degrees, or rather into twice 45 degrees from the middle. See *fig.* 18. *lit.* F.

This inſtrument may be uſed on other occaſions, by placing the end of its two branches on a plane; for when the thread plays perpendicularly over the middle diviſion of the quadrant, that plane is allowedly *level*.

To uſe it in gunnery, place the two ends on the piece of artillery, which you may raiſe to any propoſed height by means of the plumbet, whoſe thread will give the degree above the *level*.

LEVEL, *carpenters and paviors*, conſiſts of a long ruler, in the middle whereof is fitted, at right angles, another ſomewhat bigger, at the top of which is faſtened a line with a plumbet; which, when it hangs over a fiducial line at right angles with the baſe, ſhews that the ſaid baſe is horizontal.

This and the maſon's *level*, though very common, are eſteemed the beſt for the practice of building, though the operations by them can only be *ſhort*.

LEVEL, *gunners*, for levelling cannons and mortars, is an inſtrument repreſented *Tab. Surveying, fig.* 16. conſiſting of a triangular braſs plate, about four inches high: at the bottom of which is a portion of a circle, divided into 45°, which number is ſufficient for the higheſt elevation of cannons and mortars, and for giving ſhot the greateſt range. On the centre of this ſegment of a circle is ſcrewed a piece of braſs, by means whereof it may be fixed, or moved, at pleaſure. The end of this piece of braſs is made ſo as to ſerve for a plumbet and index, in order to ſhew the different degrees of elevation of pieces of artillery. This inſtrument has alſo a braſs foot to ſet upon cannon or mortars, ſo as when thoſe pieces are horizontal, the whole inſtrument will be perpendicular.

The uſe of this *level* is obvious; and conſiſts in placing the foot thereof on the piece to be elevated; in ſuch manner as that the point of the plumbet may fall on the proper degree: this is what they call *levelling* the piece.

LEVEL, *maſon*, is compoſed of three rules, ſo joined as to form an iſoſceles triangle, ſomewhat like a Roman A; at the vertex whereof is faſtened a thread, from which hangs a plumbet, which paſſes over a fiducial line marked in the middle of the baſe, when the thing to which the *level* is applied is horizontal; but declines from the mark when the thing is lower on one ſide than the other.

LEVEL, *plumb*, or *pendulum*, that which ſhews the horizontal line, by means of another line perpendicular to that deſcribed by its plumbet, or pendulum.

This inſtrument, repreſented *Tab. Surveying, fig.* 18. conſiſts of two legs, or branches, joined together at right angles; whereof that which carries the thread or plumbet is about a foot and an half long. This thread is hung towards the top of the branch, at the point 2. The middle of the branch where the thread paſſes is hollow, that ſo it may hang free every where but towards the bottom, where there is a little blade of ſilver, whereon is drawn a line perpendicular to the teleſcope. The ſaid cavity is covered by two pieces of braſs, making, as it were, a kind of caſe, leſt the wind ſhould agitate the thread; for which reaſon the ſilver blade is covered with a glaſs G, to the end that it may be ſeen when the thread and plumbet play upon the perpendicular. The teleſcope 1 is faſtened to the other branch, or leg, of the inſtrument, and is about two feet long, having a hair placed horizontally acroſs the focus of the object-glaſs, which determines the point of *level*, when the ſtring and plumbet hang againſt the line on the ſilver blade.

All the accuracy of this inſtrument depends on the teleſcope's being fitted at right angles to the perpendicular. It has a ball and ſocket, by which it is faſtened to its foot; and is ſaid to have been the invention of M. Picard.

LEVEL, *reflecting*, is that made by means of a pretty long ſurface of water, repreſenting the ſame object inverted, which we ſee erect by the eye; ſo that the point where thoſe two objects appear to meet, is in a *level* with the place where the ſurface of water is found. This is the invention of M. Mariotte.

There is alſo another *reflecting level*, conſiſting of a mirror of ſteel, or the like, well poliſhed, and placed a little before the object-glaſs of a teleſcope ſuſpended perpendicularly. This mirror muſt make an angle of 45 degrees with the teleſcope; in which caſe, the perpendicular line of the ſaid teleſcope is converted into a horizontal line; which is the ſame with the line of *level*. The invention of this is owing to M. Caſſini.

LEVEL, *water*, that which ſhews the horizontal line by means of a ſurface of water, or other liquid; founded on this principle, that water always naturally places itſelf *level*.

The moſt ſimple is made of a long wooden trough, or canal, whoſe ſides are parallel to its baſe; ſo that being equally filled with water, the ſurface thereof ſhews the line of *level*. This is the chorobates of the ancients, deſcribed by Vitruvius, lib. viii. cap. 6.

This ſort of *level* is alſo made with two cups fitted to the two ends of a pipe three or four feet long, about an inch in diameter; by means whereof the water communicates from the one to the other cup: and this pipe being moveable on its ſtand, by means of a ball and ſocket, when the two cups become equally full of water, their two ſurfaces mark the line of *level*.

This inſtrument, inſtead of cups, may alſo be made with two ſhort cylinders of glaſs, three or four inches long, faſtened to each extreme of the pipe with wax, or maſtic. Into the pipe is filled ſome common or coloured water, which ſhews itſelf through the cylinders; by means whereof the line of *level* is determined: the height of the water with reſpect to the centre of the earth, being always the ſame in both cylinders. This *level*, though very ſimple, is yet very commodious for levelling ſmall diſtances.

LEVEL *of Mr. Huygens's Invention* conſiſts of a teleſcope, *A* (*Tab. Surveying fig.* 17.), in form of a cylinder; going through a ferril, in which it is faſtened by the middle. This ferril has two flat branches, *b b*, one above, and the other below; at the ends whereof are faſtened little moving pieces, which carry two rings, by one of which the teleſcope is ſuſpended to a hook at the end of the ſcrew 3; and by the other, a pretty heavy weight is ſuſpended, in order to keep the teleſcope in equilibrio. This weight hangs in the box 5, which is almoſt filled with ſtoned oil, oil of walnuts, or other matter that will not eaſily congulate, for more aptly ſettling the balance of the weight and teleſcope. The inſtrument carries two teleſcope, cloſe and very parallel to each other, the eye-glaſs of the one being againſt the object-glaſs of the other, that one may ſee each way without turning the *level*. In the focus of the object-glaſs of each teleſcope, muſt a little hair be ſtrained horizontally, to be raiſed or lowered as occaſion requires, by a little ſcrew. If the tube of the teleſcope, be not found level when ſuſpended, a ferril, or ring, 4, is put on it, and is to be ſlid along till it ſixes to a *level*. The hook on which the inſtrument is hung, is fixed to a flat wooden croſs; at the ends of each arm whereof there is a hook, ſerving to keep the teleſcope from too much agitation in uſing, or in carriage. To the ſaid flat croſs is applied another hollow croſs, that ſerves as a caſe for the inſtrument; but the two ends are left open, that the teleſcope may be ſecured from the weather, and always in a condition to uſe. The foot of this inſtrument is a round braſs plate, to which are faſtened three braſs ferrils, moveable by means of joints, wherein are put ſtaves: and on this foot is placed the box.

LEVELLING, the art or act of finding a line parallel to the horizon, at one or more ſtations, in order to determine the height of one place with reſpect to another; for the laying grounds even, regulating deſcents, draining moraſſes, conducting waters, &c.

One place is ſaid to be higher than another, or *out of level* with it, when it is more remote from the centre of the earth; and a line equally diſtant from the centre of it in all its points, is called the *line of true level*: whence becauſe the earth is round, that line muſt be a curve, and make a part of the earth's circumference, or an arch concentrical with it, as the line BCFG, *Tab. II. Surveying, fig.* 21. all the points whereof are equally diſtant from the centre of the earth *A*.

But the line of ſight, which the operations of levels give, is a tangent, or a right line perpendicular to the ſemidiameter of the earth; one extreme of which tangent being the point of contact, the other will be that of a ſecant drawn from the centre of the earth: and the point which determines it, will be above the ſurface of the earth, and of the true *level*, as much as that ſecant exceeds the radius, or ſemidiameter of the earth.

This extremity of the tangent is ſaid to be in the *apparent level*; as being that given by the ſight; but is eaſily reduced to the *true level*, becauſe we know, by trigonometry, how much each ſecant exceeds the radius; and becauſe, by meaſuring, we have diſcovered the preciſe length of that radius. Or, ſince the apparent *level* between the places B and C is BD, and the true *level* is the arc BC; it is plain that the former riſes above the latter by the line CD. But by a well-known property of the circle $2AC + CD \times CD = BD^2$, and the diameter of the earth being ſo great with reſpect to the line CD at all diſtances to which the operation of *levelling* commonly extends that 2 AC may be ſafely taken for 2 AC + CD without any ſenſible error, we ſhall have $2AC \times CD = BD^2$, and $CD = \frac{BD^2}{2AC}$ i.e. the difference between the true and apparent level is equal to the ſquare of the diſtance between the places divided by the diameter of the earth, or the riſe of the apparent above the true level is proportional to the ſquare of the diſtance. It was for want of the knowledge of this, that the ancients were not able to reduce the apparent level to the true one; and accordingly, to prevent falling into an error, never levelled above 20 feet at once, where ſuch reduction was not neceſſary.

By the table ſince made, it appears, that at the diſtance of 100 yards the apparent level is raiſed above the true one about one third of a line: ſo that the ancients, in this reſpect, were more ſcrupulous than needful. By means of this reduction, we are now able to level diſtances of one or two miles, at a ſingle operation, which the ancients could not do in leſs than three hundred.

The following table, for ſhewing the height of the apparent level above the true, was calculated by Mr. Ferguſon, to the extent of a whole degree of a great circle on the earth's ſurface; and it agrees ſo nearly with one of the ſame ſort in Dr. Long's Aſtronomy, as not to differ quite two inches therefrom at the end of the whole degree, which contains 60 geographical miles, equal to 69½ Engliſh miles. The uſe of this table is as follows:

If the quantity of an arc of a great circle on the earth's ſurface is given, in minutes or ſeconds of a degree, its meaſure may be found in feet and inches. Thus, ſuppoſe the arc contains 10 ſeconds, which is the ſixth part of a geographical mile, its meaſure is 1015 feet 8 inches. So an arc of one minute of a degree, which is one geographical mile, contains 6094 feet, or 2031 yards 1 foot; which is 171 yards 1 foot longer than an Engliſh mile. To find how far one can ſee in a true horizon (as at ſea) when the eye is raiſed to any given height above the horizon. Suppoſe the eye of an obſerver upon a ſhip at ſea to be 22 feet 2 inches above the ſurface of the water, he will then ſee 30470 feet all around him, or to the diſtance of 5 geographical miles.

Suppoſe the top of a mountain in the ſea to be ſeen at the diſtance of 60 geographical miles, or 1 degree, by an obſerver, whoſe eye is cloſe at the ſurface of the ſea; the height of that mountain is 3191 feet 1 inch, nearly, above the ſurface of the ſea. An Engliſh mile is 5280 feet, a geographical mile 6094.

Suppoſe a ſpring to be on one ſide of a hill, and a houſe on an oppoſite hill, with a valley between them; and that the ſpring, ſeen from the houſe, appears by a *levelling* inſtrument to be on a level with the foundation of the houſe, and is a mile from it; the apparent level of the ſpring is $10\frac{7}{10}$ inches above the true level of the houſe; and this difference would be ſufficient for the water to be brought in pipes from the ſpring to the houſe; the pipes being laid all the way in the ground.

If the diſtance of the object be greater than 60 minutes, or geographical miles, its height above the true level may be found thus. Suppoſe an eye at the ſurface of the ſea ſees the top of a mountain, which he knows to be 90 geographical miles, or a degree and a half, diſtant from him: take half that number of miles, and multiply the height of the apparent level above the true, anſwering to that half diſtance, by 4; and the product will give the perpendicular height of that mountain. Thus, the half of 90 is 45, againſt which (in the table) ſtands 1704 feet 11.763 inches; which being multiplied by 4, gives 7179 feet 11 inches for the perpendicular height of the mountain above the level of the ſea.

According to theſe meaſures, the earth's circumference is 131,650,400 feet, or 24,930 Engliſh miles.

At the diſtance of 1 ſecond of a degree (or $\frac{1}{60}$ of a geographical mile) the height of the apparent LEVEL above the true is .0020547 parts of an inch; at 2 ſeconds diſtance it is 4 times as much; at 3 ſeconds, 9 times; at 4 ſeconds, 16 times as much; and ſo on, always increaſing in proportion to the ſquare of the diſtance.

A TABLE shewing the height of the apparent level above the true, at any diſtance within a degree of a great circle on the earth's ſurface; calculated to the 1000th part of an inch.

60	6093	0,0	10,441	60	362640	58	9,435

To find the diſtance of any object from the place of the ſpectator by obſervation.

Meaſure a baſe line, and obſerve the angle which it ſubtends to the object, as directed in a great circle plus the earth, amounts to the height of the ſpectator's eye above the ſurface of the earth.

If the diſtance of the object from the place of the ſpectator be

Feet	Inches	Inches

the diſtance of the object from the place of the ſpectator is

which is reduced to a great circle plus the earth, amounts to the height of the ſpectator's eye above the ſurface of the earth.

Fergufou's Tables and Tracts, p. 243, &c. See DEPRESSION *of the horizon*.

The operation of *levelling* is as follows: ſuppoſe the height of the point A (*Tab.* II. *Surveying*, *fig.* 22), on the top of a mountain, above that of the point B, and at the foot thereof, required: place the level about the middle diſtance, between the two points, as in D, and ſtaffs in A and B; and let there be perſons inſtructed with ſignals for raiſing and lowering, on the ſaid ſtaffs, little marks of paſteboard, or other matter. The level being placed horizontally by the bubble, &c. look towards the ſtaff A E, and cauſe the mark to raiſed to be lowered, till the middle, upper edge, or other moſt conſpicuous part, appear in the viſual ray. Then meaſuring exactly the perpendicular height of the point E, above the point A, which ſuppoſe 6 feet 4 inches, ſet that down in your book: then turn the level horizontal about, that the eye-glaſs of the teleſcope may be ſtill next the eye when you look the other way (if you have only plain ſights, the inſtrument need not be turned); and cauſe the perſon at the ſtaff B to raiſe or lower his mark, till ſome conſpicuous part of it fall in the viſual ray, as at C; then meaſure the perpendicular height of C above B, which ſuppoſe 16 feet, 16 inches: ſet this alſo down in the book above the other number of the firſt obſervation; ſubtract the one from the other, the remainder will be ten feet four inches, which is the difference of level between A and B, or the height of the point A above the point B.

Note. If the point D, where the inſtrument is fixed, be in the middle between the two points A and B, there will be no neceſſity for reducing the apparent level to the true level; the viſual ray, in that caſe, being raiſed equally above the true level.

If it be further required to know whether there be a ſufficient deſcent for conveying water from the ſpring A, to the point B, *Tab.* II. *Surveying*, *fig.* 23.—Here, in regard the diſtance from A to B is conſiderable, it is required that ſeveral operations be made. Having then choſen a proper place for the firſt ſtation as at I, ſet up a ſtaff in the point A, near the ſpring, with a proper mark to ſlide up and down the ſtaff, as L; and meaſure the diſtance from A to I, which ſuppoſe 2000 yards. Then the level being adjuſted in the point I, let the mark L be raiſed and lowered till ſuch time as you ſpy ſome conſpicuous part of it through the teleſcope, or ſights of the level, and meaſure the height A L, which ſuppoſe 13 feet 5 inches. But in regard the diſtance A I is 2000 yards, you muſt have recourſe to your table for a reduction, ſubtracting 10 inches 3 lines, which will leave the height A L, 12 feet 6 inches 9 lines; and this note down in your book. Now turn the level horizontally about, ſo as the eye-glaſs of the teleſcope may be towards the ſtaff at A; and fixing up another ſtaff at H, cauſe the mark G to be moved up and down, till you ſpy ſome conſpicuous part through the teleſcope, or ſights. Meaſure the height H G, which ſuppoſe 6 yards, 4 feet, 2 inches. Meaſure likewiſe the diſtance of the points I H, which ſuppoſe 1300 yards; for which diſtance, according to the table, 4 inches 3 lines muſt be ſubtracted from the height H G, which conſequently will but leave 6 yards, three feet, 9 inches, 9 lines, to be taken down in your book.

This done, remove the level forwards to ſome other eminence, as E, whence the ſtaff H may be viewed; as alſo another ſtaff at D, near the place where the water is to be conveyed. The level being again adjuſted in the point E, look back to the ſtaff H; and managing the mark as before, the viſual ray will give the point F. Meaſure the height H F, which ſuppoſe 11 feet 6 inches. Meaſure likewiſe the diſtance H E, which ſuppoſe 1000 yards; for which diſtance the table gives 2 inches, 5 lines of abatement; which being taken from the height H F, there will remain 11 feet, 3 inches, 7 lines, which enter in your book. Laſtly, turning the level to look at the next ſtaff D, the viſual ray will give the point D. Meaſure the height of D from the ground, which ſuppoſe 8 feet, 3 inches. Meaſure alſo the diſtance from the ſtation E to B, which ſuppoſe 900 yards; for which diſtance the table gives 2 inches, 1 line of abatement; which being taken from the height B D, there will remain 8 feet, 11 lines, which enter as before.

For the manner in entering down obſervations in your book, obſerve that when a proper place or ſtation for the level, between the two points, has been pitched upon, you muſt write down the two heights obſerved at that ſtation, in two different columns, viz. under the firſt column, thoſe obſerved in looking through the teleſcope when the eye was from the ſpring, or towards the point, which we may call *back-ſights*; and under the ſecond column thoſe obſerved when the eye was next the ſpring, which we call *fore-ſights*, in the manner following:

Back-ſights.		Fore-ſights.	
	feet in. line.		*feet in. line.*
Firſt height	2 : 6 : 9	Second height	21 : 09 : 9
corrected	2 : 6 : 9	Fourth height	8 : 00 : 11
Third height	11 : 3 : 7		29 : 10 : 8
	23 : 10 : 4		

Having ſummed up the heights of each column ſeparately, ſubtract the leſſer from the greater, the remainder will be the difference of level between the points A and B; as in this example,

feet. inch. line.	
29 : 10 : 08	
23 : 10 : 04	
6 : 00 : 04	—The difference of height, or level, between the points A and B.

If the diſtance of the two points be required, add all the diſtances meaſured together; and dividing the difference of height by the yards of the diſtances; for each 200 yards you will have a deſcent of about 2 inches 9 lines. This problem may be otherwiſe ſolved in the following manner: let the *line f g*, *Tab.* II. *Surveying*, *fig.* 24, repreſent the line of ſight of the teleſcope, drawn from *f*, the interſection of the croſs-hairs, through *g* the centre of the object-glaſs; and the points *b*, *b*, be the marks on the glaſs tube or ſpirit level *a b c*. While theſe parts of the inſtrument are immutably fixed with reſpect to each other, it is manifeſt, that as often as the air-bubble is exactly reduced to the mark *b*, the line of ſight will be always reduced to the ſame poſition with reſpect to the horizon or to a plumb-line. Nor is it at all neceſſary in the buſineſs of *levelling* that the line of ſight and plumb line ſhould be exactly at right angles; but only that the angles they make ſhall be always the ſame. Let *p* and *q*, *fig.* 25, be two given points in two remote places and let it be required to find which is the lower and how much. Let *p a* and *q b* repreſent two ſtraight ſtaffs or poles fixt upright, by means of a plumb-line. Having placed

placed the telescope by the side of the pole $p\,a$, and directed the line of sight to the pole $q\,b$, after its elevation by the screw adapted to this purpose, till the air-bubble rests exactly at the marks upon the tube. Then let an assistant mark the point b, which appears to be covered by the cross hairs; and also the point a exactly upon a level with the cross hairs; which is easily done by a common square applied to the side of the pole $p\,a$. Then remove the telescope to the pole $b\,q$, and here let the same things be repeated; that is, let d be the place upon a level with the cross hairs, and c the point upon the other pole $p\,a$, that appears to be covered by them while the air-bubble rests at the same mark as before. Bisect the interval $a\,c$ in g, and the interval $b\,d$ in h, and the points g, h will be upon a level; that is, if we suppose $g\,p\,q\,h$ to represent a long canal full of stagnating water, the points g, h will both be in its surface; and consequently taking the lesser depth $p\,g$ from the greater $q\,h$, their difference $q\,r$ shews how much the point q is below the point p or r.

If the places p, q cannot be seen from each other, or if the difference of their heights be greater than the length of any common poles, then one or more intermediate stations must be chosen; and by repeating the same practice between every two successive stations, we shall find the level of the extremes.

When the points g, h are once found upon two poles not far asunder, it will be convenient by moving the cross-hairs, to rectify the line of sight, so as to be nearly coincident with the line $g\,h$, or with a line parallel to it; for then in future levellings, at greater distances, the marks b, c will be less subject to fall above or below the poles.

This reciprocal way of levelling seems to be the most exact of any, especially if it be performed by two instruments made to agree together beforehand; which may be done by placing them together, and by altering the cross hairs in either of them, till the same mark upon a remote object is covered by both the crosses, while both the bubbles rest at their marks upon the tubes. Then may two observers find the marks upon the opposite poles at the same time; and consequently the refractions of the rays in the air, whatever be their quantities, will be equal as near as possible; and then the result of the practice will be as accurate as if there had been no refractions at all. For let the curve $b\,i\,o$ *fig.* 26, represent the course of the visual ray from b to a, and let the lines $a\,b$, $b\,t$ touch it at a and b. Then because the points a, b are very nearly upon a level, the density and constitution of the air and vapours at the same instant will be nearly the same in each place; and by consequence the curve $a\,i\,b$ and its tangents at a and b, will be equally inclined to the chord $a\,b$. For the same reasons the curve $e\,m\,d$ will be similar and equal to the curve $a\,i\,b$, being situated so very near to it. Therefore the angle $e\,d\,n$, under the chord $e\,d$ and tangent $d\,n$, will be equal to the angle $a\,b\,t$ or $b\,a\,b$; and consequently since the angles $q\,d\,n$, $p\,a\,t$ are made equal in the two observations, by taking away the equal angles $e\,d\,n$, $b\,a\,t$, caused by the equal refractions, the remaining angles $q\,d\,e$, $p\,a\,b$ will be equal to each other, as if there were no refractions at all.

If the reciprocal observations be made about the middle of the same day, when the air is the purest, there will scarce be any occasion for two instruments; but if they be made near the morning or evening, even on the same day, an equality of refractions cannot be depended upon, unless they are made at the same instant. The members of the Royal Academy of Sciences at Paris tell us, in their account of the Measure of the Earth, they often found, that an object which at break of day appeared in the level, and sometimes a little above it, did afterwards, when the sun was up, appear below it. And on the contrary, after the setting of the sun, objects far distant appeared to be raised so sensibly, that in less than half an hour their apparent height was augmented more than three minutes. As to the cause of these appearances they add, that the coolness of the night condenses the vapours, which descend to a lower place, leaving the air in the higher stations more pure than in the day time. And, on the contrary, when the heat of the sun has made a part of the vapours to mount to more elevated stations, there must be less difference of the mediums, and consequently a less refraction.

Setting aside the curvity of a ray, which Mr. Picard tells us is scarce sensible about noon, when the distance of the object does not exceed 1000 toises, the line of sight through the telescope may be set perpendicular to a plumb-line or parallel to the horizon in this manner. Having found two points g, h, *fig.* 27, upon a level as before, let $g\,i$ be perpendicular to $g\,c$ and cut $c\,h$ in i, and having computed the line $b\,i$ (as follows) and made a mark at i, place the level at g and alter the place of the cross hairs in the focus, till they appear to cover the point i when the air-bubble is at its marks, and the business is done. Now the line $b\,i$ is equal to the square of $g\,b$ applied to $2\,g\,c$, and consequently may be found by measuring the distance $g\,b$, and dividing its square by the diameter of the earth, which may be supposed equal to $2\,c$, though it is not exactly so, the earth being not exactly spherical. For bisecting $g\,b$ in k, draw $c\,k$ cutting $g\,i$ in l; and since the triangles $l\,g\,i$, $k\,g\,c$ are similar, we have $c\,k : k\,g :: g\,i : g\,l$, and by doubling them all, we have $b\,i : g\,b :: g\,b : 2\,k$. Mr. Picard computes that when the distance $g\,b$ is 300 toises or 1800 Paris feet, the line $b\,i$ is one inch; and hence any other $b\,i$ may be found for any other known distance; it being as the square of the distance $g\,b$.

Hence when the instrument is thus rectified, the point b upon the level with g, may be found by one observation; that is by marking the point i covered by the cross hairs, and by computing $i\,b$ by the rule above. As the intervals between the stations must be but small in this method, because of refractions, as was said above, the readiest way is to make them all equal; which may be known exact enough for this purpose, by observing whether the pole be removed to such a distance, that its image (or the image of any given part of it) in the focus of the telescope shall be always of the same length, being measured by the distance between two parallel hairs in the focus: and then the same allowance must always be made for the depth of the point b below i.

Lastly, by means of these parallel hairs, it is easy to find when the telescope is placed in the middle between two stations; and then the points upon a level at each pole are presently found, by directing the telescope first to one pole and then to the other, and by marking the points covered by the cross hairs. And these points will be upon a level, notwithstanding any refractions of the visual rays, because the refraction of each ray will be equal. Smith's Optics, book iii. chap. 14.

Dr. Halley suggests a new method of *levelling*, which has been put in practice by some of the French academy: this is performed wholly by means of the barometer, in which the mercury is found to be suspended to so much the less height as the place is farther remote from the centre of the earth. Hence it follows, that the different heights of the mercury, in two places, give the difference of level.

Mr. Derham, from some observations he made at the top and bottom of the Monument, found that the mercury fell one tenth of an inch at every 82 feet of perpendicular ascent, when the mercury was at 30 inches. Dr. Halley allows of one tenth of an inch for every 30 yards; which, considering how accurately the barometers are now made, an inch, in some of them, being divided into an hundred, or more parts, all very sensible, he thinks this method sufficiently exact to take the levels for the conveyance of water, and less liable to errors than the common levels.

The same author found a difference of three inches eight tenths, between the height of the mercury at the top and bottom of Snowdon-hill in Wales.

Mr. Ferguson has calculated the following table, for shewing how much the mercury would sink in a barometer at given heights above the earth's plane surface; and consequently, how the perpendicular height of any hill may be found thereby.

At the height of	Mercury sinks	At the height of	Mercury sinks	At the height of	Mercury sinks	At the height of	Mercury sinks

By this table, and a common barometer tube, the perpendicular height of any hill may be found in the following manner.

The lower end of the tube being immersed in quicksilver in the common way, and the tube fixed to a board, let a scale, eighteen inches in length, be divided into inches, and each inch into a hundred equal parts, by diagonal lines, the divisions to be numbered downward from the top. This scale must be made to slide in a groove on the board, and have a cross index to slide upon it to any division.

Then, at the bottom or foot of the hill, place the scale so as the beginning of the divisions at its top may be just even with the top or surface of the mercury in the tube. This done, carry the machine up to the top of the hill; then set the index to the surface of the mercury, and it will shew how much the mercury has sunk in the tube, at the top of the hill, from the point where it stood when at the bottom; and the number of feet expressed in the table, against the like sinking of the mercury, will be the perpendicular height of the hill.

Thus, supposing the mercury has sunk 8 inches and 3 hundredth parts of an inch, the height of the hill must be 8500 feet, or a mile, and somewhat more than a quarter. Proportionable allowance is easily made for intermediate heights in the table, which are only to whole hundredths of feet.

Mr. Dentam found the difference of height of the mercury at the bottom and top of Snowdon-hill in Wales to be 3 inches 8 tenths (the same as 3 inches 80 hundredths) it shews that the height of that hill is 3700 feet or almost three quarters of a mile.

N. B. 660 feet make an eighth part of a mile, 1320 feet a quarter of a mile, 2640 feet half a mile, 3960 feet three quarters of a mile, and 5280 feet make a whole mile. See BAROMETER and ATMOSPHERE.

Dr. Desaguliers contrived an instrument, by which the difference of level of two places, which could not be taken in less than four or five days with the best telescope levels, may be taken in a few hours. The instrument is as follows:

To the ball C (*Tab.* II. *Surveying*, *fig.* 28.) is joined a recurved tube B A, of a very fine bore, with a small bubble at the top A, whose upper part is open. From the construction of this instrument, it is evident, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and the tube, when the instrument is set upright. If the air at C be so expanded by heat, as to drive the liquor to the top of the tube, the cavity A will receive the liquor, which will come down again, and settle at D, or near it, according to the level of the place where the instrument is, as soon as the air at C returns to the same temperament as to heat and cold. For preserving the same degree of heat, when the different observations are made, the machine is fixed in a tin vessel, E F, filled with water up to *g h*, above the ball, and a very sensible thermometer has also its ball under water, that one may observe the liquor at D, in each experiment, when the liquor in the thermometer stands at the same height as before. The water is poured out when the instrument is carried, which may be done conveniently by means of the wooden frame, (*fig.* 29.) which is fet upright by three screws, S, S, S, and a line and plummet P P (*fig.* 30.) At the back part of the wooden frame (*fig.* 31.) from the piece at top, K, hangs the plummet P, over the brass point at N. M, *n*, are brackets for keeping the upright board, K N, at right angles with the horizontal one at N. The machine seen in front is represented *fig.* 32. supporting the fore part of the tin vessel transparent; and here the brass socket of the recurved tube, into which the ball is screwed, has two wings at I I, fixed to the bottom, that the ball may not break the tube by its endeavour to emerge, when the water is poured in as high as *g h*.

After Dr. Desaguliers had contrived this machine, he considered, that as the tube is of a very small bore, if the liquor should rise into the ball at A (*fig.* 28.) in carrying the instrument from one place to another, some of it would adhere to the sides of the ball A, and upon its descent in making the experiment, so much might be left behind, that the liquor would not be high enough at D, to shew the difference of the level; therefore, to prevent that inconveniency, he contrived a blank screw, to shut up the hole at A, as soon as one experiment is made, that in carrying the machine, the air in A may balance that in C, so that the liquor shall not run up and down the tube, whatever degree of heat and cold may act upon the instrument in going from one place to another. Now because one experiment may be made in the morning, and the water may be so cold, that when a second experiment is made at noon, the water cannot be brought to the same degree of cold it had in the morning; therefore, in making the first experiment, warm water must be mixed with the cold, and when the water has stood some time before it comes to be as cold as it is likely to be at the warmest part of that day, observe and set down the degree of the thermometer at which the spirit stands, and likewise the degree of the water in the barometer at D; then screw on the cap at A, pour out the water, and carry the instrument to the place whose level you would know; then pour in your water, and when the thermometer is come to the same degree as before, open the screw at top, and observe the liquor in the barometer.

The doctor's scale for the barometer is ten inches long, and divided into tenths; so that such an instrument will serve for any heights not exceeding ten feet, each tenth of an inch answering to a foot in height.

The doctor made no allowance for the decrease of density in the air, because he did not propose this machine for measuring mountains (though with a proper allowance for the decreasing density of the air, it will do very well), but for heights to be known in gardens, plantations, and the conveyance of water; where an experiment that answers to two or three feet in a distance of twenty miles, will render this a very useful instrument. Desaguliers' Exp. Phil. vol. ii. p. 372, &c.

For the common occasion of *levelling* to be performed without much apparatus of instruments, time or trouble, the following method may serve: set a pole upright in a spring, pond, river, or other place, whence water is to be brought, and mark how many feet, and inches, are above water. Then set up another pole, of equal length with the other, in the place to which the water is to come. Place the centre of a quadrant on the top of this last pole, the plummet hanging freely; spy through the sights the top of the pole that is in the water, and if the thread cuts any degree of the quadrant, the water may be conveyed by a pipe laid in the earth. If you cannot see from one extreme to the other, the operation may be repeated in the manner already directed.

LEVEL-*range*. See HORIZONTAL *range*.

LEVEL-*staves*, are instruments used in *levelling*; serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist each of two long square wooden rulers, made to slide over one another, and divided into feet, inches, &c.

LEVEN, in *Natural History*, a term used by Boccone for the milky juice contained in the globules placed at the tops of the stalks of red coral. These round buttons are the only part of the coral, which are soft while under water, and from these the milky juice is easily expressed by a gentle squeezing between the fingers. The globules are each made up of five or six little cells, not communicating with one another, and each containing its own separate quantity of this white and thick fluid. When the coral is newly taken up out of the sea, this juice is of a sharp, acrimonious and astringent taste; but when it has been some time exposed to the air, it loses the acrimony, and the astringency of the taste only remains. This change in the taste is made in six or eight hours, in hot weather, and the juice, in the same time, loses its colour and consistence, growing hard and brown. Philos. Trans. N° 100.

LEVER, or LEAVER, in *Mechanics*, an inflexible straight bar, supported in a single point or on a fulcrum, or prop, and used for the raising of weights.

The

The word is formed of the French *levier*, which fignifies the fame; formed of the verb *lever*, or Latin *levare*, *to raife*.

The *lever* is the firft of thofe called mechanical powers, or fimple machines, as being, of all fuch, the moft fimple; and is chiefly applied for raifing weights to fmall heights.

In a *lever* there are three things conſidered: the weight to be raiſed, or ſuſtained, as O (*Tab. Mechanics, fig.* 1.) The power by which it is to be raiſed, or ſuſtained, as B. And the fulcrum or prop, D, whereon the *lever* is ſuſtained, or rather on which it moves round, the fulcrum remaining fixed.

Levers are of three kinds; ſometimes the fulcrum or centre of motion is placed between the weight and the power, as in *fig.* 1. this we call a *lever of the firſt kind*, or ceſtis DIEPHONOUNTOS; to which may be reduced ſciſſars, pincers, ſnuffers, &c. ſometimes the weight is between the fulcrum and the power, which is called a *lever of the ſecond kind*, as in *fig.* 2. Of this kind are the oars and rudder of a boat, the moſts of ſhips, cutting knives fixed at one end, and doors whoſe hinges are as the fixed point. And ſometimes the power acts between the weight and the fulcrum, which is the *lever of the third kind*. Such is a ladder lifted by the middle to reſt it up againſt a wall; theſe two are called ceſtes HOMOMOUNOI.

In this laſt, the power muſt exceed the weight in proportion as its diſtance from the centre of motion is leſs than the diſtance of the centre from the weight. And as the firſt two kinds of *lever* ſerve for producing a ſlow motion by a ſwift one, ſo the laſt ſerves for producing a ſwift motion of the weight by a ſlow motion of the power. It is by this kind of *levers* that the muſcular motions of animals are performed, the muſcles being inſerted much nearer to the centre of motion than the point where the centre of gravity of the weight to be raiſed is applied; ſo that the power of the muſcle is many times greater than the weight which it is able to ſuſtain. Though this may appear at firſt ſight a diſadvantage to animals, becauſe it makes their ſtrength leſs; it is, however, the effect of excellent contrivance: for if the power was, in this caſe, applied at a greater diſtance than the weight, the figure of animals would be not only awkward and ugly, but altogether unfit for motion; as Borelli has ſhewn in his treatiſe De Motu Animalium. The power of the *lever* is founded on the following theorem; viz. "That the ſpace, or arch, deſcribed by "each point of a *lever*, and conſequently the velocity "of each point of a *lever*, is as its diſtance from the "fulcrum, or prop."

From hence it follows, that the action of a power, and the reſiſtance of the weight, increaſe in proportion to their diſtance from the fulcrum.

And hence alſo it follows, that a power will be able to ſuſtain a weight, if the diſtance of the point in the *lever* to which it is applied, be to the diſtance of the weight, as the weight to the intenſity of the power; which, if it be ever ſo little increaſed, muſt raiſe the weight. See this doctrine demonſtrated under the word MECHANIC *Powers*; and farther illuſtrated under the word BALANCE; between which, and the *lever*, there is a great analogy; a *lever* of the firſt kind being a ſort of beam to raiſe weights.

The power and action of the *lever* will be fully illuſtrated by the following propoſitions:

1. If the power applied to a *lever* of any kind ſuſtain a weight, the power is to the weight in a reciprocal ratio of their diſtances from the fulcrum.

2. The weight of a *lever* of the firſt or ſecond kind A B, *fig.* 1. the diſtance of the centre of gravity from the fulcrum C V, and the diſtances of the weight, and the power A C and C B, being all given, to find the power that will ſuſtain it. Suppoſe the *lever* void of gravity, but in lieu thereof a weight hung at V; if then A C be made to C V, as the gravity of the *lever* to a fourth number, we ſhall have the weight which the *lever* is able to ſuſtain; and this ſubtracted from the given weight, the remainder will be the weight to be ſuſtained by the power. Let C B then be to C A, as the remaining weight to a fourth weight, and we ſhall have the power to be applied in B, in order to ſuſtain the given weight with the given *lever*.

3. The gravity of a *lever* of the firſt or ſecond kind A B, the diſtance of the centre of gravity from the fulcrum C V, the diſtances of the power, and the weight B C and C A, being all given, to find the weight to be ſuſtained. Find the part of the weight ſuſtained by the *lever* alone, as in the former problem: in the ſame manner find the other part of the weight, which the power applied in B is able to ſuſtain; and the two numbers together, and the ſum is the weight required.

4. The gravity, and centre of gravity F, of a *lever* of the ſecond kind C B, *fig.* 2. with the weight G, its diſtance from the fulcrum C A, and from the power C B being given, to find the power capable of ſuſtaining the weight. Suppoſe the *lever* void of gravity, but in lieu thereof a weight equal thereto hung in F, the power required to ſuſtain the *lever* alone; then find the power requiſite to ſuſtain the given weight G; add the powers together, and the ſum will be the power required.

5. If a power applied to a *lever* of any kind laſt a while, the ſpace of the firſt is to that of the laſt, as is this laſt to a power able to ſuſtain the ſame weight; whence it follows, that the gain of force is always attended with the loſs of time, and *vice verſâ*.

When the two arms of a *lever* are not in a right line, but contain any invariable angle at C (*Tab.* IV. *Mechanics, fig.* 49.) the *lever* is called a bended *lever*; and is evidently of the firſt kind, and the law of the equilibrium is the ſame; i. e. if the power P be applied at B to the arm C B, and the weight W acts by means of a pulley M, in the direction A M, perpendicular to the arm A, the power and weight will ſuſtain each other, if P be to W, as C A to C B, or P × C B = W × C A. If ſeveral powers act upon the arm C A, find their centres of gravity, A, on the arm C A, and ſuppoſe all the powers to be united there; and if the power P be to their ſum as C A to C B, it will ſuſtain them. The ſum of the powers being given, it is manifeſt that the farther their centre of gravity A is removed from the centre of motion C, the greater reſiſtance they will oppoſe againſt the power P, and it will require the greater force in the power to overcome them. Hence Galileo juſtly concludes, that the bones of animals are the ſtronger for their being hollow, their weight being given; as if the arm C B F repreſents their length, the circle C H D a ſection perpendicular to the length, P any power applied along their length, tending to break them; then the ſtrength or force of all their longitudinal fibres, by which the adheſion of the parts is preſerved, may be conceived to be united in A, the centre of the circle C H D, which is the common centre of gravity of thoſe forces, whether the ſection be a circle or annulus. But it is plain that when the area of the ſection, or the number of ſuch fibres is given, the diſtance C A is greater when the ſection is an annulus than when it is a circle without any cavity; conſequently the power with which the parts adhere, and which reſiſts againſt P, that endeavours to ſeparate them, is greater in the ſame proportion. For the ſame reaſon, the ſtalks of corn, the feathers of fowls, and hollow ſpears, are leſs liable to accidents that tend to break them than if they were of the ſame weight and length, but ſolid, without any cavity. In this inſtance, ſays Mr. Maclaurin, (View of Sir I. Newton's Phil. Diſc. book ii. chap. 3. § 134.) art only imitates the wiſdom of nature.

LEVERET, among *Sportſmen*, a young hare, in the firſt year of its age.

LEVIGATION, the reduction of hard and ponderous bodies, as coral, tutty, precious ſtones, &c. into a fine fubtil powder, by grinding them with water upon porphyry, or the like, as painters do their colours.

Levigation is much uſed in pharmacy and chemiſtry; but unleſs the grinding inſtruments be extremely hard, they will wear away, ſo as ſometimes to double the weight of the medicine thus managed.

LEVIRATE, in the *Jewiſh Cuſtoms*, a term uſed by authors who have written on the law and cuſtoms of the Jews, to denote particularly that law of Moſes, which obliges one brother to marry the widow of another, who died without children, to raiſe up ſeed to him.

The word is derived from *levir*, which fignifies, in Latin, the huſband's brother, or the brother-in-law; and the word *levirate* has been hence formed, to expreſs the law whereof we have been ſpeaking.

This law, which is an exception to that which condemns marriages between brothers and ſiſters, and between brothers-in-law and ſiſters in-law, ſeems to have been in uſe among the Hebrews and Canaanites before the time of Moſes; ſince Judah gave his firſt-born Er, and Onan his ſecond ſon, ſucceſſively to Tamar, and obliges himſelf to give her likewiſe to Selah his third ſon. Calm. Dict. Bibl.

LEVISTICUM, in *Botany*, a name given by ſome to *liguſticum*, or LOVAGE.

LEVITE, an inferior kind of miniſter in the Jewiſh tabernacle and temple, who had the care and management of the ſacred utenſils.

The word comes from the Greek ΛΕΥΙΤΗΣ, the root of which is the name *Levi*; which was given to that patriarch by his mother Leah, from the Hebrew ווֹלִי, *lavah*, *to be tied*, or *united*; Leah hoping, by the birth of this ſon, to be more cloſely linked to her huſband Jacob; and, therefore, in a large ſenſe, the *Levites* were the poſterity of this patriarch, and conſtituted one of the twelve tribes of Iſrael. But the ſons of Levi were appointed to this office, in conſequence of the extraordi-

nary

nary zeal they diſcovered againſt idolatry, in the caſe of the golden calf. Exod. xxxii. 26. 28. They were originally divided into three claſſes or families, from the three ſons of *Levi*, Kohath, Gerſhon, and Merari, but afterwards by David into twenty-four courſes.

The *Levites*, in the Jewiſh church, were an order inferior to the prieſts; and anſwered, in ſome meaſure, to deacons, in the Chriſtian church.

The *Levites* of the old law had no ſettled lands allotted them for their maintenance, as the other tribes had, but lived chiefly on the offerings made to God. They were diſtributed through all the tribes, each of which gave ſome of their cities to the *Levites*, amounting in all to the number of thirty-five, with grounds in their neighbourhood for the ſubſiſtence of their flocks. In the weeks of their attendance at the ſanctuary, they were maintained by the dues ariſing from the ſacrifices; beſides theſe dues, the firſt-fruits, which were brought to the temple, and the money paid for the redemption of the firſt born, contributed to their ſubſiſtence. But their maintenance chiefly aroſe from the tithes of the produce of the whole country, which was the law allotted to the tribe of Levi, Numb. xviii. 21. a tenth of which they paid to the prieſts.

According to the numeration made by Solomon, from the age of twenty there were thirty-eight thouſand *Levites* capable of ſerving; twenty-four thouſand of theſe he appointed for the daily miniſtry under the prieſts, ſix thouſand to be inferior judges in the cities and to decide matters relating to religion, and of no great conſequence to the ſtate; four thouſand to be door-keepers, and to take care of the riches of the temple; and the reſt to do the office of chanters, or ſingers.

LEVITICI, in *Church Hiſtory*, a ſect of heretics, who ſprung from the Gnoſtics and Nicolaitans.

LEVITICUS, a canonical book of the Old Teſtament, ſo called from its containing the laws and regulations relating to the prieſts, Levites, and ſacrifices.

LEVITY, the privation or want of weight in any body, when compared with another that is heavier.

In which ſenſe, *levity* ſtands oppoſed to GRAVITY.

The ſchools maintain, that there is ſuch a thing as *poſitive*, and *abſolute levity*, and impute to this the riſe or emergency of bodies lighter in ſpecie than the bodies wherein they riſe:

But we find by experience, that all bodies tend towards the earth, ſome ſlower, and ſome faſter, in all fluids, or mediums, whether water, air, &c. Thus, cork is only ſaid to be lighter than gold, becauſe, under equal dimenſions, the gold will ſink in, and the cork ſwim upon water.

Archimedes has demonſtrated, that a ſolid body will float any where in a fluid of the ſame ſpecific gravity; and that a lighter body will keep above a heavier. The reaſon is, that of bodies falling towards the earth, thoſe which have a like number of equal parts, have equal gravity; ſince the gravity of the whole is the ſum of the gravity of all its parts. Now two bodies have an equal number of equal parts, if under the ſame dimenſions there be no intervals deſtitute of matter; whence it follows, that as no portion of matter is ſo ſmall, but that the body wherein it is contained may be wholly divided into parts equally ſmall, there can be no reaſon for the deſcent of thoſe, which will not equally hold for the deſcent of that.

Hence it may be concluded, that thoſe bodies which do not equally gravitate under the ſame dimenſions, do not contain equal portions of matter; and, therefore, when we ſee, that a cube of gold ſubſides in water at the ſame time that an equal bulk of cork ſwims upon it, it is evident, that the gold muſt have a greater number of equal parts of matter, under the ſame bulk, than the cork; or the cork muſt have a greater number of vacuities than the gold; and that there is alſo in the water a greater number of vacuities than in gold. See FLUIDS, and *Specific* GRAVITY.

Hence we have a clear idea both of denſity or gravity, and of *levity*; and know, that the latter cannot, in a ſtrict ſenſe, be accounted any thing poſitive, but only a mere negation, or abſence, of body; which determines that body to be lighter than another which contains more matter.

Dr. Hook, it is true, ſeems to maintain ſomething like a poſitive *levity*; which, if we miſtake not, is what he means by the term *levitation*; viz. a property of bodies directly contrary to that of gravitation towards the ſun.

This, he thinks, he has diſcovered in the ſtreams of ſeveral comets; which, though they had a deſcent from the nucleus of the comet towards the ſun, yet they quickly returned, and went oppoſite to the ſun, and that to a prodigious extent. In effect, where the power of gravitation ceaſes, it ſhould ſeem ſome ſuch contrary force does begin; whereof we have inſtances in the phenomena of attraction. This is what ſir Iſaac Newton calls the *vis repellens*, and appears to be one of the laws of nature; without which it would be hard to account for rarefaction and ſome other appearances.

LEVY, *levare*, in *Law*, ſignifies to gather, or collect; as to *levy* money, to *levy* troops, &c.

LEVY ſometimes alſo denotes to erect, or ſet up; as, to *levy* a mill. *Levy* alſo ſignifies to raiſe or caſt up; as, to *levy* a ditch. To *levy* a fine of lands, is to paſs a *fine*.

LEWDNESS is puniſhable by our law by fine, impriſonment, &c. And Mich. 15 Car. II. a perſon was indicted for open *lewdneſs*, in ſhewing his naked body in a balcony, and other miſdemeanors, and was fined two thouſand marks, impriſoned for a week, and bound to his good behaviour for three years. 1 Sid. 168. In times paſt, when any man granted a leaſe of his houſe, it was uſual to inſert an expreſs covenant, that the tenant ſhould not entertain any lewd women, &c. See BAWD, INCEST, &c.

LEWING, in *Metallurgy*, the ſifting the ores of metal in water. This is done in fine ſieves moved backward and forward under water; and this is the method of ſeparating the finer parts of the ores which had ſubſided among the larger lumps, under that part of it ſeparated for uſe in the various waſhings. The coarſer matter, left in the ſieve, is powdered again with the larger maſſes, and all thus ſifted together for the blowing-houſe.

LEX, *Law*. See LAW.

LEX *amiſſa*, or *legem amittere*, in *Law*, is underſtood of an infamous, perjured perſon, who is ſaid to *loſe his law*; or, as Bracton has it, *non eſt uſurus ſignus legis*. See INFAMOUS.

LEX *judicialis*, is properly *purgatio, per judicium ferri*; ſometimes called ſimply JUDICIUM.

LEX *ſacramentalis*, *purgatio per ſacramentum*. See OATH, and PURGATION.

LEX *talionis*. See TALIO.

LEX *terræ*, the law and cuſtom of the land; by which name it is diſtinguiſhed from the *civil law*. See COMMON *law*.

LEGEM *terræ amittere*. See AMITTERE.

LEXIARCHI, Λεξιαρχοι, at Athens, ſix officers, aſſiſted by thirty inferior ones, whoſe buſineſs it was to lay fines upon ſuch as came not to the public aſſemblies, and alſo to make ſcrutiny among ſuch as were preſent.

The *lexiarchi* kept a regiſter of the age, manners, and abilities of all the citizens, who were always enrolled at the age of twenty.

LEXICON, Λεξικον, the ſame with dictionary.

The word is chiefly uſed in ſpeaking of Greek dictionaries: it is derived from the Greek λεξις, *word, diction*; of λεγω, *I ſpeak*.

LEY. See LIXIVIUM.

LEYDEN *phial*, in *Electricity*, is a glaſs phial or jar coated both on the inſide and outſide with ſome conducting ſubſtance, for the purpoſe of being charged, and employed in a variety of entertaining and uſeful experiments. See COATING and CHARGE.

It was thus called becauſe Mr. Cunæus, a native of Leyden, was ſuppoſed to have firſt contrived, about the cloſe of the year 1745, to accumulate the electrical power in glaſs by this method; and hence the operation of charging and diſcharging coated glaſs, in general, has been denominated the *Leyden* experiment; and a vacuum produced in a jar of this kind has been called the *Leyden vacuum*. But Dr. Prieſtley, the hiſtorian of electricity, informs us, that the perſon who firſt made this great diſcovery was Mr. Von Kleiſt, dean of the cathedral in Camin; who, on the fourth of November, 1745, ſent an account of it to Dr. Leiberkuhn at Berlin: however, thoſe, to whom Mr. Kleiſt's account was communicated, could not ſucceed in performing his experiments. The views which led to this diſcovery in Holland are ſtated by Dr. Prieſtley in the following manner: profeſſor Muſchenbroek and his friends, obſerving, that electrified bodies, expoſed to the common atmoſphere, which is always replete with conducting particles of various kinds, ſoon loſt their electricity, and were capable of retaining but a ſmall quantity of it, imagined, that if the electrified bodies were terminated on all ſides by original electrics, they might be capable of receiving a ſtronger power, and retaining it a longer time. Glaſs being the moſt convenient electric for this purpoſe, and water the moſt convenient non-electric, they firſt made theſe experiments with water in glaſs bottles; but no conſiderable diſcovery was made, till Mr. Cunæus, happening to hold his glaſs veſſel in one hand, containing water, which had a communication with the prime conductor by means of a wire; and with the other hand diſengaging it from the

the conductor, when he imagined the water had received as much electricity as the machine could give it, was surprised by a sudden shock in his arms and breast, which he had not in the least expected from the experiment. This experiment was repeated, and the first account of it published in Holland by Mr. Allamand and Mr. Muschenbroeck; by the abbe Nollet, and M. Sonnier, in France; and by Messrs. Grabath and Runger, in Germany. Mr. Grabath contrived to increase the strength of the shock, by altering the shape and size of the phial, and also by charging several phials at the same time, so as to form what is now called the *electrical* BATTERY. He likewise made the shock to pass through a number of persons connected in a CIRCUIT from the outside to the inside of the phial. He observed, that a cracked phial would not admit of being charged; and he discovered what is now called the RESIDUUM *of a charge*. Dr. Watson, about this time, observed a circumstance attending the operation of charging the phial, which, if pursued, would have led him to the discovery, which was afterwards made by Dr. Franklin. He says, that when the phial is well electrified, and you apply your hand to it, you see the fire flash from the outside of the glass, wherever you touch it, and it crackles in your hand. He also observed, that when a single wire only was fastened round a phial, properly filled with warm water, and charged, upon the instant of its explosion, the electrical corruscations were coming out from the wire, and to illuminate the water contained in the phial. He likewise found, that the shock in the discharge of the phial was *entirely farther*, as the points of contact of the non-electrics of the outside of the glass, which led to the ends of COATING glass in consequence of which he made experiments, that led him to conclude, that the effect of the *Leyden* bottle was greatly increased, if it was not principally owing to, not so much the quantity of non-electric matter contained in the glass as the number of points of non-electric contact within the glass, and the density of the matter of which those points consisted; provided the matter was, in its own nature, a ready conductor of electricity. He farther observed, that the explosion was greater from hot water inclosed in glasses, than from cold, and from his coated jars, warmed, than cold. For his manner of explaining the shock of the *Leyden* phial, see ARTIFICE.

Mr. Wilson, in 1746, discovered a method of giving the shock to any particular part of the body, without affecting the rest; he also increased the strength of the shock by plunging the phial in water, thereby giving it a coating of water on the outside as high as it was filled on the inside; he likewise found, that the law of accumulation of the electric matter in the *Leyden* bottle was always in proportion to the thinness of the glass, the surface of the glass, and that of the non-electrics in contact with the inside and outside thereof. Mr. Wilson made a variety of other experiments with the *Leyden* phial, which our limits will not allow us to recite.

Mr. Canton found, that if a charged phial was placed upon electrics, the wire and the coating would give a spark or two alternately; and that, by continuing this operation, the phial would be discharged; though he did not observe that the se alternate sparks proceeded from the two contrary electricities discovered by Dr. Franklin.

The abbe Nollet made several experiments with this phial. He received a shock from a bottle, out of which the air had been exhausted, and into which the end of his conductor had been inserted. He ascribed the force of the glass in giving a shock, to that property of it, whereby it retained it more strongly than conductors do, and was not so easily divested of it as they are. He also first tried the effect of the electric shock on brute animals, and enlarged the CIRCUIT of its conveyance.

M. Monnier is said to have been the first who discovered that the *Leyden* phial would retain its electricity for a considerable time after it was charged, and to have found it to do so for thirty-six hours, in time of frost; and it is remarkable, that the French as well as English philosophers made several experiments, which, with a little greater degree of attention, would have led them to the discovery of the different quality of the electricities on different sides of the glass. But this was reserved for the ingenious doctor Franklin, who, in explaining the method of charging the *Leyden* phial, observes, that when one side of the glass is electrified positively, or *plus*, the other side is electrified negatively or *minus*; so that whatever quantity of fire is thrown upon one side of the glass, the same is thrown out of the other; and if a phial not charged, none can be thrown into the inside, when none can be got out from the outside; and there is really no more electric fire in the phial after it is charged than before; all that can be done by charging being to take from one side, and convey to the other. Dr. Franklin also observed, that glass was impervious to electricity; and that, therefore, since the equilibrium could not be restored to the charged phial by any internal communication, it must be done by conductors externally joining the inside and the outside. These capital discoveries he made by observing, that when a phial was charged, a cork-ball, suspended on silk, would be attracted by the outside coating, when it was repelled by a wire communicating with the inside, and vice versa. But the truth of this maxim appeared more evident, when he brought the knob of the wire communicating with the outside coating within a few inches of the wire communicating with the inside coating, and suspended a cork ball between them; for, in that case, the ball was attracted by them alternately, till the phial was discharged.

Dr. Franklin also observed, that when the phial was charged, one side lost exactly as much as the other gained, in restoring the equilibrium. Hanging a small wire bent near the coating of an electrical phial, he observed, that whenever he brought his finger near the wire, the thread was attracted by the coating, for as the fire was taken from the inside, by touching the wire, the outside strove to get its quantity by the thread. He likewise proved, that the coating on one side of a phial received just as much electricity as was carried from the discharge of the other, in the following manner: he laid it on rubber, and this, charging a pallal to the conductor, he found it could not be charged, even though his hand was held constantly on it, because, though the electric fire might leave the outside of the phial, there was none collected by the rubber to be conveyed into the inside. He then took it off his hand from the phial, and forming a communication by a wire from the outside coating to the unelectrified rubber, he found that it was charged with ease. In this case, it was plain, that the very same fire which left the outside coating, was conveyed by the way of the rubber, the globe, and the conductor, and the wire of the phial, into the inside. This new theory of charging the *Leyden* phial led Dr. Franklin to observe a greater variety of facts relating both to charging and discharging it, than other philosophers had attended to. This matter, that whatever the phial takes in at one surface is lost at the other, led Dr. Franklin to think of charging several phials together with the same trouble, by connecting the outside of one with the inside of another; whereby the fluid that was driven out of the first would be received by the second, &c. By this means he found, that a great number of bottles might be charged with the same labour as one only; and that they might be charged equally high, were it not that every bottle receives the new fire, and loses its old with some reluctance, so that one gives some small reluctance to the charging. On this principle is constructed an *electrical* BATTERY.

When Dr. Franklin first began his experiments upon the *Leyden* phial, he imagined that the electric fire was all crowded into the substance of the non-electric, in contact with the glass; but he afterwards found, that its power of giving a shock lay in the glass itself, and not in the coating, by the following ingenious analysis of the bottle. In order to find where the strength of the charged bottle lay, he placed it upon glass; then first took out the cork and the wire, and finding the virtue was not in them, he touched the outside coating with one hand, and put the finger of the other into the mouth of the bottle; when the shock was felt quite as strong as if the cork and wire had been in it. He then charged the phial again, and pouring out the water into an empty bottle, imagined, expected, that if the force resided in the water, it would give the shock, but he found it gave none. He then judged that the electric fire must either have been lost in decanting, or must remain in the bottles; and the latter he found to be true; for, filling the charged bottle with fresh water, he found the shock, and was satisfied that the power of giving it resided in the glass itself. The same experiments was made with panes of glass, laying the coating on bothly, and changing it, as the water had been before changed in the bottle, and the result was precisely the same. He proved in other ways that the electric fire resided in the glass. Franklin's Letters and Observations, &c. Priestley's Hist. of Electricity, vol. i. p. 101, &c.

From the above account of Dr. Franklin's method of analyzing the *Leyden* phial, the manner of charging and discharging it, and the reason of the proceis, are eafily underflood. Thus, if a coated phial be placed near the prime conductor, (*Hift. Electricity, fig.* 4.) fo that the knob of its wire may be in contact with it; and the winch of the machine (*fig.* 5.) be turned, the index of the ELECTROMETER, E, fixed to the conductor, will gradually rife as far as 90° nearly, and then reft; which fhews that the phial has received its full charge; then if the difcharger (*fig.* 3.) be held by its glafs handle, and

one of its knobs be applied to the outside coating of the phial, and the other be brought near the knob of the wire, or near the prime conductor that communicates with it, a report will be heard, and luminous sparks will be discovered between the discharger and the conducting substances communicating with the sides of the phial; and by this operation the phial will be discharged. If, instead of using the discharger, a person touches the outside of the phial with one hand, and brings the other hand near the wire of the phial, the same spark and report will be observed, and a shock will be felt, that affects the wrists and elbows; and when the shock is strong, the breast likewise; and a shock may be given to any single part of the body, if that part alone be brought into the circuit. If a number of persons join hands, and the first of them touches the outside of the phial, and the last touches the wire communicating with the inside, they will all feel the shock at the same time. If the coated phial be held by the wire, and the outside coating be presented to the prime conductor, it will be charged as readily, only with this difference, that in this case the outside will be positive, and the inside negative: and if the prime conductor, by being connected with the rubber of the machine, be electrified negatively, the phial would be charged in the same manner; but the side that touches the conductor would be electrified negatively, and the opposite side would be electrified positively. But if the phial be INSULATED, and the same process repeated, the index of the electrometer will soon rise to 90°, yet the phial will remain uncharged; because the outside, having no communication with the earth, &c. cannot part with its own electricity, and, therefore, the inside can acquire no additional quantity; but when a chain, or any other conductor, connects the outside of the phial with the table, the phial may be charged as before. Moreover, if a phial be insulated, and one side of it, instead of being connected with the earth, be connected with the insulated rubber, whilst the other side communicates with the prime conductor, the phial will be expeditiously charged; because, whilst the rubber exhausts one side, the other side is supplied by the prime conductor; and in this way the phial is charged with its own electricity; or the natural electric matter of one of its sides is thus thrown on its other side. This last experiment may be diversified, by insulating the phial, and placing it with its wire at the distance of about half an inch from the prime conductor, and holding the knob of another wire at the same distance from its outside coating; then turning the winch of the machine, and a spark will be observed to proceed from the prime conductor to the wire of the phial, and another spark will pass at the same time from the outside coating to the knob of the wire, presented towards it; and thus it is seen, that as a quantity of the electric matter is entering the inside of the phial, an equal quantity of it is leaving the outside. If the wire presented to the outside of the phial be pointed, it will appear illuminated with a STAR; but if the pointed wire be connected with the coating of the phial, it will appear illuminated with a BRUSH of rays. See CHARGE, ELECTRICAL *Jhock*, and *Experiments*, &c. in ELECTRICITY.

Mr. Cavallo has described the construction of a phial, which, when charged by an electrical kite, in examining the state of the clouds, or in any other way, may be put into the pocket, and which will retain its charge for a considerable time. Besides the coating on the inside and outside, which this phial has like others of the same kind, a glass tube open at both ends is cemented into its neck, and passes within the phial, having a small wire fastened to its lower extremity, which touches the inside non-electric coating. The wire, with the knob of this phial, is cemented into another glass tube, which is nearly twice as long, and smaller than the tube cemented into the neck of the phial. The wire is cemented in such a manner, that only its knob projects out of one end, and a small length of it out of the other end of the tube. If this piece, with the wire, be held by the middle of the glass tube, it may be put in or out of the tube, which is in the neck of the phial, so as to touch the small wire at the lower extremity of it; and this may be done without discharging the phial, if it be charged. A phial of this kind has been kept in a charged state for six weeks. Cavallo's Elect. p. 340.

We shall close this article with an account of the method by which Mr. Cavallo repairs coated phials, that have been cracked or perforated, either by a spontaneous discharge, or other accident. He removes the outside coating from the fractured part, and then makes it moderately hot, by holding it to the flame of a candle; and whilst it remains hot, he applies burning sealing-wax to the part, so as to cover the fracture entirely; taking care that the thickness of this wax coating may be greater than that of the glass. Lastly, he covers all the sealing-wax, and also part of the surface of the glass beyond it, with a composition made with four parts of beef-wax, one of resin, one of turpentine, and a very little oil of olives. This he spreads upon a piece of oiled silk, which he applies in the manner of a plaster. In this way several phials have been so effectually repaired, that, after being frequently charged, they were at last broken by a spontaneous discharge, but in a different part of the glass. Phil. Trans. vol. lxxiii. part 2. p. 1011.

LEYGAGE, is used for wager of law.

LEYSERA, in *Botany*, a genus of the *frigenesia polygamia superflua* class, the receptacle of which is naked, the down chaffy, but plumose at the disc, and the calyx composed of leaves, dry at the margin, and rounding when touched.

LIBADION, in *Botany*, a name by which Pliny, and some other authors, have called the centaurium, or centory.

LIBANIUM, in *Botany*, a name given by Apuleius, and some other authors, to the common borago, or borrage.

LIBANOMANTIA, *Acromantia*, in *Antiquity*, a species of divination performed with frankincense; which, if it presently caught fire, and sent forth a grateful odour, was esteemed a happy omen, and *vice versâ*.

LIBATION, LIBATIO, a ceremony in the heathen sacrifices, wherein the priest spilt some wine, milk, or other liquor, in honour of the deity to whom the sacrifice was offered; after having first tasted it himself.

Alexander is said to have sacrificed a bull to Neptune; and, for an offering to the sea-gods, to have thrown the golden vessels used for the *libation* into the sea.

Libations were also in use under the law of Moses, being enjoined by God in Exodus xxix. and Numbers xv.

LIBAVIUS, *liquor of*. See LIQUOR.

LIBEL, *Famosus* LIBELLUS, a writing or report, unlawfully published abroad, containing injurious reproaches, or accusations, against the honour and reputation of any person, particularly of a superior, or governor.

Platina is of opinion, that a writing, how injurious soever it is, cannot be called a *libel*, if the author's name be to it. Libellers, among the ancient Romans, were punished with death, but in after-times they were only whipped. Augustus ranked *famosi libelli*, defamatory *libels*, among the crimes *laesæ majestatis*, of high treason, and under the emperor Valentinian it was made capital, not only to write, but to publish or even omit destroying them. F. Baldwin has published a comment on the imperial laws against *libels*. Scandalous pictures are reckoned amongst *libels*.

A *libel*, the lawyers say, may be either *in scriptis*, or *sine scriptis*: *in scriptis*, when a writing is composed, or published, to another's disgrace; which may be done either *verbis aut cantelenis*; as, where this is maliciously repeated, or sung, in the presence of others: or else *traditione*, when the *libel*, or any copy of it, is delivered out, to scandalize the party.

A *libel sine scriptis* may be twofold. 1. *Picturis*, as to paint the party in a shameful or ignominious manner: or, 2. *Signis*, as to fix a gallows, or other ignominious sign, at the door of the party, or elsewhere.

With regard to *libels* in general, there are two remedies; one by indictment and another by action. The former for the public offence; for every *libel* has a tendency to break the peace, or to provoke others to break it; which offence is the same, whether the matter contained be true or false: and, therefore, the defendant, on an indictment for publishing a *libel*, is not allowed to allege the truth of it by way of justification. In such prosecutions, the only facts to be considered are, first, the making or publishing of the book or writing; and secondly, whether the matter be criminal. The punishment of libellers, for making, repeating, printing, or publishing *the libel*, is fine, and such corporal punishment, as the court in their discretion shall inflict, according to the offence, and quality of the offender. But as the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may as for words spoken justify the truth of the facts, and shew what the plaintiff has received no injury at all. Blackst. Com. vol. iii. p. 126. and vol. iv. p. 150.

LIBEL, of *libelli, a little book*, also signifies the original declaration of any action in the civil law.

LIBEL, in *the Laws of Scotland*, is used for a criminal accusation or INDICTMENT.

LIBELLA, in *Natural History*. See DRAGON *Fly*.

LIBELLA, among the Romans, was the tenth part of the DENARIUS.

LIBELLATICI, an ancient kind of apostates from Christianity, under the persecution of Decius; who, to prevent their being obliged to renounce the faith, and sacrifice to idols in public, made application to the magistrates, and abjured their faith in private; obtaining certificates

of

of them, either by intreaty, or by money; by which they were attested to have complied with the orders of the emperor; and were thereby sheltered from any farther molestation on account of their religion.

These certificates were called *libelli*; whence the people who obtained them came to be denominated *Libellatici*. Others, particularly the centuriators of Magdebourg, are of opinion, that the *Libellatici* were only such as furnished the magistrates with money, to screen them from perfecution, and from being obliged to renounce Christianity.

M. Tillemont retains something of each opinion; he thinks, the *Libellatici*, applying themselves to the magistrates, bought off the sacrificing and abjuration; and obtained letters, by which they were declared to have renounced Christ, and sacrificed to idols; though, in effect, they had done neither.

LIBELLULA, in *Zoology*, the name of a genus of the *neuropteru* class of insects: the mouth of which is furnished with jaws, the antennæ shorter than the thorax, the wings extended, and the tail terminated by a kind of forceps.

The species of this genus are very numerous, by Linnæus reckoned twenty-one, some carrying their wings erect when they sit, and others horizontally.

LIBER, in *Botany*, the bark or rind, principally of trees. This is to be conceived as consisting of a number of cylindric and concentric surfaces, whose texture is reticular, and in some trees plainly extrusible every way, by reason that the fibres are soft and flexible. While in this condition they are either hollow regular canals, or, if not so, they have interstitial spaces, which serve the office of canals. The nutritious juice, which they are continually receiving, remains in part in them, and makes them grow in length and thickness, and strengthens and brings them closer together; and by this means the texture, which was before reticular, becomes an assemblage of straight fibres, ranged vertically, and parallel to each other; that is, as they are thus altered behind one another, they, by degrees, become a new substance more woody, and called LIGNUM. See BARK.

LIBERA, in *Mythology*, the name of a goddess, which Cicero, in his book Of the Gods, represents as the daughter of Jupiter and Ceres. Ovid in his Fasti says that the name was given by Bacchus to Ariadne.

Libera is exhibited on Medals, as a kind of female Bacchus, crowned with vine-leaves.

LIBERAL *arts*, are such as depend more on the labour of the mind than on that of the hand; or, that consist more in speculation than operation; and have a greater regard to amusement and curiosity than to necessity.

The word comes from the Latin *liberalis*; which, among the Romans, signified a person who was not a slave; and whose will, of consequence, was not checked by the command of any master.

Such are grammar, rhetoric, painting, sculpture, architecture, music, &c. The *liberal arts* used formerly to be summed up in the following Latin verse:

Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra.

And the *mechanical arts*, which, however, are innumerable, under this:

Rus, Nemus, Arma, Faber, Vulnera, Lana, Rates.

See ARTS.

LIBERALIA, feasts celebrated by the ancient Romans, in honour of Liber, or Bacchus, the same with those which the Greeks called DIONYSIA, and *Dionysian*.

They took their name from *liber*, i. e. *free*, a title conferred on Bacchus, in memory of the liberty or freedom, which he granted to the people of Bœotia; or, perhaps, because wine, whereof he was the reputed deity, delivers men from care, and sets their mind at ease and freedom. Varro derives the name of this feast from *liber*, considered as a noun adjective, and signifying *free*: because the priests were free from their function, and eased of all care, during the time of the *Liberalia*: as the old women officiated in the ceremonies and sacrifices of these feasts.

LIBERANDIS, *terris*. See TERRIS.

LIBERATE, in *Law*, a writ that lies for the payment of a yearly pension, or sum of money, granted under the great seal, and directed to the treasurer, chamberlains, and barons of the exchequer, &c. for that purpose.

In another sense it is a writ to the sheriff of a county, for the delivery of possession of lands, and goods extended, or taken upon the forfeiture of a recognizance.

Liberate is also used for a writ issuing out of the chancery, directed to a gaoler for delivery of a prisoner, who hath put in bail for his appearance.

LIBERI *tauri libertas*. See TAURI.

LIBERIA, a feast held among the Romans, on the day whereon their children laid aside their juvenile habits, and assumed the robe called *toga liberia*.

The *liberia* were kept on the sixteenth of the kalends of April; that is, on the seventeenth of March.

LIBERTAS *ecclesiastica*, *church liberty*; a frequent phrase in old writers, who treat of ecclesiastical immunities. The right of investiture, extorted from our kings by the papal power, was at first the only thing challenged by the clergy, as their *libertas ecclesiastica*, but by degrees under the title of *church liberty*, they contended for a freedom of their persons and possessions, from all secular power and jurisdiction; as appears by the canons and decrees of the councils held by Boniface, archbishop of Canterbury, at Merton, ann. 1258, and at London, ann. 1260, &c.

LIBERTATE *probanda*, in *Law*, an ancient writ that lay for such as being demanded for villains, offered to prove themselves free; directed to the sheriff, that he should take security of them for their proving of their freedom before the justices of assize, and that in the mean time they should be unmolested.

LIBERTATIBUS *allocandis*, in *Law*, a writ lying for a citizen or burgess, impleaded contrary to his liberty, to have his privilege allowed.

If any do claim a special liberty to be impleaded within a city or borough, and not elsewhere, there may be a special writ *de libertatibus allocandis*, to permit the burgesses to use their liberties, &c. These writs are of several forms, and may be sued by a corporation, or by any single person, as the case shall happen.

LIBERTATIS *Angliæ custodes*. See CUSTODES.

LIBERTUS, or LIBERTINUS, among the Romans, a *freedman*, or a person set free from a legal servitude.

These still retained some mark of their ancient state: he who made a slave free having a right of patronage over the *libertus*; so that if the latter failed of shewing due respect to his patron, he was restored to his servitude; and if the *libertus* died without children, his patron was his heir. See SLAVE.

In the beginning of the republic, *libertinus* denoted the son of a *libertus* or freed-man; but afterwards, before the time of Cicero, and under the emperors, the terms *libertus* and *libertinus*, as Suetonius has remarked, were used as synonymous.

LIBERTINES, LIBERTINI, in *Ecclesiastical History*, a religious sect, which arose in the year 1525, whose principal tenets were, that the Deity was the sole operating cause in the mind of man, and the immediate author of all human actions; that, consequently, the distinctions of good and evil, which had been established with regard to those actions, were false and groundless, and that men, could not, properly speaking, commit sin; that religion consisted in the union of the spirit or rational soul with the supreme being; that all those who had attained this happy union, by sublime contemplation and elevation of mind, were then allowed to indulge, without exception or restraint, their appetites or passions; that all their actions and pursuits were then perfectly innocent; and that, after the death of the body, they were to be united to the Deity.

They likewise said that Jesus Christ was nothing but a mere *je ne sçai quoi*, composed of the spirit of God, and of the opinion of men.

These maxims occasioned their being called *Libertines*; and the word has been used in an ill sense ever since.

The *Libertini* spread principally in Holland and Brabant. Their leaders were one Quintin, a Picard, Pockefius, Ruffus, and another called Chopin, who joined with Quintin, and became his disciple.

This sect obtained a certain footing in France through the favour and protection of Margaret, queen of Navarre, and sister to Francis I. and found patrons in several of the reformed churches. This sect was probably a remnant of the more ancient BEGHARDS or BRETHREN *of the Free Spirit*.

LIBERTINES *of Geneva*, were a cabal of rakes rather than of fanatics: for they made no pretences to any religious system, but pleaded only for the liberty of leading voluptuous and immoral lives. This cabal was composed of a certain number of licentious citizens, who could not bear the severe discipline of Calvin, who punished with rigour not only dissolute manners, but also whatever bore the aspect of irreligion and impiety. In this turbulent cabal there were several persons who were not only notorious for their dissolute and scandalous manner of living, but also for their atheistical impiety, and contempt of all religion. To this odious class belonged one Gruet, who denied the divinity of the Christian religion, the immortality of the soul, the difference between moral good and evil, and rejected with disdain the doctrines that are held most sacred among Christians; for which impieties he was at last brought before the civil tribunal, in the year 1550, and condemned to death. The Genevan spirit of reformation, improperly directed by the violence

lence and zeal of Calvin, did at this time operate to a degree, which has marked the character of this great reformer with reproach. For in 1544, Sebastian Castalio, master of the public school at Geneva, who was a man of probity, and distinguished by his learning and taste, was, nevertheless, deposed from his office and banished the city, because he disapproved some of the measures that were pursued and some of the opinions entertained by Calvin and his colleagues, and particularly that of absolute and unconditional predestination. Jerome Bolsec also, a man of genius and learning, who became a convert to the protestant religion and fled to Geneva for protection, was cast into prison, and, soon after, sent into banishment, because, in 1551, he imprudently and indecently declaimed in full congregation and at the close of public worship against the doctrine of absolute decrees. Mosheim.

LIBERTY, LIBERTAS, is usually understood of that state wherein a man acts freely; or that power by which he determines himself voluntarily either to good or evil, to this thing or that.

In this sense *liberty* amounts to the same with FREEDOM, and stands opposite to NECESSITY.

Liberty may be defined an active indifference of the will, to will, or not to will, any thing.

Most of the Schoolmen confound *liberty* and the will together, and make one definition serve for both. Whereas Mr. Locke observes, that *liberty* does not belong to the will, but to the man or agent; and therefore, that the question, in the usual manner of putting it, whether man's will be free or no, is absurd and unintelligible. *Liberty*, which is but a power, belongs only to agents, and cannot be an attribute or modification of the will, which is also but a power. They distinguish *liberty* into a great many kinds; as,

LIBERTY *of contrariety*, *contrariatis*, which is a freedom of doing two things, not only different, but contrary to each other.

LIBERTY *of contradiction*, a power either of doing a thing, or letting it alone. See FREEDOM.

LIBERTY, *next*, *proxima*, is a full absolute freedom of doing any thing.

LIBERTY, *remote*, is a *liberty* that comprehends a natural power, though embarrassed with obstacles, which it is in our power to remove, and to attain to a next *liberty*.

LIBERTY *of conscience*, a right or power of making profession of any religion, or of serving God in any manner that a man sees fit.

This seems to be a natural right; it is vigorously opposed by the generality of the Romanists, and even by many of the Reformed, though it seems as if the reformation could scarce subsist without it. See TOLERATION and PERSECUTION.

The nature of *liberty* may be better understood by dividing it, with an excellent writer, into *physical*, *moral*, *religious* and *civil*.

LIBERTY, *physical*, is that principle of spontaneity or self-determination, which constitutes us agents; or which gives us a command over our actions, rendering them properly our's and not effects of the operation of any foreign cause. Without this *liberty*, or being under a necessity of always following some will different from his own, man would be a machine acted upon by mechanical springs, having no principle of motion in himself or command over events; and, therefore, incapable of all merit and demerit.

Whether man is endued with this kind of *liberty* or self-determining power has been a subject of much controversy: it was agitated at the beginning of this century between Leibnitz, Collins, &c. on one side, and Clarke, Jackson, &c. on the other; and has been lately revived by Dr. Priestley.

Cicero defines *liberty*, the power of living after a man's own will, without any cause or impediment to oblige him to do the thing rather than another.

F. Malebranche gives us a still more philosophical definition: the will he defines to be that impression, or natural motion, which inclines towards good in the general; and by *liberty*, he understands, that power which the mind has of determining this general impression towards such objects as please us; and so of directing our general inclinations to some particular things.

Whence it is easy to perceive, that though all natural inclinations be voluntary, yet they are not all free; or, we mean, with *liberty* of indifference, which includes a power of willing, or not willing; or of willing quite the contrary to that which our natural inclinations lead us to. For, though it is voluntarily and freely that we love good in general, it is absurd to suppose we should love any thing without the will, or that the will can ever be constrained; yet we do not love it freely (in the sense just laid down) because it is not in the power of the will not to desire to be happy.

It must be observed, however, that the mind, considered as determined towards good in general, cannot divert its motion to any particular good, unless the same mind, considered as capable of ideas, have some knowledge of that particular good: that is, in plainer terms, the will is a blind power, that cannot direct itself to any thing but what the understanding represents to it; so that the power which the will has to determine its impression towards general good, or its natural inclinations, variously, consists in the power it has to command the understanding to represent some particular good.

Thus, a person, for instance, represents some dignity to himself as a good to be wished for, immediately the will desires this good; that is, the impression which the mind continually receives towards good in general, determines it to this dignity. But as that dignity is not the universal good, nor is conceived clearly and distinctly as such by the mind (for the mind cannot conceive a thing clearly which is not), the impression we have towards good in general, is not entirely exhausted by that particular good; the mind has an inclination to go further; it does not love that dignity necessarily or invincibly, and in this respect is free.

Now its *liberty* consists in this, that, not being fully convinced that this good contains in it all the good it is capable of enjoying, it may suspend its judgment and its desire.

The case is nearly the same with regard to the knowledge of truth: we love this, as we do the enjoyment of good, by a natural impression; which impression is not invincible in the latter, excepting evidence be full, and our knowledge of the object complete. We have the same *liberty* in our false judgments, that we have in our irregular appetites. See JUDGMENT, and WILL.

Mr. Locke defines *liberty* to be the power which a man has to do or forbear doing any particular action, according as its doing or forbearance has the actual preference in the mind, which is the same thing as to say, according as he himself wills it: and he observes, that so far as a man has power to think or not to think, to move or not to move, according to the preference or direction of his own mind, so far is a man free. This will be acknowledged, it always determined by some, and for the most part, by the most pressing uneasiness or desire of happiness. The *liberty* for which he contends, and for the existence of which he appeals to experience, is a *liberty* of suspending our determinations. The mind, he says, having in most cases, as is evident in experience, a power to suspend the execution and satisfaction of any of its desires, and so all one after another, is at *liberty* to consider the objects of them, examine them on all sides, and weigh them with others. In this lies the *liberty* a man has. He has a power to suspend the prosecution of this or that desire, as every one daily may experience in himself. This seems to be the source of all *liberty*. In this seems to consist, as he thinks, that which is improperly called free-will. And he adds further, that perfect indifference in the mind, not determinable by its last judgment of the good or evil, that is thought to attend its choice, would be so far from being an advantage and excellency of an intellectual nature, that it would be as great an imperfection as the want of indifference to act or not to act, till determined by the will, would be an imperfection on the other side. Eff. vol. 1. book 2. chap. 21. From these concessions the advocates for necessity have pleaded the authority of Mr. Locke, though he does not seem to have been apprized of the consequences of his principles. Mr. Hobbes, who seems to have been the first who understood and maintained the proper doctrine of philosophical necessity, defines *liberty* to be the absence of all impediments to action, that are not contained in the nature and intrinsic quality of the agent. And Mr. Collins, the principal writer on the side of necessity, defines *liberty* to be a power in man, to do as he wills, or pleases; though he denies, that we are at *liberty* to will, or not to will; or to will one or the other of two or more objects, between which, all things considered, we perceive a difference; or that we are free in our choice among things indifferent or alike.

Dr. Clarke has remarked, that in the above definition, there is an ambiguity in the words, "wills or pleases," because they may either denote the last perception or judgment of the understanding, which is entirely passive; or the first exertion of the self-moving power, which is essentially active. "Now, though the self-moving power is an adequate cause of action, yet understanding, or judgment, or assent, or apprehension, or liking, or whatever name it is called by, can no more possibly be the efficient cause of action, than rest can be the cause of motion. Nothing can possibly be the cause of an effect more considerable than itself. Nothing that is passive can possibly be the cause of any thing

that

that is active: an occasion indeed, it may be; and action may be consequent upon perception or judgment; it may easily be supposed to be always consequent upon it, and yet at the same time there may be no manner of physical or necessary connexion between them. Besides, the word "do" in this definition of Mr. Collins, has no significa-tion. For his meaning is not, that the man "acts or "does" any thing; but the *liberty* or power in man to do as he wills or pleases, is with him exactly and only the same as the *liberty* or power in a balance would be to move as it wills or pleases; supposing the balance en-dued with such a sensation or intelligence, as enabled it to perceive which way the weights turned it, and to ap-prove the motion, so as to fancy that it moved itself, when indeed it was only moved by the weights. Mr. Collins makes the difference between a man and a clock, to consist only in sensation and intelligence, not in any power of acting: whereas the whole essence of *liberty* consists in the power of acting: so that action and *liberty* are identical terms.

The principal arguments in favour of *liberty*, as it is po-pularly understood and as it is defined in the beginning of this article, are the following: this principle is necessary to constitute man an AGENT; for, as far as it is true of a being that he acts, so far he must himself be the cause of the action, and, therefore, not necessarily determined to act: but if he has no absolute power over his own actions, i. e. if he be not a free agent, the actions, which he performs, cannot properly be said to be his own, but must be ascribed to some other power, by which he is led on to perform them; as a good clock or watch performs the motions assigned to it by the artist. This argument is excellently illustrated by Dr. Clarke: man, says he, either has within himself a principle of action properly speaking, i. e. a self-moving faculty, a principle or power of beginning motion; or he has not. If he has within himself such a principle, then he is a free, and not a ne-cessary agent: for every necessary agent is moved necessa-rily by something else; and then that which moves it, not the thing itself which is moved, is the true and only cause of the action. That any other thing operating upon an agent, should efficiently and necessarily produce self-motion in that agent, is a direct contradiction in terms. If man has not within himself a principle or power of self-mo-tion, then every motion and action of man is chiefly and properly produced by the efficiency of some extrinsic cause; which cause must be either what we usually call the motive or reason upon which a man acts; or else it must be some insensible subtile matter, or some other being or substance making an impression upon him. If, the reasons or motives upon which a man acts be the im-mediate and efficient cause of the action, then either abstract notions, such as all reasons and motives are, have a real subsistence, that is, are themselves substances; or else that which has itself no real subsistence can put a body into motion; either of which is manifestly ab-surd. If insensible subtile matter, or any other being or substance, continually making impression upon a man, be the immediate and efficient cause of his acting; then the motion of that subtile matter or substance must be caused by some other substance, and the motion of that by some other, till at last we arrive at a free agent; and then *liberty* is a possible thing, and man possibly may have *liberty*: and if he may possibly have it, then experience will prove that he probably, nay, that he certainly has it. If we never arrive at any free cause, then there is either *in infinitum* a progression of motions without any mover, of effects without any cause, of things acted without any agent; which is a manifest contradiction: or else motion exists necessarily of itself. If motion exists necessarily of it-self, it must be either with a determination every way, or one certain way; if with a determination every way, this is no motion at all; if with a determination one cer-tain way, then that determination is either necessary, and consequently all other determinations impossible, which is contrary to experience; or else there must be a parti-cular reason of that determination, and so backwards *in infinitum*, which comes to the forementioned absurdity, of effects existing without any cause.

Farther, *liberty* is the dictate of our own consciousness: we have, really, the same constant and necessary conscious-ness of *liberty* that we have that we think, choose, will, or even exist; and whatever men may say to the contrary, it is impossible for them, in earnest, to think they have no active self-moving powers, and are not the causes of their own volitions; or not to ascribe to themselves what they must be conscious they think and do. Mr. Hume, though he denies the reality of *liberty*, grants that we have a feeling of it; that the divine plan required that we should be so made, as to seem to ourselves free; that the whole constitution of things is as if we were free; and that being under a necessity of approving and disapproving actions and characters, we are so far under a necessity of believing ourselves and others free. After these con-cessions, it can hardly be imagined that the constitution of nature should be altogether imposition and deceit.

Besides, if man be not, in the strictest sense of the word, a free agent, he can be no moral agent. It is hard to say, what virtue and vice, commendation and blame, mean, if they do not suppose agency, voluntary motion, free choice and an absolute dominion over our resolutions. Can we approve or reproach ourselves for what we were no more the causes of than of our own beings, and what it was no more possible for us to prevent than the returns of the seasons, or the revolutions of the planets? On the system of necessity, conscience is an inexplicable principle: its censures or applause are equally futile and groundless: the approbation of mankind is an insult with regard to those on whom it is bestowed, because they can have no merit; and the reproach of men unjust and cruel, because there can be no demerit and ground of blame. Whatever difficulties, therefore, may attend the nature of that influence which we ascribe to motives, they cannot be the efficient necessitating cause of human actions: since, on this supposition, there could be but one agent in the universe; who must equally be the author of all the good and evil in the world, and on whom must ultimately be charged the sin and misery, as well as the virtue and happiness of his creatures.

Moreover, it has been urged by the advocates of *liberty*, that if men's determinations and actions flow necessarily from the previous state of their minds and the motives or influences resulting from a nature or condition imposed upon them without their own consent or choice, the idea of responsibility or accountableness must vanish, and there can be no propriety or use of rewards or punish-ments. God cannot reward without virtue, and there can be no virtue without a self-determining power: he cannot punish without guilt, and there can be no guilt when men do what they cannot avoid doing, and when their actions arise from circumstances in which their Creator placed them.

It is also equally unjust and useless to threaten punishment or inflict it on men to prevent crimes, when they are necessarily determined in all their actions. And if men are necessary agents, though we cannot well admit this verbal contradiction, it can be of no use to reason with them, to admonish or interest them; and God must be insincere in his addresses and invitations, and cruel in his requirements and commands. But such is the whole tenour of revelation, and, therefore, the conclusion is necessary, that man is a free agent, capable of good or evil, and of determining his pursuit of either, from the sole power of his own judgment or will. See on this subject Collins's Enquiry concerning Human Liberty, first printed in 1717. Clarke's Remarks, 1717, and Collec-tion of Papers which passed between Mr. Leibnitz and Dr. Clarke, in 1715 and 1716. Jackson's Vindication and Defence of Human Liberty, 1730. Price's Review of the principal Questions, &c. in Morals, p. 315, &c. edit. 1758. Priestley's Doctrine of Philosophical Ne-cessity, 1777. For the objections against *liberty* and the arguments in support of necessity, see NECESSITY.

LIBERTY, *moral*, is the power of following, in all circum-stances, our sense of right and wrong; or of acting in conformity to our reflecting and moral principles, without being controlled by any contrary principles.

LIBERTY, *religious*, is the same with LIBERTY *of con-science*, and signifies the power of exercising, without molestation, that mode of religion which we think best; or of making the decisions of our own consciences, re-specting religious truths, the rule of our conduct, and not any of the decisions of others.

LIBERTY, *civil*, is the power of a civil society or state, to govern itself by its own discretion; or by laws of its own making, without being subject to any foreign dis-cretion, or to the impositions of any extraneous will or power. Civil *liberty*, says Judge Blackstone, adopting the definition of the Institutes, consists in the power of doing whatever the laws permit; or it is natural *liberty*, or a power of acting as one thinks fit, without any re-straint or control, unless by the law of nature, so far restrained by human laws, and no farther, as is necessary and expedient for the general advantage of the public. Others have defined *civil liberty* in contradistinction from *political* LIBERTY to be that power over their own actions, which the members of the state reserve to themselves, and which their officers must not infringe. This ex-tends no farther than to a man's own conduct, and sig-nifies the right he has to be exempt from the control of the society or its agents, that is, the power he has of providing for his own advantage and happiness. It is a man's civil *liberty*, which is originally in its full force, and part of which he sacrifices when he enters into a state of society.

LIBERTY, *political*, sometimes used as synonymous with

tivil *liberty*, in a diſtinct ſenſe, conſiſts in the power, which the members of the ſtate reſerve to themſelves of arriving at the public offices, or at leaſt, of having votes in the nomination of thoſe who fill them: and this is that which a man may or may not require in the compenſation he receives for it. In countries where every member of the ſociety enjoys an equal power of arriving at the ſupreme offices, and conſequently of directing the ſtrength and the ſentiments of the whole community, there is a ſtate of the moſt perfect political *liberty*. On the other hand, in countries where a man is, by his birth or fortune, excluded from theſe offices, or from a power of voting for proper perſons to fill them; that man, whatever be the form of the government, or whatever civil *liberty* or power over his own actions he may have, has no power over thoſe of another; he has no ſhare in the government, and therefore has no political *liberty* at all. Nay, his own conduct, as far as the ſociety does interfere, is, in all caſes, directed by others.

LIBERTY, *perſonal*, conſiſts in the power of loco-motion, or of changing ſituation, or removing one's perſon to whatſoever place one's own inclination may direct, without impriſonment or reſtraint, unleſs by due courſe of law. See HABEAS *corpus*.

LIBERTY *of the tongue*, in the *Manege*, is a void ſpace left in the middle of a bit, to give place to the tongue of a horſe, made by the bit's arching in the middle, and riſing towards the roof of the mouth. The bit, according to the various forms of the *liberty*, acquires different names; hence we ſay a *ſmutzle-mouth*, a *Pignatelli*, i. e. with the *liberty* after Pignatelli's faſhion, and a *canon-mouth*, with the *liberty* like a pigeon's neck.

In forging the bit, care muſt be taken not to make the *liberty* too high, leſt it hurt, or at leaſt tickle the palate, and make the horſe carry low.

LIBERTY, in *Mythology*, was a goddeſs both among the Greeks and Romans. Among the former ſhe was invoked under the title Eleutheria; and by the latter ſhe was called *Libertas*, and held in ſingular veneration; temples, altars, and ſtatues, were erected in honour of this deity. A very magnificent temple was conſecrated to her on mount Aventin, by Tiberius Gracchus, before which was a ſpacious court, called *atrium libertatis*. The Romans alſo erected a new temple in honour of *Liberty*, when Julius Cæſar eſtabliſhed his empire over them, as if their *liberty* had been ſecured by an event which proved fatal to it. In a medal of Brutus, *Liberty* is exhibited under the figure of a woman, holding in one hand a cap, the ſymbol of *liberty*, and two poniards in the other, with the inſcription IDIBVS MARTIIS.

LIBETHRIDES, in *Mythology*, a ſurname given to certain nymphs which were ſuppoſed to inhabit near mount Libethra in Beotia; and the Libethreian fountain in Theſſaly led the poets to call the Muſes by this name. Virgil, Eclog. vii. v. 21.

LIBITINA, in the *Roman Mythology*, a goddeſs which preſided over funerals. This goddeſs was the ſame with the *Venus inferna* or *Epitymbia* of the Greeks. She had a temple at Rome, where was lodged a certain piece of money for every perſon who died, whoſe name was recorded in a regiſter called *Libitinæ ratio*. This practice was eſtabliſhed by Servius Tullius, in order to obtain an account of the number of annual deaths, in the city of Rome, and conſequently the rate of increaſe or decreaſe of its inhabitants.

LIBONOTUS, in *Phyſiology*, one of the twelve winds of the ancients. See WIND.

LIBRA, *balance*, one of the mechanical powers. See BALANCE.

LIBRA is one of the twelve ſigns of the zodiac; exactly oppoſite to Aries; ſo called, becauſe when the ſun is in this ſign, at the autumnal equinox, the days and nights are equal, as if weighed in a balance.

The ſtars in this conſtellation according to Ptolemy are ſeventeen, Tycho ten, Hevelius twenty, and Flamſtead fifty-one. Their names, &c. are as follow:

LIBRA alſo denotes the ancient Roman pound, borrowed from the Sicilians, who called it *litra*, λίτρα.

The *libra* was divided into twelve unciæ, or ounces, and the ounce into twenty-four ſcruples.

The diviſions of the *libra* were, the *uncia*, one twelfth; the *ſextans*, one ſixth; the *quadrans*, one fourth; the *triens*, one third; the *quincunx*, five ounces; the *ſemis*, ſix; the *ſeptunx*, ſeven; the *bes*, eight; the *dodrans*, nine; the *dextans*, ten; the *deunx*, eleven; laſtly, the *as* weighed twelve ounces, or one *libra*.

Learned writers are not agreed as to the true weight of the Roman pound. Villalpandus and Greaves, relying on the cenſus of Veſpaſian for its ſtandard weight, have from hence attempted to determine this intricate queſtion. This Roman cenſus contained ten pounds weight of wine: Villalpandus found by filling it with ſpring water, that it contained juſt ten modern Roman pounds, which are equal to 52560 Troy grains. About filled it to the ſame height, and, having weighed its contents twice, found a reſult very nearly agreeing with Greaves's meaſure, ſtated by Miller, in Phil. Tranſ. vol. li. p. 790. His greater weight was 63074 Paris grains, equal to 51695 Troy; his leſſer, 62780 Paris grains equal to 51482 Troy. The mean between both is 51591 Troy grains, which, divided by 10, give 5159 ſuch grains for the weight of the ancient Roman pound. Several objections have been made to this pound derived from the cenſus, which Mr. Roper, *ubi ſupra*, has collected into one view; from which he infers, that it is more probable, that this ſtandard ſhould give too great a Roman pound, than too ſmall a one. But as the reſult from hence muſt be uncertain, he has recourſe to the coins. Having weighed nine gold pieces in the Pembroke collection, containing 343 Roman ſcruples, he found their weight to amount to 608 Troy grains, which divided by 343, give 1771 for the ſcruple, whence the Roman pound ſhould weigh 507355 grains. From ſome other coins of the ſame kind, a ſcruple appears to be 174 grains.

grains. Instead of this scrupular standard, another was introduced by Sylla; and from the heaviest of four pieces of this standard, allowing thirty of them to have been coined out of the Roman pound, its weight is found to be 5040 grains. The standard of forty in the pound, mentioned by Pliny, succeeded this of Sylla, and continued to the establishment of the monarchy under Augustus: and from ten different coins of this standard, he deduces a mean AUREUS of 126 grains; and supposing the aureus of forty in the pound to weigh 126 Troy grains, the Roman pound must weigh 5040. In Pliny's time forty-five aurei were struck out of the pound; and the mean aureus from Nero to Titus, in whose reign Pliny died, was under 112 grains: and if the standard weight of the imperial aureus of forty-five in the pound did not exceed 112 grains, the Roman pound will weigh 5040 grains, as it is found from the consular aureus. Soon after the reign of Alexander Severus, in whose time the aureus came to be called solidus, the coinage became very irregular, till Constantine entirely modelled it anew, by coining seventy-two solidi of four scruples out of the pound of gold. From twenty-nine of these solidi in the interval from Constantine to Heraclius, it appears that the mean weight is 69 grains, which, multiplied by 72, gives but 4968 grains for the Roman pound. But if the standard weight of this coin amounted to 70 grains, the pound will weigh 5040, as before. If we take 5040 Troy grains for the weight of the Roman pound, the scruple will weigh 17½ grains: the consular aureus 126; the imperial aureus 112, and the solidus 70; and the consular denarius of 84 in the pound will weigh just 60 Troy grains. Phil. Trans. vol. lxi. part 2. p. 461, &c. See further on this subject the articles DENARIUS and MILIARENSIS.

The Roman *libra* was used in France for the proportions of their coin, till the time of Charlemagne, or perhaps till that of Philip I. in 1093, their sols being so proportioned, as that twenty of them were equal to the *libra*. By degrees, it became a term of account; and every thing of the value of twenty sols, was called a *livre*.

LIBRA *pensi*, in our *Law Books*, denotes a pound of money in weight.

It was usual, in former days, not only to tell the money, but to weigh it; because many cities, lords, and bishops, having their mints, coined money, and often very bad too; for which reason, though the pound consisted of twenty shillings, they always weighed it.

LIBRARII, among the ancients, were a sort of copyists, who transcribed in beautiful, or, at least, legible characters, what had been written by the notarii in notes and abbreviatures.

LIBRARY, an edifice or apartment destined for the placing of books; or the collection of books themselves lodged therein. See BOOK.

Some authors refer the origin of *libraries* to the Hebrews; and observe, that the care those took for the preservation of their sacred books, and the memory of what concerned the actions of their ancestors, became an example to other nations, particularly to the Egyptians. Osmanduas, king of Egypt, is said to have taken the hint first; who, according to Diodorus, had a *library* built in his palace, with this inscription over the door, ΨΥΧΗΣ ΙΑΤΡΕΙΟΝ. Nor were the Ptolemies, who reigned in the same country, less curious and magnificent in books.

The Scripture also speaks of a *library* of the kings of Persia, Ezra v. 17. vi. 1. which some imagine to have consisted of the historians of that nation, and of memoirs of the affairs of state; but, in effect, it appears rather to have been a depository of laws, charters, and ordinances, of the kings. The Hebrew text calls it the *house of treasures*, and afterwards the *house of the rolls*, where the treasures were laid up. We may, with more justice, call that a *library*, mentioned in the second of Esdras to have been built by Nehemiah, and in which were preserved the books of the prophets, and of David, and the letters of their kings.

The first who erected a *library* at Athens, was the tyrant Pisistratus; and yet Strabo refers the honour of it to Aristotle. That of Pisistratus was transported by Xerxes into Persia, and was afterwards brought back by Seleucus Nicanor to Athens. Long after, it was plundered by Sylla, and re-established by Hadrian. Plutarch says, that under Eumenes there was a *library* at Pergamus, containing two hundred thousand books. Tyrannion, a celebrated grammarian, contemporary with Pompey, had a *library* of three thousand volumes. That of Ptolemy Philadelphus, according to A. Gellius, contained seven hundred thousand, all in rolls, burnt by Cæsar's soldiers. See ALEXANDRIAN.

Constantine, and his successors, erected a magnificent one at Constantinople; which, in the eighth century, contained three hundred thousand volumes, all burnt by order of Leo Isaurus; and, among the rest, one wherein the Iliad and Odyssey were written in letters of gold, on the guts of a serpent.

The most celebrated *libraries* of ancient Rome, were the Ulpian, and the Palatine. They also boast much of the *libraries* of Paulus Æmilius, who conquered Perseus; of Lucilius Lucullus, of Asinius Pollio, Atticus, Julius Severus, Domitius, Serenus, Pamphilus Martyr, and the emperors Gordian and Trajan.

Anciently, every large church had its *library*; as appears by the writings of St. Jerom, Anastasius, and others. Pope Nicholas laid the first foundation of that of the VATICAN, in 1450. It was destroyed by the constable Bourbon, in the sacking of Rome, and restored by pope Sixtus V. and has been considerably enriched with the ruins of that of Heidelberg, plundered by count Tilly in 1622. One of the most complete *libraries* in Europe, was said to be that erected at Florence by Cosmo de Medicis; over the gate whereof is written, LAUDE ASSEQUI LABOREM; though it is now exceeded by that of the French king; begun by Francis I. augmented by cardinal Richelieu, and completed by M. Colbert.

The emperor's *library* at Vienna, according to Lambecius, consists of eighty thousand volumes, and fifteen thousand nine hundred and forty curious medals.

The Bodleian *library* at Oxford, built on the foundation of that of duke Humphry, exceeds that of any university in Europe, and even those of all the sovereigns of Europe, except the emperor's, and French king's, which are each of them older by a hundred years. It was first opened in 1602, and has since found a great number of benefactors; particularly Sir Robert Cotton, Sir H. Savil, archbishop Laud, Sir Kenelm Digby, Mr. Allen, Dr. Pococke, Mr. Selden, and others. The Vatican, the Mediccan, that of Bessarion at Venice, and those just mentioned, exceed the Bodleian in Greek manuscripts; which yet outdoes them all in Oriental manuscripts.

As to printed books, the Ambrosian at Milan, and that of Wolfenbuttle, are two of the most famous, and yet both inferior to the Bodleian.

LIBRARY, *king's*, at St. James's, was founded by Henry, eldest son of James I. and made up partly of books, and partly of manuscripts, with many other curiosities, for the advancement of learning. It has received many additions from the *libraries* of Isaac Casaubon, and others.

LIBRARY, *Cottonian*, originally consisted of nine hundred and fifty-eight volumes of original charters, grants, instruments, letters of sovereign princes, transactions between this and other kingdoms and states, genealogies, histories, registers of monasteries, remains of Saxon laws, the book of Genesis, thought to be the most ancient Greek copy extant, and said to have been writ by Origen in the second century, and the curious Alexandrian copy of manuscript, in Greek capitals. This *library* is kept in the British Museum, with the large and valuable *library* of Sir Hans Sloane, amounting to upwards of forty-two thousand volumes, &c. There are many public *libraries* belonging to the several colleges at Oxford and Cambridge, and the universities in North Britain. The principal public *libraries* in London, beside that of the Museum, are those of the college of heralds, of the college of physicians, of Doctors Commons, to which every bishop, at the time of his consecration, gives at least 50*l.* sometimes 50*l.* for the purchase of books, those of the Gray's Inn, Lincoln's Inn, Inner Temple, and Middle Temple; that of Lambeth, founded by archbishop Bancroft in 1610, for the use of succeeding archbishops of Canterbury, and increased by the benefactions of archbishops Abbot, Sheldon, and Tennison, and said to consist of, at least, fifteen thousand printed books, and six hundred and seventeen volumes in manuscript; that of Red-Cross street, founded by Dr. Daniel Williams, a presbyterian divine, and since enriched by many private benefactions; that of the *Royal* SOCIETY, called the Arundelian or Norfolk *library*, because the principal part of the collection formerly belonged to the family of Arundel, and was given to the society by Henry Howard, afterwards duke of Norfolk, in 1666, which *library* has been increased by the valuable collection of Francis Aston, esq. in 1715, and is continually increasing by the numerous benefactions of the works of its learned members, and others; that of St. Paul's, of *Sion* COLLEGE, the queen's *library*, erected by queen Caroline in 1737; and the surgeon's *library*, kept in their hall in the Old Bailey, &c.

Where a *library* is erected in any parish, it shall be preserved for the uses directed by the founder; and incumbents and ministers of parishes, &c. are to give security for it, and make catalogues of the books, &c. None of the books shall be alienable, without consent of the bishop, and then only when there is a duplicate of such books. If any book shall be taken away and detained, a

justice's

juſtice's warrant may be iſſued to ſearch for, and reſtore the ſame: alſo action of trover may be brought in the name of the proper ordinary, &c. And biſhops have power to make rules and orders concerning *libraries*, appoint perſons to view their condition, and enquire of the ſtate of them in their viſitations. Stat. 7 Anne, cap. 14.

LIBRATA *terræ*, a portion of ground, containing four oxgangs, and every oxgang thirteen acres.

With us, it is ſo much land as is yearly worth 20*s*. In Henry the third's time, he that had *quindecim librata terræ*, was to receive the order of knighthood.

Some ſay, that as money is divided into pounds, ſhillings, pence, and farthings, the ſame degrees are to be obſerved in the diviſion of lands; and, therefore, as *quadrans* ſignifies a farthing, ſo *quadrantata* is the fourth part of an acre; *obolata* an half; *denariata*, a whole acre; *ſolidata*, 12 acres; and *librata*, 20 times 12 acres; i. e. 240 acres.

This is the ſame with what in Scotland is called POUND-*land* of old extent.

LIBRATION, in *Aſtronomy*, an apparent irregularity in the motion of the moon, by which ſhe ſeems to *librate*, or waver about her own axis; ſometimes from the eaſt to the weſt; and ſometimes from the weſt to the eaſt. See MOON.

Hence it is, that ſome parts in the moon's weſtern limb, or margin, at one time, recede from the center of the diſc, and at another, move towards it; by which means, ſome of thoſe parts, which were before viſible, ſet and hide themſelves in the inviſible ſide of the moon, and afterwards become again conſpicuous.

This *libration* of the moon is owing to her equable rotation round her own axis, and her unequal motion in the perimeter of her orbit. For if the moon moved in a circle, whoſe center coincided with the center of the earth, and turned round its axis in the preciſe time of its period round the earth, the plane of the ſame lunar meridian would always paſs through the earth, and the ſame face of the moon would be conſtantly and exactly turned towards us. But ſince the real motion of the moon is in an ellipſis, in whoſe focus is the earth, and the motion of the moon about the earth is equable; or, which is the ſame thing, every meridian of the moon, by the rotation, deſcribes angles proportional to the times, the plane of no one meridian will conſtantly paſs through the earth.

LIBRATION *of the earth*, is a term applied by ſome aſtronomers to that motion, whereby the earth is ſo retained in its orbit, as that its axis continues conſtantly parallel to the axis of the world. See PARALLELISM.

This Copernicus calls the *motion of libration*; and may be illuſtrated thus: ſuppoſe a globe, with its axis parallel to that of the earth, painted on the flag of a maſt, moveable on its axis, and conſtantly driven by an eaſt wind, while it ſails round an iſland; it is evident, the painted globe will be ſo *librated*, as that its axis will be parallel to that of the world, in every ſituation of the ſhip.

LICE. See LOUSE.

LICE *of trees*. See APHIS.

LICENCE, *licentia*, in *Law*, a power or authority given to another to do ſome lawful act.

A *licence* is a perſonal power, and cannot be tranſferred to another, though a *licence* may be granted to a man and his aſſigns.

LICENCE *to alien in mortmain*. Alienations in mortmain to eccleſiaſtical perſons, &c. are reſtrained by ſeveral Statutes; but the king may grant *licences* to any perſon or bodies politic, &c. to alien or hold lands in MORTMAIN. 27 Ed. I. 7 & 8 W. III. cap. 37.

LICENCE is alſo uſed, in the *Civil Law*, for a permiſſion or leave granted by a ſuperior.

Juſtinian appointed four years to be ſpent in the ſtudy of the law; after which, thoſe who had diſcharged this obligation, were ſaid to have *licence* or permiſſion to retire from ſtudy.

LICENCE is alſo applied to the letters, or certificates, taken out in univerſities, whether in law, phyſic, or divinity.

Licence, in the Sorboune, denotes a period of two years, which the bachelors are obliged to paſs in aſſiſting at acts, and diſputing in them, to qualify themſelves for being admitted doctors. See DEGREE.

LICENCE, *letter of*. See LETTER.

LICENCE *to ſeiſe*, in *Law*, LICENTIA *ſurgendi*, is a liberty, or ſpace of time given by the court to a tenant, who is eſſoined *de malo lecti* in a real action, to riſe out of his bed, and go about his buſineſs.

LICENCE *for election of biſhops*. See CONGE *d'eſlire*.

LICENCE *of marriage*. Biſhops have power to grant *licences* for this purpoſe; and perſons marrying any perſon without publiſhing the banns of matrimony, or without *licence*, incur a forfeiture of 100*l*. &c. by 7 & 8 W. III. cap. 35. See MARRIAGE.

LICENCE, in *Painting*, are the liberties which the painter takes in diſpenſing with the rules of perſpective, and the other laws of his art.

LICENCE, *poetical*, is the liberty which poets claim of diſpenſing with the ordinary rules of grammar.

Anciently, poets had much greater *licences* than are now allowed. The Greeks, by having recourſe to the ſeveral dialects of their tongue, could lengthen out a word, if it were too ſhort, or retrench ſomething from it, if it were too long. The old poets did what they pleaſed with their language, and ſubjected it not only to all their caprices, but their caprices too:

Et data Romanis venia eſt indigna poetis.

But theſe became ridiculous in courſe of time; and the poets are now deſpoiled of moſt of their ancient privileges.

LICENSED *curate*. See CURATE.

LICENTIA *concordandi*, in *Law*, is that *licence* for which the *king's* SILVER is paid in paſſing a fine, mentioned in 12 Car. II. cap. 12.

LICENTIA *loquendi*. See EMPARLANCE.

LICENCIATE, or LICENTIATE, he who has obtained the degree of a *licence*.

Moſt of the officers of juriſdicture in Spain are known by no other name than that of *licenciates*. To paſs *licenciate* in the common law, civil law, or phyſic, they muſt have ſtudied ſeven years; in divinity, ten.

LICENTIATE, among us, is uſually underſtood of a phyſician, who has a *licence* to practiſe, granted him by the COLLEGE *of phyſicians*, or by the biſhop of the dioceſe.

A perſon practiſing phyſic without ſuch *licence*, in caſe his patient dies under his hands, is guilty of felony in the eye of the law.

LICETO, in *Ornithology*. See CENOTAQUE.

LICHANUS, in the *ancient Muſic*, the name of one of the founds of a tetrachord. It was next to the nete.

The word is Greek, λιχανος, and ſignifies *index*.

The reaſon of the appellation was, that the *lichanus* ſhewed whether, and how far the genus was *molle* or *intenſum*. For the more remote the *lichanus* was from the moſt acute ſound in the tetrachord, the more did the genus partake of the *molle*. And, on the contrary, the nearer the *lichanus* approached to this higheſt note, the genus was reckoned the more intenſe. Vide Wallis, Append. ad Ptolem. Harm. p. 160.

This is Dr. Wallis's account of the matter. And, indeed, the reaſon of the name *lichanus* is not at all myſterious, if we conſider that the ſound of this chord was different in every one of the genera, whereas the ſound of the partipate remained the ſame in three different genera, and could not therefore be an index or characteriſtic of thoſe genera, which were, the *chromaticum temperatum*, the *diatonicum molle*, and the *diatonicum intenſum*. See CHROMATIC and DIATONIC.

LICHANUS *hypaton*, λιχανος ὑπατων, in the Greek ſcale of muſic, was the penultimate note of the hypaton tetrachord, and anſwers to *D ſol re ut*. See Guido's ſcale. See DIAGRAM.

LICHANUS *meſon*, λιχανος μεσων, in the Greek muſic, was the penultimate note of the *meſon* tetrachord, and anſwers to Guido's *G ſol re ut*. See DIAGRAM.

LICHEN, in *Botany*. See LIVER-wort.

LICHEN, Λειχην, in *Medicine*, a cutaneous diſtemper, otherwiſe called IMPETIGO.

LICHENASTRUM, in *Botany*, the name of a genus of plants, called JUNGERMANNIA, in the Linnæan ſyſtem, ſo called from the *lichen* or *liver-wort*, the flowers of which thoſe of this genus ſomewhat reſemble. The characters of the *lichenaſtra* are theſe: the flower is naked, and of the antherocous kind, globoſe at its firſt appearance, but ſoon after burſting open into a ſtellate or cruciform four-leaved flower, of the reſemblance of one, much like that of the gallium; this ſheds a fine duſt, or true farina, and is ſuſtained on a pedicle ſingly, and coming out of a theca or cup, which in ſome is undivided, in others is divided into two or more ſegments, repreſents a true flower. All the moſſes which have this ſort of flower are to be ranked in this genus, however widely they differ from one another in their external general form.

The firſt order of the *lichenaſtra*, according to Dillenius, contains thoſe with ſhoots and branches of a determinate figure; and of theſe the firſt ſeries conſiſts of ſuch as have leaves all ſet one way. Dillen. Hiſt. Muſc. p. 486.

The ſecond ſeries of theſe *lichenaſtra* comprehends thoſe, which have their leaves ſet on each ſide the ſtalks, and reſemble in miniature the ſeveral kinds of the trichomanes and aſplenium: the firſt diviſion of theſe comprehends thoſe which have ſimple pinnæ, placed alternately againſt one another, and the middle rib naked.

The firſt ſubdiviſion comprehends thoſe which have whole pinnæ, or at the utmoſt ſuch as are only ſlightly crenated.

The

The second division of these *lichenastra* comprehends those which have pinnæ cut into two or three segments, or as it were prickly.

The third division of these *lichenastra* takes in those which are pinnated and resemble the trichomanes, but which have their middle rib hid, or covered by the auriculæ of the pinnæ, or else by secondary ones.

The first subdivision of these comprehends those which have the middle rib covered by the auriculæ of the pinnæ.

The second subdivision of these *lichenastra*, comprehends those which have the lower part of their middle rib covered with either one single foliage, or with a series of intermediate pinnæ.

The third series of these *lichenastra*, comprehends those which are imbricated, or have their pinnæ standing closer upon, and lying over one another, and standing less out from the surface of the stalks. The first division of these takes in those which have scales or pinnæ, as it were furnished with a secondary scale below.

The second division of these *lichenastra* contains those which have the ribs or nerves of the branches covered underneath by a sort of secondary squamæ.

The fourth series of these *lichenastra* takes in those which are every way surrounded with leaves.

The second order of these *lichenastra* comprehends those which have leaves variously and indeterminately divided, which creep upon the ground, and have no stalks except the pedicles.

The third order of the *lichenastra* comprehends a few species, of which the author was less perfectly informed than of the rest, not having seen their heads, or absolutely depending on the accounts of them.

LICHENOIDES, in *Botany*, the name of a genus of *algæ*, the characters of which are these: they are composed of parts of different figure and structure, not simple and uniform as the byssi; they have usually no stalk, but grow on the branches of trees, on stones, and other bodies, either in form of a mere crust, or of leaves variously divided, and raised. They have tubercles on the several parts of these, serving in the place of flowers or seeds, and growing closely upon the leaves without pedicles. Michell has described the flowers and seeds of these plants from microscopic observations, but these are too minute to form generical distinctions on. These plants have the name *lichenoides*, from their resemblance to the *lichen*, or liverwort, as they consist, like it, of leaves diffused every way. They have hence been called by some *lichenes*; but the difference between the two genera is very great, these having very imperfect flowers, the others the most perfect of all the moslea.

The *lichenoides* are a very numerous genus, and are therefore divided into several subordinate series, or orders.

Of the first order, are those which have no leaves, but are merely crustaceous. Dillen. Hist. Musc. p. 144.

The second order of the *lichenoides* comprehends those which have regular scutellæ appearing in manner of flowers; these are little hollowed cups, as it were, surrounded with a kind of rim.

This order comprehends the foliaceous *lichenoides*. Of these some are of a gelatinous substance, and have tubercles and scutellæ.

Of the gelatinous *lichenoides*, the following are the known species of the dry and more rigid kinds, which have regular scutellæ.

These have their scutellæ standing on pedicles, more or less long; the other kinds have them applied close to the surface of the leaves, and usually of one colour: the leaves of these are more or less broad, and generally grow out from stones, or the branches of trees.

These have all their leaves, more or less, free; but there are some species which have them closely adhering, in every part, to the stone or wood on which they grow.

The third series of the *lichenoides* takes in those which are dry and peltated, or clypeated, which have tubercles of a roundish, or oblong figure, sometimes flat, sometimes convex, but never concave, nor surrounded with any rim or margin, in the manner of the scutellæ of the former kinds.

The second division of these *lichenoides* contains those which have pileated heads or pelæ, sustained on short pedicles which are fixed to their middle.

To all these there are to be added some other species, the pelæ or shields of which very rarely, if ever, appear, so that they have not yet been observed.

LICINIUM, a word used by many chirurgical writers to express a tent.

LICNON, Λικνον, in the Dionysian solemnities, the mystical van of bacchus; a thing so essential to all the solemnities of this god, that they could not be duly celebrated without it. See DIONYSIA.

LICNOPHORI, Λικνοφοροι, in the Dionysian solemnity, those who carried the LICNON.

LICTORS, among the Romans, were officers established by Romulus, who always attended the chief magistrates when they appeared in public.

The duty of their office consisted in the three following particulars: 1. *Submotio*, or clearing the way for the magistrate they attended: this they did by word of mouth; or, if there was occasion, by using the rods they always carried along with them. 2. *Animadversio*, or causing the people to pay the usual respect to the magistrate, as to alight, if on horseback, or in a chariot; to rise up, uncover, make way, and the like. 3. *Præitio*, or walking before the magistrates: this they did not confusedly, or all together, not by two or three abreast, but singly following one another in a straight line. They also preceded the triumphal car in public triumphs; and it was also part of their office to arrest criminals, and to be public executioners in beheading, &c. Their ensigns were the FASCES and SECURIS.

As to the number of *lictors* allowed each magistrate, a dictator had twenty-four, a master of the horse six, a consul twelve, a prætor six; and each vestal virgin, when she appeared abroad, had one.

LIE, or LIE *under the sea*. See LYING, &c.

LIEGE, LIGE, properly signifies a *vassal*, who holds a kind of fee, that binds him in a closer obligation to his lord than other people.

The term seems to be derived from the French *lier, to bind*; on account of a ceremony used in rendering faith, or homage; which was by locking the vassal's thumb, or his hand, in that of the lord, to shew that he was fast bound by his oath of fidelity.—Chiflet, Vignerius, and Bignon, choose rather to derive the word from the same source with *leudis*, or *leudi, legali, faithful*.—But Du-Cange falls in with the opinion of those who derive it from *lici*, a kind of vassals, so firmly attached to their lord, on account of lands or fees held of him, that they were obliged to do him all manner of service, as if they were his domestics. He adds, this was formerly called *ligium servitium*, and the person *liger*. In this sense, the word is used, Leg. Edw. cap. 19. *Fuderi sub tutela regis ligeo debent esse*; that is, wholly under his protection.

By *liege* HOMAGE, the vassal was obliged to serve his lord towards all, and against all, excepting his father. In which sense, the word was used in opposition to *simple homage*; which last only obliged the vassal to pay the rights and accustomed dues to his lord; and not to bear arms against the emperor, prince, or other superior lord: so that a *liege man* was a person wholly devoted to his lord, and entirely under his command.

Omnibus, &c. Reginaldus, rex Insulorum, salutem. Sciatis quod devenit homo ligeus domini regis Angliæ Johannis, contra omnes mortales, quamdiu vixero; & inde ei fidelitatem & sacramentum præstitit, &c. MS. penes W. Dugdale.

But it muſt be observed, there were formerly two kinds of *liege homage*: the one, by which the vassal was obliged to serve his lord, against all, without exception even of his sovereign; the other, by which he was to serve him against all, except such other lords as he had formerly owed *liege homage* to.

In our old statutes, *leges*, and *liege people*, are terms peculiarly appropriated to the king's subjects; as being *leges, legi*, or *legati*, obliged to pay allegiance to him; 8 Hen. VI. 14 Hen. VIII. &c. though private persons had their *leges* too.

Rotuulus, Dei gratia, abbas Ramesiæ, præpositis & hominibus de Brancestre, & omnibus ceteris Francis & Anglis, fidelibus.. Sciatis me dedisse terram Ulfe, in dapedani (hodie dapedale) huic Beccelmo, & uxori ejus Alfæiæ—ea conditione quod effecti sint homines leges. Lib. Ramef.

LIEGE *vaſſalage*. See VASSALAGE.

LIENIS *infarctus*. See SPLEEN.

LIENTERY, *Lientheria*, in *Phyſic*, a kind of looſeneſs or DIARRHŒA, wherein the food paſſes ſo ſuddenly through the ſtomach and guts, as to be thrown out by ſtool, with little or no alteration.

The ancients were of opinion, that the *lientery* was owing to the too great ſmoothneſs and ſlipperineſs of the inſide of the inteſtines, by which they let the food ſlip off before it was digeſted: and hence they gave it this name, which is formed from λειος, *ſmooth, poliſhed*; and εντερον, *inteſtine*.

The *lientery* is generally owing either to a defect in the ferment of the ſtomach, or to a relaxation of the pylorus, attended with ſo briſk an irritation of the fibres of the ſtomach, that, inſtead of retaining the aliment, it lets it paſs, or to an obſtruction of the inteſtinal glands.

Exceſs of drinking ſometimes occaſions this diſeaſe, by relaxing the ſtomach, and eſpecially the pylorus, too immoderately.

Emuller propoſes to ſtrengthen the ſtomach with rhubarb, quinces, and ſuch means as check vomiting: Dr. Freind adviſes to gently ſtimulate the inteſtinal tube, and to de-

terge the obſtructed glands by means of gentle purges, and vomits of ipecacuanha at proper intervals. To theſe may be added moderate riding, and ſtomachic, warm, and ſtrengthening medicines. See COELIAC *paſſion* and DYSENTERY.

LIEUTENANT, *locumtenens*, a deputy, or officer, who holds the place of a ſuperior, and diſcharges in his abſence the duties of the office which he ought to exerciſe in perſon.

Of theſe, ſome are civil; as lords *lieutenants* of kingdoms; who are the king's viceroys, and govern in his ſtead, ſuch as the lord *lieutenant* of Ireland; and LORDS *lieutenants* of counties.

But the term is moſt frequent among military men, among whom there is a variety of *lieutenants*.

LIEUTENANT is the ſecond commiſſioned officer in every company of both foot and horſe, and next to the captain, who takes the command upon the death or abſence of the captain.

LIEUTENANT *of artillery*, is an officer of the artillery, in each company of which there are one firſt and three ſecond *lieutenants*. The firſt *lieutenant* has the ſame detail of duty with the captain, becauſe in his abſence, he commands the company. The ſecond *lieutenant* is the ſame as the enſign in an infantry regiment, being the youngeſt commiſſioned officer in the company, and it is his duty to aſſiſt the firſt *lieutenant*.

LIEUTENANT *of engineers*. See ENGINEER.

LIEUTENANT-*general*, a great officer, the next in rank to the GENERAL of an army: theſe officers ſerve in the field, or in ſieges, according to the dates of their commiſſions. In battle, the oldeſt commands the right wing of the army, the ſecond the left wing, the third the centre, the fourth the right wing of the ſecond line, the fifth the left wing, the ſixth the centre, &c. In ſieges, the *lieutenant*-generals always command the right of the principal attack, and order what they think proper for the advancement of the ſiege, during the twenty-four hours they are in the trenches, except the attack, which they are not to make without an order from the general in chief.

In France they have alſo *lieutenant-generals* of their naval forces, who command immediately under the admirals.

In Holland they have a *lieutenant-admiral*, which is the ſame with what we call a *vice-admiral*.

LIEUTENANT-*general of the ordnance*, is he who has the charge of the artillery, batteries, &c. under the maſter-general, or in his abſence. This officer was firſt eſtabliſhed in 1597. See ORDNANCE.

LIEUTENANT-*colonel of foot*, is the ſecond officer in a regiment; he commands in the abſence of the COLONEL, and in battle takes poſt at his colonel's left.

The dragoons have alſo a *lieutenant-colonel*; but the horſe have not, properly, any; the firſt captain of the regiment ſupplies the office.

LIEUTENANT-*colonel of horſe*, is only the firſt captain of the regiment, who commands in the abſence of the colonel, taking place of all other captains.

LIEUTENANT-*captain*. See CAPTAIN.

This denomination was abeliſhed in the Engliſh army in 1772, when it was ordered that for the future all *captain-lieutenants* ſhould have the rank and title of captains in the army.

LIEUTENANT *of a ſhip of war*, is the officer next in rank and power to the captain, in whoſe abſence he is charged with the command of the ſhip, and alſo the execution of any orders which he may have received from the commanders relating to the king's ſervice. The *lieutenant*, who commands the watch at ſea, keeps a liſt of all the officers and men belonging to it, in order to muſter it and report to the captain the names of thoſe who are abſent from their duty. During the night-watch, he occaſionally viſits the lower deck, or ſends thither a proper officer to ſee that order is obſerved. He is always to be upon deck in his watch, to give orders for trimming the ſails and ſuperintending the navigation, and for preſerving order; but he is never to change the ſhip's courſe without the captain's direction, unleſs it be to avoid an immediate danger. In time of battle, he is to ſee, that all the men are preſent at their quarters, to order and exhort them to perform their duty, and to inform the captain of any miſbehaviour. The youngeſt *lieutenant* of the ſhip, who is alſo called *lieutenant at arms*, is, beſides his common duty, to train the ſeamen to the uſe of ſmall arms, and in time of battle to attend and direct them for this purpoſe.

LIEUTENANT *de roy*, the deputy governor of all ſtrong towns in France, who is a check upon the governor, and commands in his abſence.

LIEUTENANT *reformed* is he whoſe company or troop is broke or diſbanded, but continued in whole or half-pay, and ſtill preſerves his right of ſeniority and rank in the army.

LIFE, *vita*, is a very ambiguous term. For both God, and man, and a ſoul, and an animal, and a plant, are ſaid *to live*: yet there is not any thing common to all theſe beſides a kind of active exiſtence; which, however, is of very different kinds. See ANIMAL and VEGETABLE.

Life, then, in the general, expreſſes a kind of active, operative exiſtence; and it is therefore conceived to conſiſt in motion. But particularly,

LIFE *of body, vita corporis*, conſiſts in an uninterrupted motion therein. A body therefore, ſaid *to be living*, muſt conſiſt of various parts or members, both internal and external, ſo framed and put together, as to conſtitute one whole. And theſe members muſt be moved and warmed by ſome fluid ſubſtance, permeating the whole frame; by which heat and motion, the vital functions are to be performed. Such are nutrition, generation, local motion, &c.

LIFE *of mind, vita mentis*, is held, by the Carteſians, to conſiſt in a perpetual cogitation, or uninterrupted courſe of thinking; which ſeems likewiſe to have been Ariſtotle's meaning when he calls the ſoul ἐντελέχειαν; which his interpreters call *actus*; thinking being the only proper act of the mind.

But Mr. Locke endeavours to refute this principle. See THINKING and SOUL.

LIFE *of man, vita hominis*, conſiſts of a continued communication of body and mind; or in operations, to which both the motions of the body and ideas of the mind contribute.

Thus, e. gr. the mind now thinking of ſomething, on occaſion of that thought there ariſes a certain motion in the body: and now again, the body moves firſt, which motion is followed by ſome thought of the mind.

In ſuch alternate or reciprocal operation does the *life* of man conſiſt; conſidered as he is a compound of body and mind. See SENSATION and MOTION.

LIFE is more particularly uſed for the duration of an animal's being; or the ſpace of time that paſſeth between its birth and death.

Some contend that the *life of animals* is preſerved by the acid parts of the air mixing with the blood in the lungs; which parts diſſolve or attenuate the blood, and preſerve its heat, and by both theſe keep up the motion of the heart. See Dr. Bryan Robinſon's Treat. of the Animal Oeconomy.

LIFE is alſo uſed for the conſtitution; or, that principle of heat and motion which animates bodies, and makes them perceive, act, and grow.

In which ſenſe, *life* is divided into *animal, ſenſitive*, and *vegetative*.

LIFE, in a medical ſenſe, is defined, the CIRCULATION of the blood.

LIFE, *prolongation of*, is made, by lord Bacon, one of the three branches of medicine; the other two relating to the preſervation of health, and the cure of diſeaſes.

The theory of prolonging *life* he numbers among the deſiderata. Some means, or indications, that ſeem to lead to it, he lays down as follow.

Things are preſerved in two manners; either in their *identity*, or by *reparation*. In their *identity*, as a fly, or ant, in amber; a flower, or fruit, or wood, in a conſervatory of ſnow; a dead carcaſe, in baliams. By *reparation*, as a flame, or a mechanical engine, &c. To attain to the prolongation of *life*, both theſe methods muſt be uſed; and the human body muſt be preſerved both as immutates, as flame, and as mechanical inſtruments are preſerved.

Hence ariſe three intentions for the prolongation of *life*: *retardation* of conſumption, proper *reparation*, and *renovation* of what begins to grow old. Conſumption is occaſioned by two kinds of depredation; a depredation of the innate ſpirit, and a depredation of the ambient air. Theſe may be each prevented two ways; either by rendering thoſe agents leſs predatory, or by rendering the paſſive parts (viz. the juices of the body) leſs liable to be preyed on. The ſpirit will be rendered leſs predatory, if either its ſubſtance be condenſed, as by the uſe of opiates, grief, &c. or its quantity diminiſhed, as in ſparc and monaſtic diets; or its motion calmed, as in idleneſs and tranquility. The ambient air becomes leſs predatory, if it be either leſs heated by the rays of the ſun, as in cold climates, in caves, mountains, and anchorets cells; or be kept off from the body, as by a denſe ſkin, the feathers of birds, and the uſe of oils and unguents, without aromatics. The juices of the body are rendered leſs liable to be preyed on, either by making them harder, or more moiſt and oily: harder, as by a coarſe ſharp diet, living in the cold, robuſt exerciſes, and ſome mineral baths: moiſter, as by the uſe of ſweet foods, &c. abſtaining from ſalts and acids; and eſpecially by ſuch a mixture of drink, as conſiſts wholly of fine ſubtile particles, without any acrimony or acidity.

Reparation is performed by means of aliment; alimentation is promoted four ways; by the concoction of the viſcera, ſo as to extrude the aliment; by exciting the exterior parts to the attraction of the aliment, as in proper exerciſes and frications, and ſome unctions and baths; by the preparation of the food itſelf, ſo as it may more eaſily inſinuate itſelf, and, in ſome meaſure, anticipate the

the digestion; as in various ways of dressing meats, mixing drinks, fermenting breads, and reducing the virtues of these three into one; by promoting the act of assimilation itself, as in seasonable sleep, some external application, &c. The renovation of what begins to grow old, is performed two ways; by the intineration of the habit of the body, as in the use of emollients, emplasters, unctions, &c. of such a nature, as do not extract, but impress; or by purging off the old juices and substituting fresh ones; as in seasonable evacuations, attenuating diets, &c.

The same author adds these three axioms: that the prolongation of *life* is to be expected rather from some stated diets, than either from any ordinary regimen, or any extraordinary medicines, more from operating on the spirits, and mollifying the parts, than from the manner of feeding; and this mollifying of the parts without, is to be performed by substantials, impriments, and occlusions. See LONGÆVITY.

LIFE-ANNUITIES, are annuities the payments of which are suspended on the continuance of any given life or lives; and they may be distinguished into annuities to commence *immediately*, and annuities to commence at some future period, or *reversionary life-annuities*.

The value of a *life-annuity* is properly the sum that will be sufficient to enable a *seller* (allowing for the chances of mortality) to pay the annuity without loss; and, supposing money to bear no interest, it is always equal to the *expectation* of the life.

For example. Observations shew, that according to the *mean* probabilities of the duration of human life, the *expectation* of a life aged ten is nearly forty years; or, in other words, that a set of lives at this age, will one with another enjoy forty years each of existence, some of them enjoying a duration as much longer as others enjoy a shorter. It is obvious, there ore, that supposing money to bear no interest, 40*l.* in hand for each life, would be sufficient to enable a *seller* to pay to any number of such lives 1*l.* per *ann.* for their whole duration; or, in other words, that 40*l.* is, on this supposition, the value of a life aged ten.

But if any improvement is made of money by putting it out to interest this will be *more* than the value; because it will be more than sufficient to pay the annuity; and as much more than sufficient as the improvement or the interest is greater. If, for instance, any *sum* now in hand may be so improved, by being put out to interest, at 4 *per cent* as to double itself in eighteen years; the seller of such an annuity will (in consequence of putting out *half* the purchase-money to interest) find himself at the end of eighteen years in possession of 42*l.* or of 2*nd.* more than is sufficient to pay the remainder of the annuities, though he should make no farther improvement of the purchase-money. If he puts out the money to higher interest he will be a greater gainer, if to less, he will be a less gainer; but at any rate of interest he must be a gainer. The truth is, that supposing the interest to be that just mentioned, or 4 *per cent* and all the improvement possible made of the money at this interest, he will find 13*l.* 10*s.* 6*d.* for each annuity (instead of 40*l.*) to be sufficient to enable him to make all his payments. (See the tables at the end of this article.) But that if he improves the money at 5 *per cent.* he will find 15*l.* to be sufficient.

It may seem to follow from hence, that we have nothing to do to find the value of a *life-annuity*, but to find the *expectation* of the life, and then to take out of the common tables the value of an annuity *certain* for a term of years equal to the expectation; and it may appear strange that this should not give the true value.

The truth is, that it will give the value *greater* than it is; or that a less sum than that found in this way will be sufficient to pay the annuity. Supposing the interest 4 *per cent.* the value of an annuity certain for forty years is 19*l.* 15*s.* (See *Tab.* III. ANNUITIES) but the value of a life aged ten, at this rate of interest is, as has been just said, no more than 17*l.* 10*s.* 6*d.* The principal reason of this is the difference between the value of forty payments of an annuity to be made *every* year regularly one after another, till in forty years they are all made; and the value of the same number of payments to be made at greater distances of time from one another, and not to be all made till the end of seventy or eighty years. In this last case there is more time given for the improvement of the purchase-money, and therefore a less sum will be sufficient to enable a seller to make his payments. All that is learned from knowing the expectation of a number of lives, is the *mean* number of payments that will be made to each of them, and not the *time* in which they will be made. For example. The expectation of a *life* at ten being forty years, it follows that to a hundred lives at this age, forty payments for each *life*, or four thousand in all, will be made. But, as all the lives will not be extinct in less than seventy or eighty years, many of the payments will not be made till after the expiration of forty years; and, therefore, a part of the purchase-money will be improved for a longer time than forty years. In general, it may be observed that about a *quarter* of the payments of a set of *life-annuities* will be made after the expiration of a term of years equal to the *expectation* of the lives; and that this quarter having a longer time for accumulation than the expectations of the lives, the value of the lives must be less than the value of annuities to be paid regularly every year for a time equal to the expectation. Thus 1980*l.* will, in consequence of being improved at 4 *per cent.* pay a hundred annuities of 1*l.* for forty years. But a less sum (or 1750*l.*) will pay a hundred such annuities to a set of lives whose common expectation is forty years; because a *quarter* of the payments will not be made till after the end of forty years, and some not till after the end of seventy or eighty years; and consequently a *quarter* of the purchase-money will be improved for more than forty years, and some of it for more than seventy or eighty years.

These observations demonstrate, that it is a mistake to reckon the value of a *life-annuity* the same with the value of an annuity certain for a term of years equal to the *expectation* of the *life*. But it is a greater mistake to reckon it the same with the value of an annuity for a term certain, equal to that which a life has an even chance of existing. This is the error into which Mr. Weymar Lee, Mr. Dale, and some others have fallen. The former in particular has taken great pains to support this error in a book which is entitled, An Essay to ascertain the Value of Annuities for Years and Lives; and which affords a remarkable instance of pains misapplied and gross ignorance united to an over-bearing confidence.

The reasoning just stated is sufficient to prove this method of calculating the values of *life-annuities* to be wrong. But there is a particular consideration which sets the absurdity of it in the strongest light. Were it a right method of calculation, it would follow that an annuity on a *life* exposed to such danger in a particular year as to create an equal chance whether it will not fail in that year, would, at the beginning of the year, be worth *nothing*, though supposed to be sure of continuing for ever, if it escaped that danger.

The true method of computing the values of *life-annuities* may be explained in the following manner. Let us suppose that the duration of the annuity is to be only *one* year. That is, that 1*l.* is to be paid a year hence, provided a *life* now of a given age should be then in being. Were it *certain* that this *life* would not fail in the year, the value of the annuity would be the same with the value of it payable a year hence, or with the sum which, now put out to interest, would increase to 1*l.* in a year; and this sum, supposing interest at 4 *per cent.* is 19*s.* 2*d.* as may be seen in the table of the values of 1*l.* payable at the end of any number of years given under the article ANNUITIES.

But the payment not being to be made, should the *life* happen to fail in the year, this sum ought to be diminished in proportion to the degree of the uncertainty, which there is, whether the *life* will continue to exist through the year; and it is easy to see that this *uncertainty* or *chance* is in the proportion of the number of persons at that age living at the *end* of the year, to the number living at the *beginning* of it, as shewn by observations. For example: If it has been found in any situation that but half the number of persons of the given age living at the *beginning* of the year, are living at the end of it, the uncertainty will be as ½, and the value just mentioned ought to be lessened one half. If it appears that two-thirds or nine-tenths or ninety-nine hundredths are living at the end of the year, the same value must be diminished only one-third, one-tenth, or one hundredth. That is, it will be necessary to multiply it by ⅔ or ⅘ or ⅘⅘. Universally then, the present value of any sum to be paid a year hence, provided a given *life* should be then existing, is that sum multiplied by the value of 1*l.* payable at the end of the year (taken out of *Table* II. under the article ANNUITIES) and also by the fraction formed by making the number of the living at the age of the given *life* (taken out of the Table of *Observations*) the *denominator*, and the number of the living at the next succeeding age, (or at the end of the year) the *numerator*. For example. Let the value be sought of 1*l.* payable a year hence, if a child aged ten should be then living, reckoning interest at 4 *per cent.* The value of 1*l.* reckoning this interest and payable a year hence, is (as has been just said) 19*s.* 2*d.* or (in decimal parts of a pound, as given in the common tables of interest) .951 5 (See *Table* II. under the article ANNUITIES). The number of the living at the age of ten (in *Table* III. at the end of this article) is 56751 and at the next succeeding age

(or eleven) is 5623. It follows, therefore, that according to this table, out of 5675 living at the age of ten, only 5623 are living at the end of the year; or, in other words, that the chance or probability of a life aged ten existing through the year is as $\frac{5623}{5675}$, which fraction, therefore, multiplied by .9615 gives the value fought, or .9526 equal to 19s. 0½d.

Again, let us suppose, that the duration of a *life-annuity* of 1*l.* is to be two years, or that one payment of 1*l.* is to be made a year hence, provided a given *life* should exist a year, and a second payment of the same sum at the end of two years, provided the same life should be in existence at the end of two years. The method of finding the value of the first payment has been already explained; and by the very same reasoning it may be eafily difcovered, that the value of the fecond payment muft be the value of 1*l.* payable at the end of two years, *diminished* in proportion to the uncertainty that the given *life* will exift two years; or (which is the fame) *multiplied* by the fraction formed by making the number of the living at the given age the *denominator*, and the number of the living at the next fucceeding age but one, or at the end of two years, the *numerator*.

Example. Let the value be required of 1*l.* payable yearly for two years, provided a child aged ten fhould live two years, reckoning intereft at 4 *per cent.*

The value of the payment at the end of the firft year has been juft found to be .9526 in decimal parts of a pound, or 19s. 0½d.

The value of the payment at the end of the fecond year is the value of 1*l.* payable two years hence, leffened by the uncertainty that a life aged ten will live two years; or in the proportion of the number of the living in the table of obfervations at the age of twelve to the number of the living at the age of ten. That is, it is .9245 (the faid value of 1*l.* payable at the end of two years, taken out of *Table* II. under the article ANNUITIES) *multiplied* by the fraction $\frac{5473}{5675}$, or .9038 equal to 18s. 2d. See Table III. at the end of this article. To this value add the former value, or .9526*l.* and the total, or 1.8604*l.* will be the value of both payments, or of an annuity of 1*l.* on a *life* aged ten for two years.

By proceeding in this way it will appear that the value of the fame annuity for three years is .8889 × 1.3333 + 7.8604 = 2.725*l.* and for eighty-fix years (or the whole duration of life according to the table of obfervations) 17.5238*l.* It is evident, that in the fame method the value of an annuity of 1*l.* on a *life* at any other age is to be found; and that fuppofing the annuity any other fum than 1*l.* its value will be this fum multiplied by the value of an annuity of 1*l.*

The calculations of the values of *life-annuities* may be otherwife explained in the following manner. Suppofe a *life* annuity of 1*l.* payable yearly to every one of 5675 perfons, all now aged ten, the firft payment of which is to be made a year hence. It appears from the *Northampton* Table of Obfervations (or Table III. in the following collection of Tables) that only 5623 of thefe perfons will be living at the end of a year; and, confequently, that the money then to be paid will be only 5623*l.* The prefent value, therefore, of the firft payment of the annuities will be the fum which now put out to intereft will increafe in a year to 5623*l.* That is, it is 5623*l.* difcounted for a year, or 5406*l.* 10*s.* for this fum added to its intereft for a year (reckoned at 4 *per cent.*) will juft make up 5623*l.* From the fame Table of Obfervations, it appears farther that of 5675 perfons living at ten years of age, only 5573 will be living at the end of two years. The prefent value, therefore, of the *fecond* payment of the annuities will be the fum which being now put out to compound intereft at 4 *per cent.* will increafe to 5573*l.* in two years. This fum is 5152*l.* 4*s.* In like manner 5523, 5473, 5423, *&c.* being the number living at the end of three, four, five, *&c.* years, the value of the third, fourth, fifth, *&c.* payments of the annuities will be 5523*l.* 5473*l.* 5423*l.* *&c.* difcounted for three, four, five, *&c.* years, refpectively, and continued to the year in which all the lives become extinct. The total of all thefe values is 50443*l.* which, therefore, is the fum that would be fufficient, if improved at 4 *per cent.* to make good the payment of an annuity of 1*l.* for *life* to every one of 5675 perfons aged ten, according to the *Northampton* Table of Obfervations. The value, therefore, of fuch an annuity payable to only one of this number muft be the 5675th part of 50443*l.* or 17*l.* 10*s.* 6*d.*

In the Table of Obfervations from which the examples here given have been taken, and alfo in the Table framed by Dr. Halley, from the bills of mortality at Breflaw in Silefia, it may be obferved that the numbers dying every year out of a given number born, continue in the middle ftages of *life* nearly the fame for many years together. It was this circumftance that led Mr. De Moivre to form his hypothefis of an equal decrement of *life* through all its ftages after ten. In this hypothefis, the limit or utmoft probable extent of life is fixed to the age of eighty-fix; and out of any number living at a given age an equal number is reckoned to die every year, till at eighty-fix all the lives become extinct. Thus, for inftance, if there are feventy-fix perfons living at ten, one of them by this hypothefis will die annually during the term of feventy-fix years, at the end of which time the laft ferving *life* will have failed. Or, in other words, feventy-five will be living at the end of the firft year, feventy-four at the end of the fecond year, feventy-three at the end of the third year, and fo on for feventy-fix years; from whence it follows that the probability of one perfon's living to the end of the firft, or fecond, or third year will be $\frac{75}{76}$, $\frac{74}{76}$, $\frac{73}{76}$, *&c.* refpectively, where it appears that the fractions, and confequently the probabilities they expreſs, decreafe *arithmetically*. The number of years which a *life* wants of the age of eighty-fix is in this hypothefis called the COMPLEMENT of the *life*, and half this complement is always the EXPECTATION of the *life*. That is, according to what has been already faid, it is the number of years which one with another a fet of lives at that age will exift; or, as the writers on this fubject fometimes fpeak, it is the *fhare of life* due to each of them:

It is extremely eafy to calculate the values of *life-annuities* on this hypothefis. For, by what has been juft faid, the value of an annuity on a *life* aged 10, is the fum of the feries $\frac{75}{76} \times .9615 + \frac{74}{76} \times .9245 + \frac{73}{76} \times .8889$, &c. continued to $\frac{1}{76} \times .0527l. - .0615l. - .0245l. - .0889l.$ &c. and .0527*l.* being the values (reckoning intereft at 4 *per cent.*) of 1*l.* payable at the end of 1, 2, 3, &c. to 76 years; or, calling 1*l.* with its intereft for a year, r, and 76, n, the value of the *life* is $\frac{n-1}{nr} + \frac{n-2}{nr^2} + \frac{n-3}{nr^3} +$, &c. to $\frac{n-75}{nr^{75}}$ (See Tab. II. ANNUITIES). Now, as in this feries the probabilities of living are made to decreafe equally, the fum of it may be found at once by the following rule.

" Find in Table III. under ANNUITIES, the value of an " annuity of 1*l.* certain for a number of years equal to the " *complement*. Multiply this value by the *perpetuity* in- " creafed by unity, and divide the product by the com- " plement. The quotient fubtracted from the perpe- " tuity will be the value."

The complement in the prefent cafe being 76, the value of an annuity for 76 years being (fee Tab. III. ANNUITIES) 23.7311, and the perpetuity 25, the fum of the feries $\frac{n-1}{nr} + \frac{n-2}{nr^2} + \frac{n-3}{nr^3}$, &c. or the value of a life aged 10, will come out 16.881. In the fame manner may the value of a *life* at any other age be computed, according to this hypothefis; and thefe values are the fame with thofe in Mr. De Moivre's table of the values of lives.

But it is a neceffary obfervation, that in the firft and laft ſtages of life, this hypothefis differs too much from fact. This may be eafily feen, by comparing it with the following tables of the probabilities of human life, formed from real obfervations. The rejection of it will indeed render calculations of the values of *lives* (efpecially joint *lives*) a work of more labour and difficulty; but there is an eafy theorem given by Mr. Simpfon, in his book on the Doctrine of Annuities and Reverfions, and fince by Dr. Price, in his book on Reverfionary Payments, note (O), p. 312, 3d edit. which will remove much of this labour. We fhall here give the explanation and proof of this theorem from Mr. Morgan's Treatife on Annuities and Aſſurances, chap. ii. § 2. p. 50.

" Was it *certain* that a perſon of a given age would live " to the end of a year, the value of an annuity of 1*l.* " on fuch a life would be the prefent fum which would " increafe in a year to the value of a life one year older, " together with the value of the fingle payment of 1*l.* " to be made at the end of a year; that is, it would be " 1*l.* together with the value of a *life* aged one year " older than the given *life*, multiplied by the value of " 1*l.* payable at the end of a year. Call the value of a " *life* one year older than the given *life* N, and the va- " lue of 1*l.* payable at the end of a year $\frac{1}{r}$; then will " the value of an annuity on the given *life*, on the fup- " poſition of a *certainty* that it will exiſt a year, be " $\frac{1}{r} + \frac{1}{r} \times N$. But the fact is, that it is *uncertain* whe- " ther the given *life* will exiſt to the end of the year. " This laſt value, therefore, muſt be diminiſhed in the " proportion of this uncertainty; that is, it muſt be " multiplied by the probability that the given *life* will

" ſurvive one year; which ſuppoſing $\frac{b}{a}$ to expreſs this " probability, will make it $\frac{b}{a} \times \overline{1+N}$."

The great utility of this theorem will appear from the following examples. Suppoſe the probabilities of *life*, as they are given in the third of the following tables, or the table of obſervations for Northampton, and the rate of intereſt 4 *per cent.* or $r = 1.04$. By reaſoning in the manner already explained, the value of a *life* aged 95 will be expreſſed by the ſingle fraction $\frac{1}{2} \times .9615 = .2403$. The value of a *life* one year younger will be, by this theorem, $\frac{4}{9 \times 1.04} \times 1 + .2403 = .5300$. The value of a life two years younger, by the ſame theorem, will be $\frac{9}{16 \times 1.04} \times 1 + .5300 = .8270l.$ The value of a life three years younger, or at the age of 92, will be $\frac{16}{24 \times 1.04} \times 1 + .8270 = 1.1711.$ If we proceed in this manner, the value of every younger *life* will be deduced from that next preceding; nor will the number of multiplications neceſſary to determine the values (agreeably to any table of obſervations) of all *lives*, at all ages, much exceed the number of thoſe which muſt otherwiſe have been uſed for finding the ſingle value of the youngeſt *life*. See Tab. VIII.

Mr. Morgan, after giving this account of this theorem, and explaining a method of verifying all the operations in proceeding by it from one *life* to another, goes on to apply the theorem to the calculation of the values of joint *lives*; and, whoever will conſult this part of Mr. Morgan's Treatiſe, will be abundantly inſtructed in the beſt and moſt expeditious methods of making all calculations of this ſort.

But inſtead of following him in this, we ſhall reſume our account of the general principles on which the values of *life-annuities* are calculated. We have already explained theſe, as far as annuities on ſingle *lives* are concerned. From the ſame principles, the method of finding the value of annuities on the *joint continuance* of any two *lives*, may be underſtood. Suppoſe the ages of two perſons to be 50 and 60. It appears in Table III. that of 2857 perſons living at 50, only 2776 will live to be 51; or, in other words, that the *probability* that a perſon at this age will live a year, is $\frac{2776}{2857}$. Alſo, it appears from the ſame table, that the probability that a perſon aged 60 will live to 61, is $\frac{1874}{2038}$. The probability, therefore, that they will *both* live a year (or the former to be 51, and the latter 61) is the product of theſe two probabilities (or $\frac{2776}{2857} \times \frac{1874}{2038} = \frac{5202224}{5822566}$). For it is well known, that the probability that any two independent events will both happen, is always the product ariſing from multiplying the probability of one event by the probability of the other. See EXPECTATION.

In like manner, the probability that the former of theſe *lives* will live to be 52, 53, 54, &c. and the latter to be 62, 63, 64, &c. or that they will both live two, three, four, &c. years, is by the ſame table $\frac{2694}{2857} \times \frac{1874}{2038}$, $\frac{2612}{2857} \times \frac{1793}{2038}$, $\frac{2530}{2857} \times \frac{1712}{2038}$, &c. And according to the reaſoning already uſed, theſe probabilities multiplied by the values (in Tab. II. ANNUITIES) of *1l.* payable at the end of 1, 2, 3, 4, &c. years, will give the preſent value of the firſt, ſecond, third, fourth, &c. payments of an annuity dependent on the joint continuance of the two *lives*; and the ſum of theſe products for 1, 2, 3, 4, &c. years, will be the value of an annuity of *1l.* on the joint continuance of the two *lives* for 1, 2, 3, 4, &c. years; and if the products are continued to the extremity of the oldeſt *life*, their ſum will be the value of an annuity on the whole duration of the joint *lives*.

The values of annuities on the joint continuance of three, or any other number of *lives*, are found in a ſimilar manner. The ſeveral fractions expreſſing the reſpective probabilities of their continuing 1, 2, 3, 4, &c. years, being multiplied into one another, and alſo into *1l.* diſcounted as before; and the ſum of the products ariſing from theſe multiplications continued to 1, 2, 3, 4, &c. years, or to the extremity of the oldeſt of the *lives*, will be the values of the annuity for 1, 2, 3, 4, &c. years, or for the whole duration of the joint *lives*.

With reſpect to annuities on the *longeſt* of any number of *lives*, the reaſoning is not ſo ſimple. The following explanation, however, of the method of determining their values, when only *two* lives are concerned, will be eaſily underſtood. Suppoſe the ages of the two perſons to be 50 and 60; and for the ſake of more perſpicuity, let us ſuppoſe that the decrements of life are equal, according to Mr. De Moivre's hypotheſis, already explained. The chance of the youngeſt perſon's living one year is expreſſed by $\frac{33}{36}$; and the ſame chance with reſpect to the oldeſt by $\frac{23}{26}$. The chance of the youngeſt perſon's *not* living one year is $\frac{3}{36}$, ſubtracted from unity, or $1 - \frac{33}{36}$; and the ſame chance with regard to the oldeſt is alſo $1 - \frac{23}{26}$; for it muſt be remembered, that in the doctrine of chances, *certainty* is always denoted by *unity*; and that, conſequently, the difference between the probability of an event's happening and unity, muſt expreſs the probability of the event's *not* happening. Theſe two expreſſions, therefore, being multiplied into each other, will, according to what has been already obſerved, give the probability of their *both* dying in the year, which is equal to $1 - \frac{35}{36} - \frac{25}{26} + \frac{35 \times 25}{36 \times 26}$. For ſuppoſe the firſt fraction $1 - \frac{33}{36}$ to be multiplied into unity, it will ſtill remain equal to $1 - \frac{33}{36}$. Let it again be multiplied into $\frac{25}{26}$, and it will become equal to $\frac{25}{26} - \frac{25 \times 33}{26 \times 36}$. But $\frac{25}{26}$ was a *negative* quantity; therefore, the ſigns of the two laſt fractions muſt be changed, or they muſt be wrote down $-\frac{25}{26} + \frac{25 \times 33}{26 \times 36}$. Theſe being added to $1 - \frac{33}{36}$ will give $1 - \frac{35}{36} - \frac{25}{26} + \frac{25 \times 35}{26 \times 36}$ for the whole product of $1 - \frac{35}{36}$ into $1 - \frac{25}{26}$. Now ſince thoſe expreſſions give the probability that the two *lives* ſhall *both* fail in the year, it follows, that if they are ſubtracted from unity, they will give the probability that they ſhall *not* both fail in the year; that is, that one of them, at leaſt, will live to the end of the year. In order to ſubtract $1 - \frac{35}{36} - \frac{25}{26} + \frac{25 \times 35}{26 \times 36}$ from unity, it is evident, that nothing more is neceſſary than to change the ſigns of this expreſſion, and then add it to unity, in which caſe we ſhall have $1 - 1 + \frac{35}{36} + \frac{25}{26} - \frac{25 \times 35}{26 \times 36} = \frac{35}{36} + \frac{25}{26} - \frac{25 \times 35}{26 \times 36}$, for the true value of the above probability. In the ſame manner the chance of one of them at leaſt living to the end of the *ſecond* year, is expreſſed by $\frac{34}{36} + \frac{24}{26} - \frac{24 \times 34}{26 \times 36}$. The chance of one of them, at leaſt, living to the end of the *third* year, by $\frac{33}{36} + \frac{25}{26} - \frac{33 \times 23}{36 \times 26}$, and ſo on for a number of years equal to the complement of the youngeſt *life*, as it is plain that all the fractions will not vaniſh ſooner. If theſe ſeveral expreſſions are reſpectively multiplied into the ſum diſcounted for 1, 2, 3, &c. years, and the products are added together, we ſhall have the whole value of the annuity for the continuance of the longeſt of the two *lives*, whoſe ages are 50 and 60. By reaſoning in the ſame manner, the value of an annuity on the longeſt of *any* other two *lives*, and by any table of obſervations, may be determined. But if the values of the ſingle and joint *lives* are given, the value of an annuity during the continuance of the *longeſt* of them is immediately found; for it appears from what has been ſaid on ſingle and joint *lives*, that $\frac{25}{26}$ multiplied into *1l.* diſcounted for a year, expreſſes the value of the firſt payment of an annuity on a *life* whoſe age is 50; that $\frac{35}{36}$, multiplied into the ſame ſum, expreſſes the like value for a *life* of 60; and that $\frac{25 \times 35}{26 \times 36}$, multiplied into *1l.* expreſſes the value of the firſt payment of an annuity on the joint continuance of thoſe lives. It follows, therefore, that $\frac{35}{36} + \frac{25}{26} - \frac{25 \times 35}{26 \times 36}$ multiplied into *1l.* diſcounted for a year, and expreſſing the value of an annuity on the *longeſt* of two *lives* for one year, is equal to the difference between the value of the joint *lives*, and the *ſum* of the values of the ſingle *lives* for the ſame term. The like may be obſerved with reſpect to the *ſecond*, *third*, &c. years, from whence the general rule for finding the value of the longeſt of two *lives*, is obvious. See *Problem* VI. in the following collection of problems. See Mr. Morgan on Annuities and Aſſurances, p. 52, &c.

This account leads to an eaſy explanation of the method of finding the value of *reverſionary life-annuities* mentioned at the beginning of this article, that is of *life-annuities* which are to commence on the ſurviverſhip of one or more lives beyond others. For example: the value of an annuity on any ſingle *life* dependent on its ſurviving another ſingle *life*, and to commence at the time the ſurviverſhip takes place; or, in other words, the value of an annuity for what may happen to remain of a

single *life* after another must be the value of the *life* in expectation diminished by the value of the joint lives. For it is evident that the value of a single *life* may be divided into its value during its *joint continuance* with any other, and its value during its survivorship beyond that other *life*, and that consequently its value during its joint continuance deducted from its whole value will give its value during survivorship. See more on this subject under SURVIVORSHIP and REVERSION.

Problem I. To find the *expectation* of any given *life* according to any table of observations.

Solution. Find the sum of all the living in the table from the age of the given *life*. Divide this sum by the number of the living at that age; and the quotient lessened by half unity will be the expectation.

Example. The sum of all the living from the age of 10, in the Northampton Table of Observations (the Table III.) is 228599. This sum divided by 5675 (the number living at the age of ten) gives 40.28, which lessened by half unity, gives 39.78, or the expectation of a *life* at the age of ten according to the *Northampton* Table of Observations.

Problem II. To approximate to the value of a given *life* according to any given table of observations.

Solution. Take the difference between twice the expectation of the given *life by* the given table, and 86; and the value deduced from Mr. De Moivre's Table of the values of *lives* correfponding to that difference, provided it is not lefs than ten, will be the value of the *life*.

Example. The expectation of a *life* aged 15 is, by the Northampton Table of Observations (or Table III. in the following collection of tables) 36¼. The difference between twice this number and 86 is 13. And the value corresponding to the age of 13, in Mr. De Moivre's Table of the values of *lives* (or Table V.) is 16.604, reckoning interest at 4 *per cent.* and this is nearly the value of a *life* aged 15, by the Northampton Table.

Scholium. It muft be remembered that this rule is only an *approximation*, and fhould not be ufed except when recourfe cannot be had to tables giving the values of *lives* agreeable to given obfervations. The method of calculating fuch tables has been before particularly explained.

Problem III. To determine the value of any two joint *lives* by Mr. De Moivre's hypothefis, or on the fuppofition of an equal decrement of *life*, through all its ftages.

Solution. Referve the *difference* between the complement of the *youngeft life* and the complement of the *oldeft life* increafed by unity and by twice the perpetuity. Multiply this difference by the value of an annuity certain for a time equal to the complement of the oldeft *life*; and by this complement divide the product referving the quotient. From twice the perpetuity fubtract the referved quotient, and multiply the remainder by the perpetuity increafed by unity. This laft product divided by the complement of the *youngeft life*, and then fubtracted from the perpetuity will be the required value. *Example.* Let the joint *lives* be 10 and 15. Their complements by Mr. De Moivre's hypothefis are 76 and 71. The complement of the oldeft *life* increafed by unity and twice the perpetuity (or twice 25, reckoning intereft at 4 *per cent.*) is 122; which leffened by 76, the complement of the *youngeft life*, leaves 46 for the *referved difference*. This difference multiplied by 23.456 (the value of an annuity certain for 71 years by Table III. ANNUITIES) and the product divided by 71, (the complement of the *oldeft life*) gives 15.196, the *quotient* to be referved; which fubtracted from double the perpetuity (or from 50) and the remainder, (or 34.803) multiplied by the perpetuity increafed by unity (or by 26) gives 904.878; which, divided by 76 (the complement of the youngeft *life*) and the quotient fubtracted from the perpetuity, we have 13.097 for the value of two joint *lives* aged 10 and 15 by Mr. De Moivre's hypothefis.

By this rule, Table V. in the following collection of tables, has been computed by Dr. Price. See his Treatife on Reverfionary Payments, p. 309, and p. 328. 3d edit. There is no other table extant at prefent of the values of joint *lives* except Mr. Simpfon's for London, publifhed in his Select Exercifes, p. 266. But this table being founded on the ftate of human mortality in one of the worft of all ftreatums, or among the inhabitants of London taken in the groſs, it is by no means fitted for general ufe. The truth alfo is, as has been before obferved, that neither do the tables formed from Mr. De Moivre's hypothefis give the values of fingle and joint *lives* with the exactnefs neceffary to adapt them properly to general ufe. Being, however, the tables beſt known, and which have hitherto been moſt ufed, we have given them in the following collection of Tables, together with Mr. Simpfon's Tables for London, and one Table of the values of fingle *lives* at Northampton, calculated at an intereft of 4 *per cent.* in perfect agreement to the obfervations.

Problem IV. To determine the value of an annuity on a given *life* for any number of years.

Solution. Find the value of a *life* as many years older than the given *life* as are equal to the term for which the annuity is propofed. Multiply this value by 1*l.* payable at the end of this term, and alfo by the probability that the *life* will continue fo long. Subtract the product from the prefent value of the *life*; and the remainder multiplied by the annuity will be the anfwer.

Example. Let the annuity be 10*l.* The age of the given *life* 30 years, and the term propofed 15 years. The value of a *life* aged 45 (or 15 years older than the given *life*) appears by Table VIII. to be 12.283. The value of 1*l.* payable at the end of 15 years (by Table II. under ANNUITIES) is .5553, and the probability that the *life* will exift fo long is (by Table III. in the following collection) $\frac{11}{15}$. Thefe three quantities multiplied into each other are equal to 5.051, which being fubtracted from 14.781 (the prefent value of the given *life* by Table VIII.) we have 9.730; and this remainder multiplied into 10 (the annuity) gives 97.30*l.* for the value required.

Problem. V. To find the value of an annuity for three joint *lives*, A, B, and C.

Solution. Let A be the youngeft and C the oldeft of three propofed *lives*. Take the value of the two joint *lives* B and C, and find the age of a fingle *life* D of the fame value. Then find the value of the joint *lives* A and D, which will be the anfwer.

Example. Let the three given ages be 20, 30, and 60. The value, reckoning intereft at 4 *per cent.* of the two oldeft joint *lives* B and C (by Table VII.) is 7.779, anfwering to a fingle *life* D of 65 years (by Table VIII.) and the value of the joint *lives* A and D (by Table VII.) is 6.882, which will be the value required.

Problem VI. To find the value of the longeft of any two *lives*.

Solution. From the fum of the values of the two fingle *lives* fubtract the value of the two joint *lives*, and the remainder will be the value required.

Example. Let the ages of the two *lives* be 25 and 30, and let intereft be reckoned at 4 *per cent.* The value (by Table VI) of a *life* aged 25 is 15.315 and of a *life* aged 30 is 14.68. The fum of thefe two values is 29.99. The value of the joint *lives* is (by Table VII) 11.46; and this value fubtracted from 29.99 gives 18.53, or the value of an annuity on the longeft of the two *lives*.

Problem VII. To find the value of an annuity on the longeft of three *lives*, A, B, and C.

Solution. Let A be the youngeft, and C the oldeft of the three propofed *lives*. Find the value of the joint *lives* B and C, and find the age of a fingle *life* D of the fame value. Moreover, find by the rule in the laft problem the value of the longeft of the *lives* A and B, alfo that of the longeft of the *lives* A and C, and likewife that of the longeft of the *lives* A and D; then the laft of thefe three values fubtracted from the fum of the two former leaves the value fought.

Example. Let the three given ages be 20, 30, and 60. The value, reckoning intereft at 4 *per cent.* of the oldeft joint *lives* B and C, (by Table VII.) is 7.779 anfwering to a fingle *life* D (in Table VIII.) of 65 years. The value of the longeft of the two *lives* A and B, by the fame tables, is 18.864. Alfo that of the longeft of the two *lives* A and C is 16.941; and that of the longeft of the two *lives* A and D is 16.64. Therefore 19.165 is the value required.

Problem VIII. To find the value of an annuity granted upon three *lives*, A, B, and C, on condition of its ceafing as foon as any two of them become extinct.

Solution. Find the value of each pair of joint *lives*, viz. of A and B, of A and C, and of B and C. Then from the fum of thefe three values let twice the value of the three joint *lives* A, B and C, be deducted, and the remainder will be the anfwer.

Example. Let the ages of A, B and C, refpectively be 20, 30, and 60. By Table VII. the value of the joint *lives*

A, B } will be { 11.71
A, C } will be { 7.967
B, C } will be { 7.779

the fum of which three numbers is 27.457. Moreover the value of the three joint *lives* A, B, and C, by problem V. is 6.882; therefore 13.693 is the value required.

He that would inform himfelf more completely on this fubject fhould read the following books, *viz.* Mr. Simpfon's Doctrine of Life Annuities and Reverfions, and Select Exercifes; Mr. Morgan's Treatife on Annuities and Aſſurances; and Dr. Price on Reverfionary Payments.

TABLE I. Shewing the probability of the duration of *life* in London, deduced by Mr. Simpfon from obfervations on the bills of mortality in London for ten years, from 1728 to 1737. See this table under EXPECTATION.

TABLE II. Shewing the probabilities of the duration of *life* as deduced by Dr. Halley from the bills of mortality at Breſlaw in Sileſia.

LIFE-*annuities, payable half yearly.* Theſe are more valuable than *life-annuities* payable yearly, on the two following accounts. Firſt, the annuitant in this caſe receives one half of every payment half a year ſooner; and, ſecondly, he has the chance of receiving one half year's payment more than if he had been paid yearly. Mr. Simpſon, in his Select Exercifes, p. 283, obſerves, that the value of theſe two advantages put together (let the rate of intereſt and the number of *lives* on which the annuity depends be what they will) will always amount to $\frac{1}{4}$ of a year's purchaſe; and that if the payments are to be made *quarterly*, theſe advantages will be always worth $\frac{1}{8}$ of a year's purchaſe. But Dr. Price, in an eſſay in the Philoſophical Tranſactions, vol. lxvi. part i. p. 109, has ſtated the differences of value between *life-annuities* as they are made payable yearly, half yearly, or quarterly, with more preciſion; and from his inveſtigations it appears, that a *fifth* of a year's purchaſe is generally an addition more than ſufficient to the yearly value of an annuity, in order to obtain its value, payable half-yearly; and *three-tenths* of a year's purchaſe, in order to obtain its value, payable quarterly.

Dr. Price has given the following ſhort and eaſy theorems for finding in all caſes theſe differences of value.

Let r be (not 1*l.* with its intereſt, but merely) the intereſt of 1*l.* for a year; n the complement of a given *life*; y, h, q the values reſpectively of an annuity *certain* for n years, payable yearly, half-yearly, or quarterly; P the perpetuity; Y the preſent value of an annuity on a *life*, whoſe complement is n, payable yearly; H the value of the ſame annuity payable half-yearly; and L the value of the ſame annuity payable quarterly.

Then, $Y = P - \frac{1+r}{ry} \times y$

$$H = P - \frac{1+\frac{r}{2}}{hr} \times b$$

$$Q = P - \frac{1+\frac{r}{4}}{qr} \times q$$

Example. Let the *life* ſuppoſed be of the age of 36. The complement of ſuch a *life* is (by what has been already ſaid) 50, according to Mr. De Moivre's hypotheſis; and alſo nearly, according to Tables II. and III. in the preceding collection; therefore, n will be 50. Let the rate of intereſt be 4 *per cent.* or $r = 0.04$, $P = 25$, $Y = 21.482$ (ſee Table III. ANNUITIES) $b = 21.549$ (by the theorems given under annuities) $q = 21.582$, by the ſame theorems. Therefore,

$$Y = 25 - \frac{1.04}{50 \times 0.04} \times 21.482 = 13.829$$

$$H = 25 - \frac{1.02}{50 \times 0.04} \times 21.549 = 14.010$$

$$Q = 25 - \frac{1.01}{50 \times 0.04} \times 21.582 = 14.101$$

LIFE-*annuities ſecured by land*, differ from other *life-annuities* only in the ſingle circumſtance, that the annuitant, whenever he dies, is entitled to a payment for the time which has laplſed between the payment laſt due, and the moment of his death; whereas other annuities ſuppoſe nothing due for this time. In order to obtain the value of ſuch an annuity, $\frac{1}{2n}$ muſt be added to the expreſſion in the firſt theorem, if it is payable yearly; $\frac{1}{4n}$ muſt be added to the expreſſion in the ſecond theorem, if it is payable half-yearly; and $\frac{1}{8n}$ muſt be added to the expreſſion in the third theorem, if the annuity is payable quarterly. See Dr. Price's Eſſay, before quoted.

The value, therefore, in the laſt example of an annuity, payable *yearly* on a *life* aged 36, being 13.8295 its value, if ſecured by *land*, or to be enjoyed to the laſt moment of *life*, will be $13.829 + \frac{21.582}{100} = 14.043$; if ſecured by *land*, and payable half-yearly, its value will be $14.010 + \frac{21.549}{200} = 14.117$; if ſecured by land, and payable quarterly, its value will be $14.101 + \frac{21.582}{400} = 14.155$.

LIFE, *complement of.* See COMPLEMENT.

LIFE, *expectation of.* See EXPECTATION.

LIVES, *inſurance or aſſurance on.* See ASSURANCES *on lives.*

LIFE-*eſtate*, in our *Law*, are either for the *life* of the owner, or for the *life* of another, or others.

LIFE-*everlaſting*, a name by which the *ſiderythum*, or *gnaphalium*, of botanical writers, is ſometimes called. See CUDWEED.

LIFE-*guards.* See GUARDS.

LIFTING-*pieces*, in a clock, are thoſe parts which lift up and unlock the detents in the clock part.

LIFTS, in a ſhip, ropes belonging to the yard-arms of all yards. Their uſe is to ſtop the yard-arms, i. e. to make the end of the yards hang higher or lower, as occaſion ſerves. The top-ſail-*lifts* ſerve as ſheats for the top-gallant-yards, as well as *lifts* to the top-ſail-yards. The hauling of theſe ropes is called *topping the lifts*; thus they ſay *top a ſtarboard.* or *top a port*, i. e. haſe upon the ſtarboard or larboard *lift*.

The *lifts* for the ſprit-ſail-yard, are called *ſtanding lifts.*

LIGAMENT, in its general ſenſe, denotes any thing that ties or binds one part to another.

In which ſenſe the ancients applied the word to membranes, ſkin, fleſh, veins, and arteries; as being common *ligaments.*

LIGAMENT, in its more proper ſignification, denotes a white, tough, ſolid, inflexible part, ſerving to incloſe, and keep together, the junctures of the body.

It has no conſpicuous cavities; nor has it any ſenſe, leſt it ſhould ſuffer on the moving of the bones. It is found very different, according to the different parts where it is uſed. It is harder than a membrane, yet ſofter than a cartilage: its principal uſe is to gird and ſtrengthen the junctures, to prevent the diſlocation of the bones, and even to faſten them together, when they have no articulation. It alſo ſerves as a covering to the tendons, to ſeparate them from the muſcles, and to hold up the ſuſpended entrails, leſt their weight ſhould throw them down. Such are the *ligaments* of the liver, the bladder, and matrix.

Ligaments are of different ſubſtances; ſome hard, others ſoft, membranous, nervous, and cartilaginous; as alſo of different figures and ſituations: ſome ariſe from bones, others from cartilages, and others from membranes.

The *ligament* is held the moſt terreſtrial of all the parts of the body, after the bone and cartilage; being cold, dry, hard, and inſenſible, like them.

The principal *ligaments* of the body are the cartilaginous *ligaments*, which bind the four bones of the metacarpus with the carpus.

The *ligaments* of the ſpine are very ſtrong, being fitted to the articulations of the vertebræ, to prevent their luxation in violent motions. They are of two kinds; the one thick and fibrous, in form of a creſcent, which bind them both at top and bottom; and the other membranous, ſerving to faſten them the more ſecurely.

The *ligaments* of the liver are two in number; the firſt, called *ligamentum ſuſpenſorium*, holds it ſuſpended to the diaphragm, penetrating into the ſubſtance of the liver, to hold it the more firmly; the latter is larger, but more lax; it comes from the external coat of the liver, and is faſtened to the cartilago xiphoides. Some add a third, which is formed out of the umbilical veſſels; which, in adults, dry up, and become a *ligament*.

There are two *ligaments* belonging to the tongue; one which faſtens it, by its root, to the os hyoides; and another larger, inſerted into the middle and inferior part; this laſt is called the *frenum*, or bridle of the tongue. There are alſo *ligaments* belonging to the ſpleen.

The penis has a ſtrong *ligament*, called *ſuſpenſorium penis*, from its office in holding up the penis to the oſſa pubis; it ariſes from the fore-parts of thoſe bones, and is faſtened to the upper-part of the corpora cavernoſa penis: it has another *ligament*, which faſtens the prepuce to the glans.

The uterus has *four ligaments*; two of them called *lata, or broad*, and *two rotunda, or round*, from their figure: the broad *ligaments* are membranous, and ariſe from the proceſſes of the peritonæum, and are faſtened to the lateral parts of the bottom of the uterus; and ſerve to prevent it from falling down upon the neck, as ſometimes happens, when theſe *ligaments* are too much relaxed.

The round *ligaments* ariſe from the ſides of the womb, at the place where the tubæ Fallopianæ are joined to it. At their firſt riſe they are broad; but, by degrees, as they recede farther from the wound, grow round and ſmooth; and, as the ſpermatic veſſels do in men, paſs betwixt the duplicature of the peritonæum, and ſo out of the abdomen, through the foramina of the oblique and tranſverſe muſcles of the abdomen, and, running obliquely on the os pubis, terminate under the fat of the clitoris. By the paſſages of theſe *ligaments*, women, and girls eſpecially, are expoſed to inguinal ruptures, as men are by the paſſages of the ſpermatic veſſels.

The ſubſtance of the broad *ligaments* is membranous, looſe, and ſoft; whence ſome have compared them to the wings of a bat, and called them *alæ vespertilionum*. The round *ligaments* are of a firmer texture, and conſiſt of a double membrane, wrapping up in it veins, arteries, nerves, and lymphæducts; and both theſe, and the former have been ſometimes taken for muſcles. By theſe *ligaments* the uterus is kept ſo tight, that no violence of internal fluxes, or humours, can riſe it above its place. See *Tab. Anat. (Splanch.) fig. 9. lit. b. b. fig. 11. lit. i. i.* &c.

LIGAMENTS *of the hand*. See HAND.

LIGAMENTS *of the vertebræ*. Mr. du Vernoi has mentioned more *ligaments* of the vertebræ of the back, than are commonly deſcribed. See Comment. Acad. Petrop. tom. vi.

LIGAMENTUM *annulare*. See ANNULAR and WRIST.

LIGAMENTUM *ciliare*. See CILIARE *Ligamentum*.

LIGAMENTUM *cutaneum iſſii* (*os*) goes out anteriorly from the extremity of the os coccygis: it is very ſlender, and divides into two portions at the orifice of the anus, which run into the membrana adipoſa, and are inſerted in the ſkin on each ſide of the anus, by a kind of expanſion, and continuing to divaricate, are loſt on the two ſides of the perinæum.

LIGAMENTUM *Fallopii*. See *Ligamentum* FALLOPII and INGUINAL *Ligament*.

LIGAMENTUM *inter maxillare*, is a ligament on each ſide of the face, thus called by Winſlow. It connects the two jaws, and gives inſertion to the poſterior fibres of the buccinator muſcle. It is ſtrong and broad, fixed to the outſide of the upper jaw, above the laſt dens molaris, and at the ſide of the apophyſis pterigoidæus internus. By the lower end it is fixed on the outſide of the lower jaw, below the laſt dens molaris.

LIGAMENTUM *Poupartii*, or *Poupart's ligament*, is only the lower border of the deſcending oblique muſcle of the belly, ſtretched from the fore-part of the os ileum to the pubes.

LIGAMENTUM *pubis inter oſſium*, is a ſtrong triangular membrane, fixed by two of its edges in the inferior branches of thoſe bones, all the way up to their common ſymphyſis; the third edge, which is loweſt, is looſe, and this whole membrane, the middle of which is perforated by a particular hole, is ſtretched very tight between the two bones, and under their cartilaginous arch, to which it adheres very cloſely.

LIGAMENTUM *peculiare ſtapidis*, in *Anatomy*, a name given by Schelhammer, and ſome others, to what is properly a muſcle, and is called by Albinus *ſtapedium*, and by Cowper, and others, *muſculus ſtapidis* and *ſtapedicus*.

LIGATURE, in *Surgery*, any thing tied about a part of the body, more eſpecially a bandage, or fillet of cloth, or linen, ſerving to bind the arm, and facilitate the operation of bleeding.

They are called alſo *chords*, bands, or ſtrings, and are of different kinds, ſome fine, others coarſe and ſtrong, and are made either of flax, or hemp, or cloth, or ſilk, or horſe-hair, according to the nature of the diſorder; for theſe things are almoſt conſtantly required. They are uſed to replace or extend bones that are broken or diſlocated; to tie the patients down in lithotomy, amputations, and operations of that kind; to tie up the veins in phlebotomy; to tie up arteries after amputations, or in large wounds; to ſecure the ſplints that are applied to fractures; to tie up the proceſſes of the peritonæum, with the ſpermatic veſſels, in caſtration; and laſtly, in taking off warts, and other excreſcences by *ligature*, and in all other operations of this kind.

LIGATURE, LIGATURA, or LIGATIO, denotes alſo the act or manner of diſpoſing and applying bandages for the cloſing of wounds, and performing many of the operations in ſurgery.

LIGATURE, is alſo uſed to ſignify a kind of bandage, or fillet, tied round the neck, arm, leg, or other part of the bodies of men, or beaſts, to divert, or drive off, ſome diſeaſe, acciident, &c.

LIGATURE, among *Moſtic Divines*, ſignifies a total ſuſpenſion of the ſuperior faculties, or intellectual powers of the ſoul. They pretend, that when the ſoul is arrived at a perfect contemplation, the remains deprived of all her operations, and ceaſes to act, in order to be more ready and prepared to receive the impulſe and communications of divine grace. This paſſive ſtate of theſe contemplative people, they call their *ligature*.

LIGATURE is alſo uſed for a ſtate of impotency, in reſpect to venery, pretended to be cauſed by ſome charm, or witchcraft.

Kæmpfer tells of an uncommon kind of *ligature*, or knotting, in uſe among the people of Maſſacar, Java, Malaja, Siam, &c. By this charm, or ſpell, a man binds up a woman, and a woman a man, ſo as to put it out of their power to have to do with any other perſon; the man being thereby rendered impotent to any other woman, and all other men impotent with reſpect to the woman.

Some of their philoſophers pretend that this *ligature* may be effected by the ſhutting of a lock, the drawing of a knot, or the ſticking of a knife in the wall, at the point of time wherein the prieſt is joining a couple together; and that a *ligature*, thus effected, may be diſſolved, by the ſpouſe's urining through a ring. This piece of ſuperſtition is ſaid to obtain alſo among the Chriſtians of the Eaſt.

The ſame author tells us, that during the ceremony of marriage in Ruſſia, he obſerved an old fellow lurking behind the church-door, and mumbling over a ſtring of words; and, at the ſame time, cutting a long rod, which he held under his arm, into pieces; which, it ſeems, is a common practice at the marriages of great perſons, and done with deſign to elude and counterwork any other perſon, that might poſſibly be inducing the *ligature*.

The ſecret of inducing a *ligature*, is delivered, by the ſame author, as he was taught it on the ſpot, by one of their adepts; which, being a curioſity, we ſhall not ſcruple to add in his own words; not daring to make it ſpeak Engliſh. *Puella amantium, vel conjux magistrum ligaturus, aſſervet si concubitu actu, priusquam incidas—si feminis quantum poteſt excipiat. Hic probe cavendum ſub limine domus ſuæ in terram ſpuitat. Tu quamcito ſpuitum reliquerit, tumidum ejus baſtia in nullius prorſus quæ ſe ſanctitatis ſpecioſum obtendat, & prius ab hoc haveat cum liberis: quam ex cloaca limitari liberum ipſum introvertas, ut verſo, ut belli ſocium ligaturus, manifeſtatum ad os ſpuitum combinis; ex cunctibus cum propria urina ſubactis, ipſumque ſic ſicatum pronyi, vel, ſi cautes ſervandæ propinde non ſufficiant, eodem ſubigito cum puncto tibiæ, quem exprimenteſt. Formatum ſecum cauſæ efficatis, ſi cunque offervato hoc ſpacio, ac humectato cinereſcit. Mammilla ſi ſervaveris, omnes antes, dum ea ſiccum ſuum collimaverint, mammas conſtabescent: ipſe vero deficiet. Abrumpe hanc ſuum prius humectato, quamdiu ſe vacuabit, denuo ſuſpende, nemo prius ipſi parebit, quin & alios quotquot ſumma preparantes admiſerit.*

M. Marſhal mentions another ridiculous form of *ligature*, which he received from a brawin at Indoſtan: "If, "ſays he, the little worm in the wood lukeraa kara, be "cut into two, and the one part ſtay, and the other

" not, if the ſtirring part be bruiſed, and given with half " a beetle to a man, and the other half to a woman, the " charm will keep each from ever having to do with any " other perſon." Philoſ. Tranſ. N° 268.

LIGATURE, *ligatura*, in the *Italian Muſic*, ſignifies a tying or binding together of notes.

Hence ſyncopes are often called *ligatures*, becauſe they are made by the *ligature* of many notes. There is another ſort of *ligatures* for breves, when there are many of theſe on different lines, or in different ſpaces, to be ſung to one ſyllable.

To underſtand this, it muſt be obſerved, that only breves are capable of this ſpecies of *ligature*, becauſe their figure admits of their being placed ſo cloſe together, as to ſeem one character only, though placed on different degrees, unleſs there be occaſion to place a ſemi-circle either above or below them, to ſhew that they are tied. This kind of *ligature* regards common time only. Breves again muſt be conſidered as ſimple, as having a tail, and as being of different colours. Firſt, if they be ſimple 𝅜 and aſcend, they contain their natural quantity, i. e. each two ſemi-breves, as in example A. But if they deſcend, then each is equivalent to four ſemi-breves, if only two follow one another, as in B. If there are three or four following ones, the firſt and laſt contain each four ſemi-breves, and thoſe in the middle but two, as in C.

A B C

Secondly, if they have tails 𝅜 and the tail be turned upwards, the breves contain only one meaſure, as well aſcending as deſcending. See Ex. D. But if it be marked downwards, the breve then contains its natural quantity. See Ex. E. This ſpecies of *ligature* was invented only becauſe the minim, being round, could not be uſed in this manner. And the ſemi-circle was not at that time in uſe.

It may be here remarked, that ordinarily the firſt breve alone of every *ligature* has a tail, and that uſually placed on the left ſide. Laſtly, if they be of different colours, i. e. if the firſt be white, or open in the middle, and the ſecond black, the firſt contains a ſemibreve, and the ſecond a pointed minim. Example F.

11 11 11 41 32 32 22 22

Theſe are the principal *ligatures*, beſides which there are many others, for which ſee CHARACTER.

LIGATURES, among *Printers*, are types conſiſting of two letters or characters joined together; as *ct*, *ſt*, *ff*, *ffi*, *fl*. The old editions of Greek authors are extremely full of *ligatures*; the *ligatures* of Stephens are, by much, the moſt beautiful.

Some editions have been lately printed without any *ligatures* at all; and there was a deſign to explode them quite out of printing. Had this ſucceeded, the fineſt ancient editions would, in time, have grown uſeleſs; and the reading of old manuſcripts would have been rendered almoſt impracticable to the learned themſelves.

LIGEANCE, *ligeantia*, in *Law*, is the true and faithful obedience of a ſubject to his ſovereign; and is alſo applied to the dominion or territory of the liege lord: thus children are ſaid to be born in or out of the *ligeance* of the king, &c. Stat. 25 Edw. III.

LIGHT, that ſenſation occaſioned in the mind, by the view of luminous bodies; or that property in bodies, whereby they are fitted to excite thoſe ſenſations in us.

LIGHT is alſo uſed to denote a certain action of the luminous body, or a medium between it and the eye; by means whereof, ſome ſuppoſe the one to act on the other. This they call *ſecondary* or *derivative light*; to diſtinguiſh it from that of luminous bodies, which is called *primary*, or *innate*.

Ariſtotle explains the nature of *light*, by ſuppoſing ſome bodies to be tranſparent, as air, water, ice, &c. but ſince, in the night-time we do not ſee any thing through thoſe bodies, he ſays, they are only tranſparent potentially; whereas, in the day, they become really and actually tranſparent: and ſince it is *light* alone that can reduce that power into act, he defines *light* to be the act of a tranſparent body, conſidered as ſuch. He adds, that *light* is not fire, nor is it any thing bodily radiating from the luminous body, and tranſmitted through the tranſparent one; but the mere preſence of fire, or ſome other luminous body, at the tranſparent one.

This is Ariſtotle's doctrine of *light*, which his followers miſtaking, have charged on him another, very different; making *light* and colours to be qualities of the luminous and coloured bodies themſelves, and, in all reſpects, like thoſe ſenſations which they occaſion in us: adding, that things lucid, or coloured, could not produce any ſenſation in us, unleſs they had ſomething ſimilar in themſelves, ſince *nihil dat quod in ſe non habet*.

But the ſophiſm is apparent; for we find, that a needle, in pricking the fleſh, gives us pain, which nobody ever imagined to exiſt in the needle. But that it is not neceſſary there ſhould be any ſimilitude between the quality of the object, and the ſenſation it produces, appears ſtill more evident from a glaſs prism, which is found to exhibit blue, yellow, red, and other colours extremely vivid; and yet nobody will ſay there is any thing in the glaſs priſm like to thoſe ſenſations.

The Carteſians have reaſoned conſiderably on this notion; and own that *light*, as it exiſts in the luminous body, is nothing but a power or faculty of exciting in us a very clear and vivid ſenſation; adding, that what is required to the perception of *light*, is, that we be ſo formed, as to be capable of ſuch ſenſations; that in the hidden pores of tranſparent bodies, there be a certain ſubtile matter, which, by reaſon of its exceeding ſmallneſs, may penetrate even glaſs, and yet be ſtrong enough to ſhake certain capillaments at the bottom of the eye; and, laſtly, that this matter be impelled by the luminous body, ſo as to move the organ of ſight.

Primary *light*, therefore, they ſay, conſiſts in a certain motion of the particles of the luminous body, whereby they are enabled to propel, every way, the materia ſubtilis, lodged in the pores of tranſparent bodies; and ſecondary or derivative *light*, in a conatus to motion, or an inclination of that matter to recede from the centre of the luminous body in right lines.

Father Malebranche explains the nature of *light*, from a ſuppoſed analogy between it and ſound.

Thus he ſuppoſes all the parts of a luminous body are in a rapid motion, which, by very quick pulſes, is conſtantly compreſſing the ſubtile matter between the luminous body, and the eye, and excites vibrations of preſſion. As theſe vibrations are greater, the body appears more luminous; and as they are more quick, or more ſlow, the body is of this or that colour.

This hypotheſis, how ingenious ſoever, is now deſervedly diſcarded, ſince the great diſcoveries made by Sir Iſaac Newton, on the nature of *light*. The primary *light* they talk of, we now know, conſiſts wholly in a certain motion of the particles of the lucid body, whereby they do not propel any fictitious matter, ſuppoſed to be lodged in the hidden pores of tranſparent bodies; but threw off, from the luminous body, certain very ſmall particles, which are emitted every way with great force: and the ſecondary or derivative *light* conſiſts not in a conatus, but a real motion of theſe particles, receding every way from the luminous body, in right lines, and that with an incredible velocity.

For if *light* conſiſted in a mere preſſion, or pulſe, it would be propagated to all diſtances, in the ſame inſtant of time; the contrary of which appears, from the phænomena of the eclipſes of Jupiter's ſatellites, whoſe immerſions, as the earth approaches towards Jupiter, are found to anticipate ſomewhat on the true time, and to commence ſooner; and again, as the earth retires from Jupiter, their immerſions, which alone in that caſe can be obſerved, happen later and later, or loſe time: deviating thus very conſiderably on either ſide, from the true time marked by the tables.

This was firſt obſerved by Mr. Roemer, and ſince by other aſtronomers; the reaſon of which is not owing to any eccentricity; but does apparently follow from this, that the *light* of the ſun, reflected from the ſatellites, has farther to travel, before it reaches the eye, in the one caſe than in the other, by a ſpace equal to the diameter of the earth's annual orbit.

The obſervations, whence this concluſion was deduced, were made at the obſervatory belonging to the Royal Academy of Sciences at Paris, from 1670 to 1675: the principal fact was, that the firſt ſatellite ſometimes emerged exactly at the time calculated by the tables, and ſometimes not, ſo much that the greateſt variation was about fourteen minutes. The particular obſervation that was the moſt ſtriking was the emerſion of this ſatellite obſerved at Paris, Nov. 9, 1676, ten minutes later than it had been obſerved in the month of Auguſt, when the earth was much nearer to Jupiter. Hence Caſſini and Roemer both concluded, that this circumſtance depended on the diſtance of Jupiter with reſpect to the earth; and that, in order to account for it, they muſt ſuppoſe that the *light* was about fourteen minutes in croſſing the earth's orbit.

But the concluſion was afterwards abandoned and attacked by

by Monſieur Caſſini. Mr. Roemer's opinion found an able advocate in Dr. Halley; who removed Caſſini's difficulty, and left Mr. Roemer's concluſion in its full force. In a memoir preſented to the Academy in 1707, Monſieur Maraldi endeavoured to give a new ſtrength to Caſſini's arguments; but Monſieur Roemer's doctrine found a new defender in Mr Pound. See Phil. Tranſ. N° 326. Phil. Tranſ. abr. by Lowth. vol. i. p. 409, 422. s'Grav. Phyſ. Elem. N° 2636, ſeq.

It has been ſince found, that when the earth is between the ſun and Jupiter, his ſatellites are eclipſed about eight minutes ſooner than they could be according to the tables, and that when the earth is nearly in the oppoſite point of its orbit, theſe eclipſes happen about eight minutes later than the tables predict them. Hence it is undeniably certain, that the motion of *light* is not inſtantaneous, ſince it takes about 16½ minutes of time to go through a ſpace equal to the diameter of the earth's orbit, which is at leaſt 190 millions of miles in length; and conſequently the particles of *light* fly about 191919 miles every ſecond of time, which is near a million of miles ſwifter than the motion of a cannon-ball. And as *light* is 16½ minutes in traveling acroſs the earth's orbit, it muſt be 8¼ minutes in coming from the ſun to us; therefore, if the ſun were annihilated, we ſhould ſee him for 8¼ minutes after; and if he were again created, he would be 8¼ minutes old before we could ſee him. In order to explain this progreſſive motion of *light*, let A and B, *Tab.* III. *Optics*, *fig.* 33. be the earth in two different parts of its orbit, whoſe diſtance from each other is 95 millions of miles, equal to the earth's diſtance from the ſun S.

It is plain, that if the motion of *light* were inſtantaneous, the ſatellite 1 would appear to enter into Jupiter's ſhadow FF, at the ſame moment of time to a ſpectator in A, as to another in B. But it is now well known, that the immerſion of the ſatellite into the ſhadow is ſeen 8¼ minutes ſooner when the earth is at B, than when it is at A. As the earth moves from D to C, through the ſide AB of its orbit, it is conſtantly meeting the *light* of Jupiter's ſatellites ſooner, which occaſions an apparent acceleration of their eclipſes; and as it moves through the other half H of its orbit, from C to D, it is receding from their *light*, which occaſions an apparent retardation of their eclipſes, becauſe their *light* is then longer before it overtakes the earth. That theſe accelerations and retardations are not occaſioned by any inequality ariſing from the motions of the ſatellites in excentric orbits is plain, becauſe it affects them all alike, in whatever parts of their orbits they are eclipſed. Beſides, they go often round their orbits every year, and their motions are no way commenſurate to the earth's. Therefore a phenomenon not to be accounted for from the real motions of the ſatellites, but ſo eaſily deducible from the *motion of the* EARTH, and ſo anſwerable to it, muſt be allowed to reſult from it. And this affords one very good proof of the earth's annual motion. See the ſequel of this article.

We ſhall here obſerve, that the firſt perſon, who conceived the thought of meaſuring the velocity of *light* was Galileo, who has given a particular deſcription of his contrivance for this purpoſe, in his Treatiſe on Mechanics, p. 59. He had two men with lights, one of whom was to obſerve when the other uncovered his *light*, and to exhibit his own the moment that he perceived it: this experiment was tried, as may naturally be imagined without ſucceſs, at the diſtance of one mile; but the members of the academy Del Cimento, reſumed the experiment, and placed their obſervers to as little purpoſe, at the diſtance of two miles. However the method uſed by M. Roemer, already mentioned, was the only one adequate to the diſcovery of the velocity of *light*.

Our excellent aſtronomer, Dr. Bradley, has found nearly the ſame velocity of *light*, from his accurate obſervations, and moſt ingenious theory, to account for ſome apparent motions in the fixed ſtars. Phil. Tranſ. N° 406. or Abridg. vol. vi. p. 150. And for a ſummary account of theſe obſervations, &c. ſee STAR.

To underſtand this, it muſt be premiſed, that the fixed ſtars are luminous bodies, and at reſt, with reſpect to our planetary ſyſtem, from which they are vaſtly remote. In this ſyſtem alſo the earth is conſidered as one of the planets, and moving about the ſun.

Suppoſe the ſun repreſented in S, *Tab.* III. *Optics*, *fig.* 34. and that the circle ABCD repreſents the path of the earth, or the ecliptic. At the center S ſuppoſe a perpendicular SP raiſed to the plane of the ecliptic, and that this perpendicular paſſes through any fixed ſtar. If a ſpectator were placed in S, he would ſee the ſtar in the ſame perpendicular; but if the ſpectator paſſes over the circle ABCD, the diameter of which is ſuppoſed to bear a ſenſible though ſmall proportion to the diſtance of the ſtar, it will be perceived to change its ſituation in the heavens. For a ſpectator in A would ſee the ſtar in the line APa; in C he would ſee the ſame ſtar in the line CPc; and ſo in any other point of his progreſs; whence it follows, that the ſtar would ſeem to deſcribe a circle in the heavens repreſented by *a b c d*. If the diſtance of the ſtar was ſo very great, that in reſpect of it the diameter of the earth's orbit AC might be eſteemed a point; in this caſe, the foreſaid circle would be entirely inſenſible; all the lines drawn from the points of the orbit to the ſtar might paſs for perpendiculars to the plane of the ecliptic, and in appearance would correſpond to the ſame point in the heavens with the perpendicular in S, in which point the ſtar would always appear, if its *light* could reach us in an inſtant. But if in this caſe, where the ſtar is ſo remote, the *light* is ſuppoſed to be propagated from the ſtar with a certain velocity, at the ſame time that the earth proceeds in its orbit, the ſtar will be ſeen in an oblique direction to the plane of the orbit; becauſe of the motion compounded of the motion of *light*, and that of the ſpectator.

Suppoſe the *light* to move in the line EG (*fig.* 35.) making an angle with the line FG, in which the ſpectator is carried along; whom we ſhall conceive placed in F. Let the velocity of the ſpectator be to the velocity of the *light*, as FG to EG. While the ſpectator moves along FG, the *light* does the ſame along EG; and the particle of *light* which is in F, when the ſpectator is in F, enters the eye only when he arrives at G. Now the direction of the *light*, with reſpect to the eye, makes with the line FG the angle EFG. For if we conceive the line FE drawn, and to be carried with a parallel motion along with the eye, ſo that in reſpect thereof it be at reſt, while this continues moving, the *light* will reach the eye in the direction of the ſaid line; for when the eye ſhall be in *f*, the middle point between F and G, the tranſferred line will cut EG in its middle point *g*, to which the particle of *light* has reached, and which is likewiſe the middle point of the tranſferred line *fg*; wherefore the particle of *light*, which was in E, in the extremity of the line EF, arrives at, and will enter the eye in the direction *fg*.

Let the angle EGF (*fig.* 36.) be a right one, and EG to FG as the velocity of the *light* to the velocity of the earth in its orbit; then EFG will be the angle, which the ray of *light* entering the eye, makes with the plane in which the earth moves round the ſun.

If the earth be in B (*fig.* 37.) it moves in the direction of the tangent to its orbit in this point; that is, if we ſuppoſe the ſpectator in the ſun, the direction of the earth's motion is parallel to SC; and making the angle *a*SC equal to the angle EGF, in the former figure, the line S*a* will repreſent the line in which the ſpectator would ſee the ſtar.

In the ſame manner when the earth is in D, the ſpectator in the ſun will ſee the ſtar in S*c*, the angles PS*c* and PS*a* being equal; and the line S*a* or S*c*, by its revolution about PS, would deſcribe a cone, whoſe baſe in the heavens would be a circle repreſenting the apparent path of the ſtar through a whole year. Let us ſuppoſe this circle to be *a b c d*, as in *fig.* 37.

When the ſtar is not in the perpendicular to the plane of the ecliptic, but the line PS (*fig.* 38.) is inclined to that plane, the lines which determine the apparent motion of the ſtar in the heavens, will form cones, as in the caſes already explained; only they would be oblique, and in both caſes the apparent path of the ſtar in the heavens would be determined as above; but in this laſt caſe it would be an ellipſis, the greater diameter of which would be equal to the diameter of the circle *a b c d*, of the former figures; ſo that knowing this ellipſis, the circle might eaſily be found which the ſtar would deſcribe, if placed in the perpendicular to the plane of the ecliptic.

The only way to determine, whether the ſtars deſcribe ſuch ellipſes, is by obſervations; in making which there are great difficulties, which however Dr. Bradley has with incomparable induſtry ſurmounted.

Nothing can immediately be determined concerning the foreſaid elliptic motion. The diſtance of the ſtar from the pole of the world muſt be meaſured at different times of the year; and from the different diſtances, the elliptic motion is to be determined by calculation, allowing for the motion of the pole itſelf during the ſpace of time between the obſervations; for the pole moves in a leſſer circle, one degree of which it paſſes over in ſeventy-two years.

Dr. Bradley, making all neceſſary allowances, obſerved ſeveral ſtars at different times of the year, whereby he immediately diſcovered, that their diſtances from the pole of the world varied; and was convinced that this variation could not be attributed to the nutation of the

pole; for he examined two ſtars at equal diſtances from the pole, but ſo oppoſite, that the one ought to have receded from the pole as much as the other acceded to it, if the motion was in the pole itſelf. But this did not fall out ſo; for the change of the one ſtar was double of that of the other; a proper allowance being always made for the pole's motion ariſing from the above revolution. However, this indefatigable obſerver inferred from his obſervations, that the ſtars in certain times receded from, and acceded to, the pole of the world with a motion entirely analogous to that which is performed in an ellipſis; and alſo that they move in ſuch curves, for each of which the motion in the ſame little circle, as *abcd* (*fig.* 38.) anſwers, when the ſtars are referred to the perpendicular in S to the plane of the ecliptic; and the diameter of this minute circle for them all is 40″½.

It is plain from obſervations, to which of the above mentioned cauſes we are to aſcribe the motion of the ſtar. For if the firſt takes place, the ſtar would be carried from *a* to *c*, while the earth paſſed over the part ABC of its orbit; but this being contrary to obſervation, this cannot be the true cauſe. But this change in the ſituation of the ſtar takes place according to the obſervations, while the earth deſcribes the part BCD of its orbit, which is juſt what the ſecond cauſe requires.

If both the cauſes took place at the ſame time, the arc, deſcribed by the earth, would differ from that indicated by either of them; beſides, this concurrence of the cauſes is contrary to the obſervations; unleſs, perhaps, it may be thought reaſonable to attribute a little influence to the firſt cauſe, but ſo very ſmall a portion, as not to be ſenſibly perceived in the obſervations.

Dr. Bradley himſelf conſidered this matter in the following manner: he imagined CA (*Tab.* III. *Optics*, *fig.* 39.) to be a ray of *light* falling perpendicularly upon the line BD; that, if the eye is at reſt at A, the object muſt appear in the direction AC, whether *light* be propagated in time or in an inſtant. But if the eye is moving from B towards A, and *light* is propagated in time, with a velocity that is to the velocity of the eye as CA to BA, then *light*, moving from C to A, whilſt the eye moves from B to A, that particle of it by which the object will be diſcerned when the eye comes to A, is at C, when the eye is at B. Joining the points B, C, he ſuppoſed the line CB to be a tube, inclined to the line BD in the angle DBC, of ſuch a diameter as to admit but one particle of *light*. Then it was eaſy to conceive, that the particle of *light* at C, by which the object muſt be ſeen, when the eye, as it moves along, arrives at A, would paſs through the tube BC, if it is inclined to BD in the angle DBC, and accompanies the eye in its motion from B to A; and that it could not come to the eye placed behind ſuch a tube, if it had any other inclination to the line BD. If, inſtead of ſuppoſing CB ſo ſmall a tube, we imagine it to be the axis of a larger; then, for the ſame reaſon, the particle of *light* at C would not paſs through that axis, unleſs it is inclined to BD in the angle CBD. In like manner, if the eye moved the contrary way, from D towards A, with the ſame velocity, then the tube muſt be inclined in the angle BDC. Although, therefore, the true, or *real* place of an object is perpendicular to the line in which the eye is moving, yet the *viſible* place will not be ſo, ſince that, no doubt, muſt be in the direction of the tube; but the difference between the true and apparent place will be, *ceteris paribus*, greater or leſs, according to the different proportion between the velocity of *light* and that of the eye. So that if we could ſuppoſe that *light* was propagated in an inſtant, then there would be no difference between the real and viſible place of an object, although the eye were in motion; for in that caſe, AC being infinite with reſpect to AB, the angle ACB, the difference between the true and viſible place, vaniſhes. But if *light* be propagated in time, it is evident, from the foregoing conſiderations, that there will be always a difference between the real and viſible place of an object, unleſs the eye is moving either directly towards or from the object. And in all caſes the fine of the difference between the real and viſible place of the object will be to the fine of the viſible inclination of the object to the line in which the eye is moving, as the velocity of the eye is to the velocity of *light*.

He then ſhews, that if the earth revolve round the ſun annually, and the velocity of *light* be to the velocity of the earth's motion in its orbit, as one thouſand to one, that a ſtar really placed in the very pole of the ecliptic, would, to an eye carried along with the earth, ſeem to change its place continually; and neglecting the ſmall difference on the account of the earth's diurnal revolution on its axis, would ſeem to deſcribe a circle round that pole every way diſtant from it 3′ ½; ſo that its longitude would be varied through all the points of the ecliptic every year, but its latitude would always remain the ſame. Its right aſcenſion would alſo change, and its declination, according to the different ſituation of the ſun with reſpect to the equinoctial points, and its apparent diſtance from the north pole of the equator would be 7″ leſs at the autumnal than at the vernal equinox.

The greateſt alteration of the place of a ſtar in the pole of the ecliptic, or which, in effect, amounts to the ſame thing, the proportion between the velocity of light and the earth's motion in its orbit being known, it will not be difficult, he obſerves, to find what would be the difference, upon this account, between the true and apparent place of any other ſtar at any time; and, on the contrary, the difference between the true and apparent place being given, the proportion between the velocity of *light* and the earth's motion in its orbit may be found.

From all which the following concluſions may be deduced: 1. That the ſecond cauſe above mentioned alone takes place in this caſe, viz. that the diſtance of the ſtars is ſo great, that the diameter of the earth's orbit has no ſenſible proportion to it. 2. That the angle FEG (*fig.* 35.) in the above mentioned triangle, is 20″,2; or, ſince the apparent declination of the ſtar γ Draconis, obſerved by Dr. Bradley, on account of the ſucceſſive propagation of *light*, would be to the diameter of the little circle which a ſtar would ſeem to deſcribe about the pole of the ecliptic as 39″ to 40″,2; the half of this is the angle ACB (*fig.* 39), which is equal to 20″,2; and conſequently the ratio of EG to FG, (*fig.* 35.) or of AC to AB (*fig.* 39.) or the velocity of the *light* to the velocity of the earth in its orbit, as 10210 to 1; whence it follows, that the *light* comes from the ſun to the earth in eight minutes and twelve ſeconds. This, Dr. Bradley obſerves, is very probably the truth, becauſe it is a medium between 7 and 11, which were the times which it had before been ſuppoſed to take up, according to different obſervations of the eclipſes of Jupiter's ſatellites. Comparing his obſervations on other ſtars, he afterwards concluded, that *light* is propagated from the ſun to the earth in 8′ 13″; and the near agreement of his obſervations induced him to think, that this ſuppoſition could not differ ſo much as a ſecond of a degree from the truth; ſo that the time which *light* ſpends in paſſing from the ſun to us may be determined by theſe obſervations within 5″ or 10″, which is ſuch a degree of exactneſs as we can never hope to attain from the eclipſes of Jupiter's ſatellites. 3. That the *light* proceeds with the ſame velocity from all the ſtars; for all have the ſame angle FEG. Whence (if we ſuppoſe that all the ſtars are not equally diſtant from us, as many arguments prove) it will follow, that the motion of *light*, all the way it paſſes through the immenſe ſpace above our atmoſphere, is equable or uniform. And ſince the different methods of determining the velocity of *light* thus agree in the reſult, it is reaſonable to conclude, not only that the phenomena above recited are owing to the cauſes to which they are aſcribed, but alſo that, in the ſame medium, *light* is propagated with the ſame velocity after it has been reflected, as before. 4. Laſtly, it muſt be conſidered, that very ſmall differences cannot be perceived; and no body will deny, but that in meaſuring a ſmall angle, an error of a ſecond may be committed, whatever care is uſed to prevent it; and therefore, although we have ſaid, that the firſt cauſe is to be rejected, we do not deny that the ſtars may poſſibly by its influence deſcribe a minute circle, whoſe diameter is 1″, or even a little more. s'Graveſande Phyſ. Elem. Math. lib. ii. cap. i. p. 708, ſeq.

Hence it appears, that the ſucceſſive propagation of *light* will cauſe an *aberration* in the appearances of the ſtars, planets, and comets. After Mr. Bradley had diſcovered this cauſe of error in the apparent places of the fixed ſtars, Mr. Clairaut and others inveſtigated ſeveral rules for the computation of this aberration. Mr. Euler alſo has lately given us a paper on this ſubject. Mem. Acad. Scienc. 1756. Mr. Simpſon, in his Eſſays. Mem. de l'Acad. de Berlin, tom. ii. p. 141, ſeq.

See remarks on the effect of the aberration of *light* on the time of a tranſit of Venus over the ſun, by Dr. Price, in Phil. Tranſ. vol. lx. art. 47. p. 536.

For an account of Mr. Melville's hypotheſis of the different velocities of differently coloured rays, ſee Colour.

But to return to the hypotheſis of preſſure, by which ſome have accounted for the propagation of *light*, it may be obſerved farther, if *light* were not a body, but conſiſted in a mere preſſion, or pulſion, it would never be propagated in right lines, but would be continually inflected ad umbram. Thus Sir Iſaac Newton: "A preſſure on "a fluid medium, i. e. a motion propagated by ſuch a "medium, beyond any obſtacle, which impedes any part "of its motion, cannot be propagated in right lines, but "will be always inflecting and diffuſing itſelf every way, "to the quieſcent medium beyond that obſtacle. The "power of gravity tends downwards; but the preſſure of

" water arising from it tends every way with an equable " force, and is propagated with equal eaſe, and equal " ſtrength, in curves, as in ſtrait lines. Waves, on the " ſurface of the water, gliding by the extremes of any " very large obſtacle, inflect and dilate themſelves, ſtill " diffuſing, gradually, into the quieſcent water beyond " that obſtacle. The waves, pulſes, or vibrations of the " air, wherein ſound conſiſts, are manifeſtly inflected, " though not ſo conſiderably as the waves of water; and " ſounds are propagated with equal eaſe, through crooked " tubes, and through ſtrait lines; but *light* was never " known to move in any curve, nor to inflect itſelf ad " umbram." The rays of *light*, therefore, are ſmall corpuſcles, emitted with exceeding celerity from the luminous body. As to the force wherewith theſe corpuſcles are emitted, ſo as to enable them to move at the inconceivable rate of 11,000,000 miles in a minute; the ſame great author obſerves, " Among bodies of the ſame " kind and virtue, by how much any one is ſmaller, by " ſo much is its attractive power greater in proportion " to its bulk. This power we find ſtronger in ſmall " magnets, than in large ones, regard being had to the " difference of their weights; and the reaſon is, that the " particles of ſmall magnets, being nearer each other, " more eaſily unite their forces intimately together, and " act conjunctly. For the ſame reaſon, the rays of *light* " being of all other bodies the moſt minute, it may be " expected, that their attractive powers ſhould be, of all " others, the ſtrongeſt; and how ſtrong in effect they " are, may be gathered from the following rules: the " attraction of a ray of *light*, according to the quantity " of its matter, is, to the gravity which any projected " body has, according, likewiſe, to the quantity of its " matter, in a ratio compounded of the velocity of the " ray of *light*, to the velocity of that projected body, and " of the bending or curviture of the line, which the ray " deſcribes in the place of refraction, to the bending of " the curvature, deſcribed by that projected body; pro- " vided, however, the inclination of the ray to the re- " fracting ſurface be the ſame with that of the projected " body to the horizon. From which proportion I ga- " ther, that the attraction of the rays of *light* is above " 1,000,000,000,000,000 times greater, than the gravity " of bodies on the ſurface of the earth, in proportion to " the quantity of matter in each, if the *light* paſs from " the ſun to the earth in the ſpace of ſeven minutes. " But now, as in algebra, where affirmative quantities " ceaſe, there negative ones begin; ſo in mechanics, " where attraction ceaſes, there the repelling power muſt " ſucceed: therefore a ray of *light*, as ſoon as it is caſt " off from the luminous body, by the vibrating motion " of its parts, and is got out of the ſphere of its attrac- " tion, is propelled with an immenſe velocity."

The wonderful divifibility of the parts of matter is nowhere more apparent, than in the minuteneſs of the particles of *light*. Dr. Nieuwentyt has computed, that an inch of candle, when converted to *light*, becomes divided into 269,617,040 parts, with 40 ciphers annexed; at which rate, there muſt iſſue out of it, when burning, 418,666, with 39 ciphers more, particles in the ſecond of a minute; vaſtly more than a thouſand times a thouſand million times the number of ſands the whole earth can contain; reckoning ten inches to one foot, and that 100 ſands are equal to one inch. See Relig. Philoſ. vol. iii. p. 805.

It muſt be acknowleged, that many difficulties and objections have been urged againſt the materiality of *light*, or the hypotheſis of *light*'s conſiſting of ſmall particles emitted from luminous bodies; and that many eminent philoſophers, both foreigners and Engliſh, have recurred to the opinion, that *light* conſiſts of vibrations propagated from the luminous body, through a ſubtile ætherial medium.

The ingenious Dr. Franklin, in a letter dated April 23, 1750, expreſſes his diſſatisfaction with the doctrine, that ſuppoſes particles of matter, called *light*, continually driven off from the ſun's ſurface, with a ſwiftneſs ſo prodigious. " Muſt not, ſays he, the ſmalleſt portion " conceivable, have, with ſuch a motion, a force exceed- " ing that of a twenty-four pounder, diſcharged from a " cannon? Muſt not the ſun diminiſh exceedingly by " ſuch a waſte of matter; and the planets, inſtead of " drawing nearer to him, as ſome have fear'd, recede to " greater diſtances through the leſſened attraction? Yet " theſe particles, with this amazing motion, will not " drive before them, or remove, the leaſt and lighteſt " duſt they meet with; and the ſun appears to continue " of his ancient dimenſions, and his attendants move in " their ancient orbits." Accordingly he conjectures, that all the phenomena of *light* may be more conveniently ſolved, by ſuppoſing univerſal ſpace filled with a ſubtile elaſtic fluid, which, when at reſt, is not viſible, but whoſe vibrations affect that fine ſenſe in the eye, as thoſe of air do the groſſer organs of the ear; and that different degrees of the vibration of this medium may occaſion the appearances of different colours. The elaſtic fluid, he ſays, is always the ſame, and yet weaker and ſtronger ſparks differ in apparent colour, ſome white, blue, purple, red; the ſtrongeſt, white; the weak ones, red. Franklin's Exp. and Obſ. &c. p. 264, &c. ed. 1769.

The celebrated Mr. Euler has alſo ſtrenuouſly maintained the ſame hypotheſis, in his Theoria Lucis & Colorum. In the ſummary of his arguments againſt the common opinion, recited in Acad. Berl. 1752, p. 272. beſides the objections above mentioned, he diſputes the poſſibility, that particles of matter, allowed to move with the amazing velocity of *light*, ſhould penetrate tranſparent ſubſtances with ſo much eaſe. In whatever manner they are tranſmitted, thoſe bodies muſt have pores, diſpoſed in right lines, and in all poſſible directions, in order to form canals for the paſſage of the rays: but ſuch a ſtructure muſt take away all ſolid matter from thoſe bodies, and all coherence among their parts, if they do contain any ſolid matter.

Dr. Horſley has taken conſiderable pains to obviate the difficulties ſuggeſted by Dr. Franklin; and, ſuppoſing that the diameter of each particle of *light* does not exceed one millionth of one millionth of an inch, and that the denſity of each particle is three times that of iron, that the *light* of the ſun traverſes the ſemidiameter of the orbis magnus in 7′, and that this ſemidiameter is 21919 ſemidiameters of the earth, he calculates, that the momentum or force of motion in each particle of *light* coming from the ſun, is leſs than that in an iron ball of $\frac{1}{4}$ of an inch diameter, moving at the rate of leſs than an inch in twelve thouſand millions of millions of Egyptian years. Hence he concludes, that a particle of matter, which is probably larger than any particle of *light*, moving with the velocity of *light*, has a force of motion, which, inſtead of exceeding the force of a twenty-four pounder diſcharged from a cannon, is infinitely leſs than that of the ſmalleſt ſhot diſcharged from a pocket piſtol, or leſs than any that art can create. Moreover, he thinks it poſſible, that *light* may be produced by a continual emiſſion of matter from the ſun, without any ſuch waſte of his ſubſtance as ſhould ſenſibly contract his dimenſions, or alter the motions of the planets, within any moderate length of time. In proof of this, he obſerves, that it is not neceſſary to the production of any of the phenomena of *light*, that the emanation from the ſun ſhould be continual in a ſtrict mathematical ſenſe, or without any interval; and likewiſe that part of the *light* which iſſues from the ſun is continually returning to him by reflection from the planets, and other *light* is continually coming to him from the ſuns of other ſyſtems. He proceeds by calculation to ſhew, that in 385,130,000 Egyptian years, the ſun would loſe $\frac{1}{1000}$th of his matter, and, therefore, that the gravitation towards the ſun, at any given diſtance, would diminiſh in the ſame proportion. But this alteration is much too ſmall to diſcover itſelf in the motion of the earth, or of any of the planets. He alſo computes, that the greateſt ſtroke, which the retina of a common eye ſuſtains, when the eye, in a bright day, is turned up directly to the ſun, does not exceed that which an iron ſhot, $\frac{1}{4}$ of an inch diameter, would give, moving only at the rate of 16,16 inches in a year; but the ordinary ſtroke is leſs than the $\frac{1}{2^{64}}$th part of this. Phil. Tranſ. vol. lx. art. 35. vol. lxi. part ii. art. 50.

One of the principal difficulties attending the hypotheſis of the materiality of *light*, is the non-interference of its particles with each other. There is probably, ſays Mr. Melville, Edinb. Eſſ. vol. ii. p. 17. &c. no phyſical point in the viſible horizon, that does not ſend rays to every other point, unleſs where opaque bodies interpoſe. *Light*, in its paſſage from one ſyſtem to another, often paſſes through torrents of *light* iſſuing from other ſuns and ſyſtems, without ever interfering, or being diverted from its courſe, either by it, or by the particles of that elaſtic medium, which ſome have ſuppoſed to be diffuſed through all the mundane ſpace. In accounting for this fact, he ſuppoſes that the particles of *light* muſt be incomparably rare, even when they are the moſt denſe; that is, that the ſemidiameters of two of the neareſt particles, in the ſame, or in different beams, ſoon after their emiſſion, are incomparably leſs than their diſtance from one another. This conſideration obviates the objection urged by Euler and others againſt the materiality of *light*, from its influence in diſturbing the freedom and perpetuity of the celeſtial motions. Boſcovich and others ſolve the difficulty concerning the non-interference of the particles of *light*, by ſuppoſing that each particle is endued with an inſuperable impulſive force; but in this caſe, their ſpheres of impulſion would be more liable to interfere, and they would, on that account, be more likely to diſturb one another. This difficulty, attending the ſuppoſition, that particles of *light* move through other

light, in all imaginable directions, without perpetual collisions among the particles, and continual deflections from a rectilinear courſe, is, in a great degree, obviated, by an eaſy computation of Mr. Canton. He obſerves, that it is neceſſary to allow only a very ſmall portion of time between the emiſſion of every particle, and the next that follows in the ſame direction. Suppoſe, for inſtance, that one lucid point of the ſun's ſurface emits 150 particles in one ſecond, which are more than ſufficient to give continual *light* to the eye, without the leaſt appearance of intermiſſion; yet ſtill the particles of which it conſiſts will, on account of their great velocity, be more than a thouſand miles behind one another; and thereby leave room enough for others to paſs in all directions. Phil. Tranſ. vol. lviii. art 45. p. 344.

If we adopt the concluſions drawn from the chevalier D'Arcy's experiments on the duration of the ſenſations excited by *light*, who ſtates it at the ſeventh part of a ſecond (Hiſt. Acad. Scienc. 1765, Mem. 2.) we may admit an interval of more than 20,000 miles between each particle. Some, in order to anſwer the chief objections of this kind againſt the materiality of *light*, have adopted the hypotheſis of M. Boſcovich; who aſſumes, in his Theoria Philoſophiæ Naturalis, that MATTER is not impenetrable, but that it conſiſts of phyſical points only, endued with powers of attraction and repulſion, taking place at different diſtances; that is, ſurrounded with various ſpheres of attraction and repulſion, in the ſame manner as ſolid matter is generally ſuppoſed to be: provided, therefore, that any body move with a ſufficient degree of velocity, or have ſufficient momentum, to overcome any powers of repulſion it may meet with, it will find no difficulty in making its way through any body whatever; for nothing will interfere or penetrate one another, but powers, ſuch as we know, do, in fact, exiſt in the ſame place, and counterbalance, or over-rule one another. Prieſtley's Hiſtory, &c. of *Light*, &c. p. 391. That *light* is a real ſubſtance, notwithſtanding the objections that have been urged againſt this hypotheſis, ſeems to be eſtabliſhed by the phenomena of the Bologna ſtone, and of other ſubſtances, which poſſeſs the remarkable property of imbibing *light*, of retaining it for ſome time, and afterwards of emitting it. See PHOSPHORUS.

The doctrine of the materiality of *light* is farther confirmed by thoſe experiments, which demonſtrate, that the colour and inward texture of ſome bodies are changed, in conſequence of their being expoſed to the *light*.

The firſt obſervation of this kind appears to have been made by M. Duhamel, who found that the juice of a certain ſhell-fiſh in Provence contracted a fine purple colour when it was expoſed to the *light* of the ſun, and that the ſtronger was the *light*, the more ſplendid was the colour. Pieces of cloth dipped in this liquor, and expoſed to the ſun, became red, though they were incloſed in glaſs; but they acquired none of this colour in the ſame expoſure, if they were covered with the thineſt plates of metal. It was afterwards obſerved by Beccarius, Com. Bonon. vol. iv. p. 75. that a quantity of lana cornea, expoſed to the rays of the ſun, became of a violet colour, whilſt part of the ſame compoſition, covered with black paper, remained white. This effect was found by M. H. Schulze to depend on the ſilver that happened to be in it. Ac. Cæſar. vol. i. p. 528, &c. G. Bonzius was thus led to ſome ſubſequent experiments, which ſeem to prove, that various colours are conſiderably affected by *light*, excluſive of heat, or any thing elſe. By expoſing ribbons of different colours to the rays of the ſun, for ſeveral days, in the open air, he found that all, except the yellow and light green, loſt part of their luſtre, and were conſiderably faded; but when the ſame ribbons were expoſed to a much greater degree of heat, in a dark room, none of the colours were affected, except that a ſmall part of their luſtre was loſt; nor was any ſenſible change made in them after remaining, for a conſiderable time, in a room that faced the north. By incloſing them in an exhauſted receiver, he found that the change was not occaſioned by the air; but no change could be produced in them by the light of torches. Beccarius alſo found by experiments on paper, and a great variety of ſubſtances, mineral, vegetable, and animal, that the *light* of the ſun produced many changes in the internal ſtructure of bodies, and that thoſe ſubſtances which imbibed *light* were much injured. The ſtronger the *light*, and the longer they were expoſed to it, the more injury they received; and the injury thus ſuſtained was found to be laſting. Com. Bon. vol. vii. p. 77, &c. See Prieſtley's Hiſtory, &c. p. 378, &c.

Some writers have attempted to prove the materiality of *light*, by determining the momentum of their component particles, or by ſhewing that they had a force, ſo as, by their impulſe, to give motion to *light* bodies. M. Homberg, Ac. Par. 1708. H. p. 25, imagined, that he could not only diſperſe pieces of amianthus, and other light ſubſtances, by the impulſe of the ſolar rays, but alſo that by throwing them upon the end of a kind of level, connected with the ſpring of a watch, he could make it move ſenſibly quicker; whence, and from other experiments, was inferred the weight of the particles of *light*. But M. Du Fay, and M. Maitan, made other experiments of a more accurate kind, which exhibited no ſuch effects as M. Homberg imagined. However, Dr. Prieſtley informs us, that Mr. Michell endeavoured to aſcertain the momentum of *light* with ſtill greater accuracy, and that his endeavours were not altogether unſucceſsful. Having found that the inſtrument which he uſed, acquired, from the impulſe of the rays of *light*, a velocity of one inch in a ſecond, he inferred, that the quantity of matter contained in the rays falling upon the inſtrument at that time, amounted to no more than one twelve hundred millionth part of a grain. In the experiment, the light was collected from a ſurface of about three ſquare feet; and as this ſurface reflected only about half what falls upon it, the quantity of matter contained in the rays of the ſun, incident upon a ſquare foot and half of ſurface, in one ſecond of time, ought to be no more than the twelve hundred millionth part of a grain, or upon one ſquare foot only, the eighteen hundred millionth part of a grain. But the denſity of the rays of *light* at the ſurface of the ſun is greater than at the earth, in the proportion of 45000 to 14 there ought, therefore, to iſſue from one ſquare foot of the ſun's ſurface in one ſecond of time, in order to ſupply the waſte by *light*, one forty thouſandth part of a grain of matter; that is, a little more than two grains a day, or about four millions ſeven hundred and fifty-two thouſand grains, which is about ſix hundred and ſeventy pounds, avoirdupoiſe, in ſix thouſand years; a quantity which would have ſhortened the ſun's ſemidiameter no more than about ten feet, if it was formed of matter of the denſity of water only. Prieſtley, ubi ſupra, p. 389.

The expanſion or extenſion of any portion of *light*, is inconceivable. Dr. Hook ſhews, it is as unlimited as the univerſe; proving it from the immenſe diſtance of ſome of the fixed ſtars, the *light* whereof becomes ſenſible to the eye, by means of a teleſcope: nor, adds he, are they only the great bodies of the ſun or ſtars that are thus liable to diſperſe their *light* through the vaſt expanſe of the univerſe, but the ſmalleſt ſpark of a lucid body muſt do the ſame, even the ſmalleſt globule ſtruck from a ſteel by a flint.

The method of meaſuring the intenſity of different *lights*, or of the ſame *light* in different circumſtances, affords a curious ſubject of inveſtigation. M. Bouguer has purſued it with particular attention, and deſcribed an apparatus which he has contrived for this purpoſe, in his Traité de Optique, publiſhed at Paris in 1760. It is well known that the action of a ſtrong *light* upon the eye, and alſo the impreſſion which it leaves upon the eye, makes it inſenſible to the effect of a weaker *light*. M. Bouguer found, that when one *light* is ſixty-four times leſs than another, its preſſure or abſence will not be perceived; and, allowing for different effects on different eyes, he ſuppoſes that the boundaries, with reſpect to different perſons, may lie between ſixty and eighty. Being unable to determine the variation of the *light* of the ſun, becauſe it is too ſtrong, and that of the ſtars, becauſe it is too weak, at different altitudes, he made his obſervations on the moon, the diminution of the *light* being in the ſame proportion in this caſe and in the others, and found that its *light* at 19° 16′ is to its *light* at 66° 11′, as 1681 to 2500; or the one is nearly one third of the other. When one limb of the moon touched the horizon of the ſea, its *light* was two thouſand times leſs than at the altitude of 66° 11′. But this proportion, he ſays, is liable to variations, the atmoſphere near the ſurface of the earth varying ſo much in its denſity. Hence he concludes, that, at a medium, *light* is diminiſhed in the proportion of about 2500 to 1681, in traverſing 7469 toiſes of denſe air. He alſo found, that the center of the ſun is conſiderably more luminous than the extremities of it; whereas both the primary and ſecondary planets are more luminous at their edges than near their centers. In comparing the *lights* of the ſun and moon, he compared each of them to that of a candle in a dark room, one in the day time, and the other in the night following, when the moon was at her mean diſtance from the earth; and, after many trials, he concluded, that the *light* of the ſun is about three hundred thouſand times greater than that of the moon; and, therefore, it is no wonder that philoſophers have had ſo little ſucceſs in their attempts to collect the *light* of the moon with burning-glaſſes; for the largeſt of them will not increaſe the *light* a thouſand times, which will ſtill leave the *light* of the moon, in the focus of the mirror, three hundred times leſs than the intenſity of the common *light* of the ſun. Dr. Smith,

in

in his Optics, vol. i. p. 29, thought that he had proved, from two different conſiderations, that the *light* of the full moon would be to our day-*light* as 1 to about 90000, if no rays were loſt at the moon. His method of calculation follows, as far as it is juſt, ſays Mr. Robins, Math. Tracts, vol. ii. p. 225, directly from the propoſition for the ſame purpoſe of that excellent geometer, James Gregory, in his Geom. Par. Univerſ. p. 144; and the general propoſition there mentioned for diſtinguiſhing the proportion between the degrees of *light* received from any planet, and from the ſun repeated in David Gregory's Aſtronomy, lib. iii. prop. 58. Mr. Robins remarks, that though his eſtimate is founded on the ſuppoſition, that the moon reflects all the *light* it receives from the ſun; yet his argument is drawn from comparing the *light* of the moon ſeen in the day with the *light* of the clouds; that is, is deduced from the quantity of *light* actually reflected by the moon. In the firſt place he ſuppoſes, that the moon, enlightened by the ſun, is as luminous as the clouds are at a medium. He, therefore, ſuppoſed the *light* of the ſun to be equal to that of a whole hemiſphere of clouds, or as many moons as would cover the ſurface of the heavens. But upon this it may be obſerved, that the *light* of the ſun, ſhining perpendicularly upon any ſurface, would be equal to the *light* reflected from the whole hemiſphere, if every part of it reflected all the *light* that fell upon it; but the *light* that would, in fact, be received from the whole hemiſphere (part of it being received obliquely) would be only one half as much as would be received from the whole hemiſphere, if every part of it ſhone directly upon the ſurface to be illuminated. In his Remarks, &c. p. 17, he draws the ſame concluſion from a different method of induction; but in this caſe alſo he made a miſtake of one half, ſuppoſing all the enlightened hemiſphere of the moon to receive the direct rays of the ſun; whereas, in fact, no more can be received than would fall perpendicularly in the ſuperficial ſection of one great circle, which is juſt one half of the ſurface of the hemiſphere. Prieſtley, ubi ſupra, p. 540, &c.

Mr. Michell made this computation in a more eaſy and accurate manner. Conſidering the diſtance of the moon from the ſun, and that the denſity of the *light* muſt decreaſe in the proportion of the ſquare of that diſtance, he calculated the denſity of the ſun's *light* at that diſtance, in proportion to its denſity at the ſurface of the ſun; and in this manner he found that, if the moon reflected all the *light* it receives from the ſun, it would be only the 4500oth part of the *light* we receive from that greater luminary. Admitting, therefore, with M. Bouguer, that the moon reflects only a 300000th part of it, Mr. Michell concludes, that it reflects no more than between the ſixth and ſeventh part of the *light* that falls upon it. Phil. Tranſ. vol. lvii. art. 27, p. 234, &c.

Dr. Pemberton, in his Courſe of Chemiſtry, Lect. 2, ſtates the greateſt *light* which we can receive from the moon, when at the full, and neareſt to the earth, to exceed the *light* of the ſun more than 87,000 times, ſuppoſing that the moon reflected all the *light* of the ſun which falls upon it; but if it reflects only half the *light* that falls upon its ſurface, which is the moſt that can be ſuppoſed, then the *light* of the moon will be exceeded by the ſun's *light* more than 170,000 times; and in the mean diſtance of the moon from the earth, her *light* will be exceeded by the ſun more than 190,000 times.

Dr. s'Graveſande aſſerts, a lucid body to be, that which emits, or gives fire a motion in right lines; and makes the difference between *light* and heat to conſiſt in this, that to produce the former, the fiery particles muſt enter the eye in a rectilinear motion, which is not required in the latter: on the contrary, an irregular motion ſeems more proper for it, as appears from the rays coming directly from the ſun to the tops of mountains, which have not near that effect with thoſe in the valley, agitated with an irregular motion, by ſeveral reflexions.

Whether or no there be always *light*, where there is fire, is diſputed among authors; as alſo, whether or no there be any luminous body without heat; heat being a motion that may be infinitely diminiſhed, and *light* a matter that may be infinitely rare: to which we may add, that no heat is ſenſible to us, unleſs it be more intenſe than that of our organs of ſenſe. M. De Luc, in his Lettres Phyſiques et Morales, &c. 1780, obſerves, that the rays of the ſun, though not warm in themſelves, occaſion heat, by giving activity to a ſubſtance, which reſides in all bodies and conſtitutes a part of their maſs, and which in certain circumſtances is capable of producing heat; and that in conſequence of this influence, this ſubſtance becomes an elaſtic or igneous fluid. See HEAT.

Sir Iſaac Newton obſerves, that bodies and *light* act mutually on one another; bodies on *light*, in emitting, reflecting, refracting, and inflecting it; and *light* on bodies, by heating them, and putting their parts into a vibrating motion, wherein heat principally conſiſts. For all fixed bodies, he obſerves, when heated beyond a certain degree, do emit *light*, and ſhine; which ſhining, &c. appears to be owing to the vibrating motion of their parts; and all bodies, abounding in earthy and ſulphureous particles, if ſufficiently agitated, emit *light*, which way ſoever that agitation be effected. Thus, ſea-water ſhines in a ſtorm; quickſilver, when ſtaken in vacuo; cats, or horſes, when rubbed in the dark; and wood, fiſh, and fleſh, when putrefied.

Light proceeding from putrefecent animal and vegetable ſubſtances, as well as from glow-worms, is mentioned by Ariſtotle. Bartholin mentions four kinds of luminous inſects, two with wings, and two without; but in hot climates travellers ſay they are found in much greater numbers, and of different ſpecies. Columna, an induſtrious naturaliſt, obſerves, that their *light* is not extinguiſhed immediately upon the death of the animal. The firſt diſtinct account that occurs of *light* proceeding from putrefecent animal fleſh, is that which is given by Fabricius Ab Aquapendente in 1592. De Viſione, &c. p. 45. Bartholin gives an account of a ſimilar appearance, which happened at Montpelier in 1641, in his treatiſe De Lucc Animalium.

Mr. Boyle tells us of a piece of ſhining rotten wood, which, upon exhauſting the air from it, was extinguiſhed; but, upon its re-admiſſion, ſeemed to come to life again, and ſhone as before; being, no doubt, a real flame, and, like other flames, not to be preſerved without air. But he could not perceive that it was increaſed in condenſed air; though we have an account in Birch's Hiſt. of the Royal Society, vol. ii. p. 254, of the *light* of a ſhining fiſh, which, when the fiſh was put into a condenſing engine, was rendered more vivid by that means. The principal of Mr. Boyle's experiments were made in 1667. See his Works, vol. iii. p. 136, &c.

Whitings were the fiſh generally uſed by Mr. Boyle in his experiments; though in a diſcourſe delivered before the Royal Society in 1681, it was aſſerted, that of all fiſhy ſubſtances, the eggs of lobſters, after they had been boiled, ſhone the brighteſt. Birch's Hiſt. vol. ii. p. 70.

Mr. Boyle, in 1672, accidentally obſerved the *light* iſſuing from fleſh meat; and, among other remarks on this ſubject, he takes notice that extreme cold extinguiſhes the *light* of ſhining wood, as appeared, when a piece of it was put into a glaſs tube, and held in a frigorific mixture; probably, becauſe the extreme cold checked the putrefaction, which was the cauſe of the *light*. The ſhell-fiſh, called PHOLAS, is remarkable for its luminous quality. The *luminouſneſs of the* SEA has been alſo a ſubject of frequent obſervation. See IGNIS *fatuus*, PHOSPHORUS, and PUTREFACTION.

Mr. Hawkſbee, and many writers on the ſubject of ELECTRICITY ſince his time, have furniſhed us with a great variety of inſtances of the artificial production of *light*, by the attrition of bodies naturally not luminous; as of amber rubbed on woollen cloth in vacuo; of glaſs on woollen, of glaſs on glaſs, of oyſter-ſhells on woollen, and of woollen on woollen, all in vacuo.

On the ſeveral experiments of this kind, he makes the following reflections: that different ſorts of bodies afford remarkably different kinds of *light*, different both in colour, and in force; that the effects of an attrition are various, according to the different preparations, and managements of the bodies that are to endure it; and that bodies which have yielded a particular *light*, may be brought by friction to yield no more of that *light*.

M. Bernoulli found by experiment, that mercury amalgamated with tin, and rubbed on glaſs, produced a conſiderable *light* in the air; that gold rubbed on glaſs did it ſtill in a greater degree; but that, of all others, the moſt exquiſite *light* was that produced by the attrition of a diamond; being equally vivid with that of a burning coal briſkly agitated with the bellows.

"That the particles of *light* are attracted by thoſe of "other bodies," is evident from innumerable experiments. This phenomenon was obſerved by Sir Iſaac Newton, who found, by repeated trials, that the rays of *light* in their paſſage near the edges of bodies, whether opaque or tranſparent, as pieces of metals, the edges of knives, broken glaſſes, &c. are diverted out of the right lines, and always inflected or bent towards thoſe bodies. See INFLECTION and RAYS.

The curious obſervations that had been made on this ſubject by Dr. Hooke and Grimaldi, led Sir Iſaac Newton to repeat and diverſify their experiments, and to purſue them much farther than they had done. Having made in a piece of lead a ſmall hole with a pin, the breadth of which was the forty-ſecond part of an inch, he let into his darkened chamber, through this hole, a beam of the ſun's *light*, and found that the ſhadows of hairs, and other ſlender ſubſtances placed in it, were conſiderably broader

than they would have been, if the rays of *light* had paſſed by thoſe bodies in right lines. He, therefore, concluded, that they muſt have paſſed as they are repreſented in *Tab.* III. *Optics, fig.* 40. in which X repreſents a ſection of the hair, and AD, BE, &c. rays of *light* paſſing by at different diſtances, and then falling upon the wall QQ. Since, when the paper which receives the rays is at a great diſtance from the hair, the ſhadow is broad, it muſt follow, as he obſerves, that the hair acts upon the rays of *light* at ſome conſiderable diſtance from it; the action being ſtrongeſt on thoſe rays which are at the leaſt diſtance, and growing weaker and weaker on thoſe which are farther off, as is repreſented in the figure; and from hence it comes to paſs, that the ſhadow of the hair is much broader in proportion to the diſtance of the paper from the hair when it is nearer than when it is at a great diſtance. It is of no moment, whether the hair be ſurrounded with air, or with any other pellucid ſubſtance. The ſhadows of ſcratches made in poliſhed plates of glaſs, and the veins in the glaſs, caſt the like broad ſhadows; ſo that the breadth of ſhadow muſt proceed from ſome other cauſe than the refraction of the air.

The ſhadows of all bodies, metals, ſtones, glaſs, wood, horn, &c. in this *light*, were bordered with three parallel fringes, or bands of coloured *light*, of which that which was contiguous to the ſhadow was the broadeſt and moſt luminous, while that which was the moſt remote was the narroweſt, and ſo faint, as not eaſily to be viſible. The firſt or innermoſt fringe was violet, and deep blue next the ſhadow, light blue, green, and yellow in the middle, and red without. The ſecond fringe was almoſt contiguous to the firſt, and the third to the ſecond; and both were blue within, and yellow and red without; but their colours were very faint, eſpecially thoſe of the third. The colours, therefore, proceeded in the following order from the ſhadow: violet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The ſhadows made by ſcratches and bubbles in poliſhed plates of glaſs, were bordered with the like fringes of coloured *light*. He alſo obſerves, that by looking on the ſun through a feather, or black ribbon, held cloſe to the eye, ſeveral rainbows will appear, the ſhadows which the fibres or threads caſt on the retina being bordered with the like fringes of colours.

From comparing other experiments, in which a ray of *light* was made to paſs through a hole into a darkened chamber, and then through a hole in a paſte-board, firſt by the edge of a ſingle knife, and then by the edges of two knives placed parallel to one another, Sir Iſaac Newton concluded, that the *light* of the firſt fringe paſſed by the edge of the knife at a diſtance greater than the eight hundredth part of an inch, that the *light* of the ſecond fringe paſſed by the edge of the knife at a greater diſtance than the *light* of the firſt fringe, and that of the third at a greater diſtance than that of the ſecond; and that the *light* of which the ſtreams, obſerved in theſe experiments, conſiſted, paſſed by the edges of the knives at leſs diſtances than that of any of the fringes.

In another experiment, he placed at the hole a priſm to refract the *light*, and to form, on the oppoſite wall, the coloured image of the ſun; and he found that the ſhadows of all bodies, held in the coloured *light* between the priſm and the wall, were bordered with fringes, of the colour of that *light* in which they were held; and comparing the fringes made in the ſeveral coloured *lights*, he found, that thoſe made in the red *light* were the largeſt, thoſe made in the violet the leaſt, and thoſe made in the green were of a middle ſize. Whence he inferred, that the rays which made the fringes in the red *light*, paſſed by the hair at a greater diſtance than thoſe which made the like fringes in the violet; ſo that the hair, in cauſing theſe fringes, acted alike upon the red *light*, or leaſt refrangible rays, at a greater diſtance, and upon the violet, or moſt refrangible rays at a leſs diſtance, and thereby occaſioned fringes of different ſizes, without any change in the colour of any ſort of *light*. It may, therefore, be concluded, that when the hair in the firſt obſervation was held in the white beam of the ſun's *light*, and caſt a ſhadow, which was bordered with three fringes of coloured *light*, thoſe colours aroſe not from any new modifications impreſſed upon the rays of *light* by the hair, but only from the various inflections, whereby the ſeveral ſorts of rays were ſeparated from one another, which, before ſeparation, by the mixture of all their colours, compoſed the white beam of the ſun's *light*; but when ſeparated, compoſed *lights* of the ſeveral colours which they are originally diſpoſed to exhibit. But for a fuller account of the author's curious experiments, and the concluſions drawn from them with regard to the inflection of *light*, we muſt refer to his well known Treatiſe on Optics, *p.* 293, &c.

This action of bodies on *light* is found to exert itſelf at a ſenſible diſtance, though it always increaſes as the diſtance is diminiſhed; as appears very ſenſibly in the paſſage of a ray between the edges of two thin plates at different apertures; in which there is ſomething very peculiar; the attraction of one edge being increaſed as the other is brought nearer it. The rays of *light*, in their paſſage out of glaſs into vacuum, are not only inflected towards the glaſs, but, if they fall too obliquely, they will revert back again to the glaſs, and be totally reflected.

The cauſe of which reflexion cannot be attributed to any reſiſtance of the vacuum, but muſt be entirely owing to ſome force or power in the glaſs, which attracts or draws back the rays as they were paſſing into the vacuum. And this appears farther from hence, that if you wet the poſterior ſurface of the glaſs with water, oil, honey, or a ſolution of quickſilver, then the rays which would otherwiſe have been reflected, will paſs into and through that liquor; which ſhews that the rays are not reflected till they come to that poſterior ſurface of the glaſs, nor even till they begin to go out of it; for if at their going out they fall into any of the foreſaid mediums, they will not then be reflected, but perſiſt in their former courſe, the attraction of the glaſs being in this caſe counterbalanced by that of the liquor.

Experiments ſimilar to thoſe of Sir Iſaac Newton on inflected *light*, were proſecuted by M. Maraldi, whoſe obſervations chiefly reſpect the inflection of *light* towards other bodies, whereby their ſhadows are partially illuminated. Ac. Paris. 1723. M. p. 159. For an abſtract, ſee Prieſtley's Hiſtory, &c. of *Light*, &c. p. 521, &c.

M. Mairan, without attempting the diſcovery of new facts, endeavoured to explain the old ones, by the hypotheſis of an atmoſphere ſurrounding all bodies; and conſequently making two reflexions and refractions of *light* that impinges upon them, one at the ſurface of the atmoſphere, and the other at that of the body itſelf. This atmoſphere he ſuppoſed to be of a variable denſity, and refractive power, like the air. M. Du Tour ſucceeded Mairan, and imagined that he could account for all the phenomena by the help of an atmoſphere of an uniform denſity, and of a leſs refractive power than the air ſurrounding all bodies. Du Tour varied the Newtonian experiments, and diſcovered in the colours produced by the inflection of *light* more than three fringes, which he exhibited diſtinctly in the following manner. He took a circular board, ABED (*Tab.* III. *Optics, fig.* 41.) thirteen inches in diameter, the ſurface of which was black, except at the edge, where there was a ring of white paper, about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A ſlip of parchment three inches broad, and diſpoſed in the form of a hoop, was faſtened round the board, and pierced at the point E with a ſquare hole, each ſide being four or five lines, in order to introduce a ray of the ſun's *light*. Laſtly, in the center of the board C, and perpendicular to it, he fixed a pin, about one third of a line in diameter.

This hoop being ſo diſpoſed, that a ray of *light* entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and paſſing parallel to the plane of the board, projected the image of the ſun and the ſhadow of the pin at A.

In theſe circumſtances he obſerved, 1ſt, that quite round the concave ſurface of this hoop, there were a multitude of coloured ſtreaks; but that the ſpace mn AS, of about eighteen degrees, the middle of which was occupied by the image of the ſun, was covered with a faint *light* only.

2. The order of the colours in theſe ſtreaks was generally ſuch, that the moſt refrangible rays were the neareſt to the incident ray EC A; ſo that, beginning from the point A, the violet was the firſt, and the red the laſt colour in each of the ſtreaks. In ſome of them, however, the colours were diſpoſed in a contrary order.

3. The image of the ſun projected on each ſide of the point A, was divided by the ſhadow of the pin, which was bordered by two luminous ſtreaks.

4. The coloured ſtreaks were narrower in ſome parts of the hoop than others, and generally decreaſed in breadth in receding from the point A.

5. Among theſe coloured ſtreaks, there were ſometimes others which were white, a line, or a line and a half in breadth, which were always bordered on both ſides by a ſtreak of orange colour, at leaſt when the light of the ſun was intenſe, and the chamber ſufficiently dark.

From this experiment he thought it was evident, that the rays which paſſed beyond the pin were not the only ones that were decompoſed; for that thoſe which are reflected

back from the pin were decompofed alfo; from which he concluded, that they muft have undergone fome refraction. He alfo thought that thofe which went beyond the pin fuffered a reflexion, fo that they were all affected in a fimilar manner.

In order to account for thefe facts, our author defcribes the progrefs of a ray of *light* through an uniform atmofphere, which he fuppofes to furround the pin, and fhews that the differently refrangible rays will be feparated at their emergence from it; but he refers to fome experiments and obfervations in a future memoir, to demonftrate that all the coloured ftreaks are produced by rays that are both reflected and refracted. Memoires Preſentes, vol. v. p. 636. 641.

From other obfervations, M. Du Tour concludes, that the refracting atmofpheres, furrounding all kinds of bodies, are of the fame ſize; fay when he placed a great variety of fubftances, and of different ſizes alſo, he always found the coloured ſtreaks of the fame dimenſions. He alſo obſerves, that his hypotheſis contradicts an obſervation of Sir Iſaac Newton, viz. that thoſe rays which paſs the neareſt to any body are moſt inflected. Mem. de Mathem. & de Phyſ. vol. v. p. 630, &c. or Prieſtley, ubi ſupra, p. 53, &c.

M. Le Cat found that in ſome caſes, objects appear magnified by means of the inflection of *light*. Looking at a diſtant ſteeple, when a *wire*, of a leſs diameter than the pupil of his eye, was held pretty near to it, and drawing it ſeveral times betwixt his eye and that object, he was ſurpriſed to find that, every time the wire paſſed before his pupil, the ſteeple ſeemed to change its place, and ſome hills beyond the ſteeple ſeemed to have the ſame motion, juſt as if a lens had been drawn betwixt his eye and them. This diſcovery led him to ſeveral others depending upon the inflection of the rays of *light*. Thus, he magnified ſmall objects, as the head of a pin, by looking at them through a ſmall hole in a card; ſo that the rays which formed the image, muſt neceſſarily paſs ſo near the circumference of the hole, as to be attracted by it: he alſo exhibited other appearances of a ſimilar nature. Traité des Sens, p. 299, &c. Prieſtley, ubi ſupra, p. 537, &c.

From the mutual attraction between the particles of *light* and other bodies, ariſe two other grand phænomena, beſide the inflection of *light*, which we call the *reflexion* and *refraction* of *light*. We know that the determination of a body in motion is changed by the interpoſition of another body in its way: thus *light*, impinging on the ſurface of ſolid bodies, ſhould be turned out of its courſe, and beaten back or reflected, ſo as, like other falling bodies, to make the angle of its reflexions equal to that of incidence. This, it is found by experience, *light* does; and yet the cauſe of this effect is different from that juſt now aſſigned: the rays of *light* are not reflected by ſtriking on the very parts of the reflecting bodies, but by ſome power equably diffuſed throughout the whole ſurface of the body, whereby it acts on the *light*, either attracting or repelling it, without contact: by which ſame power, in other circumſtances, the rays are refracted; and by which alſo, the rays are firſt emitted from the luminous body; as is abundantly proved by great variety of arguments, by Sir Iſaac Newton. See Reflection and Refraction.

That great author puts it paſt doubt, that all thoſe rays which are reflected, though they approach the body infinitely near, yet never touch it; and that thoſe which do really ſtrike on the ſolid parts of bodies, adhere to them, and are as it were extinguiſhed and loſt.

If it be aſked, how it happens, ſince we aſcribe the reflexion of the rays to the action of the whole ſurface of the body without contact, that all the rays are not reflected from every ſurface; but, while ſome are reflected, others paſs through, and are refracted? the anſwer given by Sir Iſaac Newton is as follows:—Every ray of *light*, in its paſſage through any refracting ſurface, is put into a certain tranſient conſtitution or ſtate, which in the progreſs of the ray returns at equal intervals, and diſpoſes the ray at every return to be eaſily tranſmitted through the next refracting ſurface, and between the returns to be eaſily reflected by it: which alternation of reflexion and tranſmiſſion appears to be propagated from every ſurface, and to all diſtances. What kind of action or diſpoſition this is, and whether it conſiſts in a circulating or vibrating motion of the ray, or the medium, or ſomewhat elſe, he does not inquire; but allows thoſe who are fond of hypotheſes to ſuppoſe, that the rays of *light*, by impinging on any reflecting or refracting ſurface, excite vibrations in the reflecting or refracting medium, and by that means agitate the ſolid parts of the body. Theſe vibrations, thus propagated in the medium, move ſwifter than the rays, ſo as to overtake them; and when any ray is in that part of the vibration which conſpires with its motion, its velocity is increaſed, ſo that it eaſily breaks through a refracting ſurface: but when it is in a contrary part of the vibration, which impedes its motion, it is eaſily reflected; and conſequently, that every ray is ſucceſſively diſpoſed to be eaſily reflected or tranſmitted by every vibration which overtakes it. The returns of which diſpoſition of any ray to be reflected, he calls *fits of eaſy reflexion*; and thoſe of its diſpoſition to be tranſmitted, he calls *fits of eaſy tranſmiſſion*; and the ſpace between the returns, *the interval of the fits*. The reaſon, then, why the far moſt of all thoſe tranſparent bodies reflect part of the *light* incident on them, and refract the reſt, is that ſome rays at their incidence are in fits of eaſy reflection, and others of eaſy tranſmiſſion.

Light, *for the properties of reflected*. See Reflection, Mirror, &c.

Farther, a ray of *light*, paſſing out of one medium into another of different denſity, and in its paſſage making an oblique angle with the ſurface that ſeparates the mediums, will be refracted, or turned out of its right line; becauſe the rays are more ſtrongly attracted by a denſer than by a rarer medium.

That theſe rays are not refracted by ſtriking on the ſolid parts of bodies, but without any contact, by that ſame force wherewith they are emitted and reflected, exerting itſelf differently in different circumſtances, is proved in great meaſure by the ſame arguments which demonſtrate reflection to be performed without contact.

Light, *for the properties, &c. of refraction*, ſee Refraction, Lens, &c.

In *ſtained* Crystal is obſerved a kind of double refraction, very different from what we find in any other body: the rays that fall obliquely being not only diſperſed, with a double refraction in one and the ſame ſurface, but even the perpendicular rays themſelves are moſt of them divided into two beams, by means of the ſame double refraction; which beams are of the ſame colour with the incident beams, and are equal in degree of *light*, at leaſt nearly, to each other; whence the great philoſopher ſo often cited takes occaſion to ſuſpect, that there are in *light* ſome other original properties beſides thoſe hitherto deſcribed; and particularly, that the rays have different ſides, endued with ſeveral original properties.

For, of theſe refractions, the one is performed in the uſual manner, i. e. the ſine of incidence is to that of refraction as 5 is to 3; and the other in an unuſual manner: and yet the ſame ray is refracted ſometimes in the one manner, and ſometimes in the other, according to the various poſitions which its ſeveral ſides have, in reſpect to cryſtal. Theſe diſpoſitions, he ſhews, muſt have exiſted originally in the rays, without having undergone any alteration, in that reſpect, by the cryſtal.

Every ray of *light*, therefore, has two oppoſite ſides, the one originally endued with a property whereon its unuſual refraction depends, and the other not endued with that property.

Sir Iſaac Newton, having obſerved the vividly coloured image projected on the wall of a darkened room, by the ſun-beams tranſmitted through a priſm, to be five times as long as broad; ſetting himſelf to inquire into the reaſon of this diſproportion, was led from other experiments to the *experimentum crucis*; whence he diſcovered the cauſe of the phænomenon to be, that ſome of the rays of *light* were more refracted than others, and therefore exhibited ſeveral images of the ſun under the appearance of one, extended lengthwiſe.

Thence he proceeded to conclude, that *light* itſelf is an heterogeneous mixture of rays differently refrangible: and hence he diſtinguiſhes *light* into two kinds, viz. that whoſe rays are equally refrangible, which he calls *homogeneal*, *ſimilar*, or *uniform light*; and thoſe whoſe rays are unequally refrangible, which he calls *heterogeneal light*.

There are but three affections of *light*, wherein the obſerved its rays to differ, viz. refrangibility, reflexibility, and colour; and thoſe rays, which agree in refrangibility, agree alſo in the other two: whence they may be well defined homogeneal, though, in ſome other reſpects, they may poſſibly be heterogeneal.

Again, the colours exhibited by homogeneal *light*, he calls *homogeneal colours*; and thoſe produced by heterogeneal *light*, *heterogeneal colours*. Theſe definitions laid down, he advances ſeveral propoſitions.

As, firſt, that the ſun's *light* conſiſts of rays differing by indefinite degrees of refrangibility. Secondly, that rays, which differ in refrangibility, when parted from one another, do proportionably differ in the colours which they exhibit. Thirdly, that there are as many ſimple and homogeneal colours, as degrees of refrangibility; for to every degree of refrangibility belongs a different colour. Fourthly, whiteneſs, in all reſpects like that of the ſun's immediate *light*, and of the uſual objects of our ſenſes, cannot be compounded of ſimple colours, without an indefinite variety of them; for to ſuch a compoſition there are required rays endued with all the indefinite

degrees

degrees of refrangibility, which infer as many ſimple colours. Fifthly, the rays of *light*, do not act on one another in paſſing through the ſame medium. Sixthly, the rays of *light* do not ſuffer any alteration of their qualities, from refraction, nor from the adjacent quieſcent medium. Seventhly, there can no homogeneal colours be produced out of *li ht* by refraction, which are not commixed in it before: ſince refraction, as was before obſerved, changes not the qualities of the rays, but only ſeparates thoſe which have divers qualities, by means of their different refrangibility. Eighthly, the ſun's *Light* is an aggregate of homogeneal colours; whereas homogeneal colours may be called *primitive*, or *original*.

We have already obſerved, that the rays of *li ht* are compoſed of diſſimilar or heterogeneous parts: ſome of them being, in all probability, greater, others leſs. Now the leſſer the parts are, by ſo much the more refrangible they are, i. e. they are ſo much the more eaſily diverted out of the rectilineal courſe; and thoſe parts which differ in refrangibility (conſequently in bulk), he has alſo obſerved, differ in colour.

Hence ariſes the whole theory of colours; theſe parts, v. gr. which are the moſt refrangible, conſtitute a violet colour; that is, the moſt minute particles of *li ht*, when ſeparately impelled on the organ, do there excite the ſhorteſt vibrations in the retina, which are thence communicated by the ſolid part of the optic nerve into the brain, and excite in us the ſenſation of violet colour, the dulleſt and moſt languid of all colours: and thoſe particles, on the contrary, which are the leaſt refrangible, conſtitute a ray of red colour; i. e. the greateſt particles of *li ht* excite the longeſt vibrations in the retina, and ſo convey the ſenſation of a red colour, as being the moſt bright and vivid of all others. The other particles, being diſtributed into little rays, according to their reſpective magnitudes, and degrees of refrangibility, excite intermediate vibrations, and ſo occaſion ſenſations of the intermediate colours, in like manner as the vibrations of the air, according to their different magnitude, excite ſenſations of different ſounds. The colours then of theſe little rays, not being any adventitious modifications of them, but conſtant, primitive, and neceſſary properties, reſulting, in all probability from their different magnitudes, muſt be perpetual, and immutable, not to be altered by any reflection, refraction, or other ſubſequent modification.

Mr. Euler has advanced a new notion with reſpect to the origin of colours in opaque bodies: he ſuppoſed that coloured bodies reflect the ſun's incident white *light* from their anterior ſurface, but that the particular ſpecies of *light* by which they appear of different colours, is emitted by the parts of the body: e g. he imagines that vermillion does not appear red by a more copious reflection of red than of other incident rays, but by the new emiſſion of red rays, from the particular velocity of vibration, which its elaſtic parts are capable of being thrown into, by the impulſe of the incident *light*. Of this theory it is a ſufficient refutation, that no phenomena prove or require its exiſtence: beſides, according to this hypotheſis, a body of one colour placed in the homogeneous *light* of another, ought not to appear of the colour of the *light*, but of a middle one between that and its own natural colour, which is contrary to experience. Eſſays. Edi. vol. ii. p. 29.

For the doctrine of chromatics, ſee LIGHT, ſee COLOUR.

For the manner in which LIGHT *affects our ſenſes, and how it contributes to vi ion*, ſee VISION.

LIGHT *from diamonds and other bodies*. *Light* has of late ages become in a meaſure more common than it uſed to be among us. The chemical phoſphori have greatly increaſed its kinds, many electrical bodies are luminous, and many other bodies there are which are luminous without being electric.

The ancient naturaliſts, and ſince their time, ſeveral other writers, at different periods of time, have been acquainted with many of theſe properties in ſeveral bodies, though very imperfectly. They have obſerved them too carelеſsly, often exaggerated them in their accounts, and frequently deſtroyed the whole credit of the narration, by a mixture of falſity with the truth. Mr du Fay, who laboured extremely in theſe diſquiſitions, has been at the pains of collecting all the accounts of this kind from authors, and ſeparating truth and probability from what is falſe or abſurd in their accounts, has with them given many experiments of his own to the Academy of Sciences at Paris.

Among luminous bodies the DIAMOND is to be reckoned, as ſome diamonds are known to ſhine in the dark. But on account of the feebleneſs of their ſplendor, it is neceſſary for the perſon, who is to obſerve them, previouſly to ſtay in the dark at leaſt a quarter of an hour; that the pupil of the eye may be dilated and enlarged, and ſo rendered capable of receiving a larger quantity of the rays of *light*. M. du Fay has alſo obſerved, that the eyes ought to be ſhut for this time, or at leaſt one of them; and that, in that caſe, the light of the diamond is afterwards only ſeen by that eye, which has been ſhut. Before the diamond is brought into the dark room, it muſt be expoſed to the ſun-ſhine, or at leaſt to the open day-light, to imbibe a ſufficient quantity of rays; and this is done in one minute, or even leſs; eight or ten ſeconds having been found to furniſh as much *light* as a ſtone is capable of receiving: and when brought into the dark, its *light* continues about twelve or thirteen minutes, weakening all the while by inſenſible degrees. It is very remarkable, that in bodies ſo extremely ſimilar to each other as diamonds are, ſome ſhould have this property of imbibing the ſun's rays, and ſhining in the dark, and that others ſhould not; yet ſo it is found to be by experiment, and the moſt nearly reſembling ſtones ſhall be found one to have this property, and another to be deſtitute of it; while many of the moſt diſſimilar have this property in common. There ſeems to be no rule, nor even the leaſt traces of any imperfect rule of judging, which diamonds have, and which have not this property; their natural brightneſs, their purity, their ſize, or their ſhape, contribute nothing to it; and all that has been yet diſcovered of the leaſt regularity among them, is, that all the yellow diamonds have this property. This may probably ariſe from their having more ſulphur in their compoſition, and therefore illuminating more readily, or emitting a more viſible flame.

The burning of diamonds is a term uſed among the jewellers, for putting them into a fierce fire, as they frequently do, when they are ſouled with brown, or yellow, or the like; this always diveſts them of their colour, without doing them the leaſt ſenſible injury. M. du Fay, having been informed of this common practice, formed a conjecture, that the difference of diamonds in their ſhining, or not ſhining in the dark, was owing to it; and that either all thoſe which had been burnt, or all thoſe which had not, were thoſe which alone ſhone in the dark. But this was found an erroneous conjecture; for two diamonds, one lucid in the dark, the other not, were both burnt, and afterwards both were found to retain the ſame properties they had before. It is not only the open ſun-ſhine, or open day-*light*, which gives to theſe diamonds the power of ſhining in the dark; they receive it in the ſame manner, even if laid under a glaſs, or plunged in water or in milk.

Mr. du Fay tried whether it was poſſible to make the diamond retain, for any longer time, the *light* it naturally parts with ſo ſoon; and found, that if the diamond, after being expoſed to the *light*, be covered with black wax, it will ſhine in the dark, as well ſix hours afterwards, as at the time it was firſt impregnated with the *light*. Mem. Acad. Scien. Par. 1735.

The imbibing *light*, in this manner, being ſo nice a property as not to be found in ſeveral diamonds, it was not to be ſuppoſed that it would be found in any other ſtones: accordingly, on trial, the ruby, the ſapphire, and the topaz, were found wholly deſtitute of it; and among a large number of rough emeralds, one only was found to poſſeſs it. Such is the ſtrange uncertainty of theſe accidents.

All the other leſs precious ſtones were tried, and found not to poſſeſs this property of imbibing *light* from the day-*light*, or ſun-ſhine, but they all became luminous, by the different means of heating, or friction; with this difference, that ſome acquired it by one of theſe methods, and others by the other; each being unaffected by that which gave the property to the other. The diamond becomes luminous by all theſe ways.

Beccarius alſo diſcovered that diamonds have the property of the Bolognian phoſphorus, about the ſame time that it occurred to Mr. du Fay. Com. Bonon. vol. ii. p. 276. M. du Fay likewiſe obſerved, that the common topaz, when calcined had all the properties of this phoſphorus; and purſuing the diſcovery, he found the ſame property, in a great degree, in the belemnitis, gypſum, flint-ſtone, and marble. Though he was obliged to diſſolve ſome very hard ſubſtances of this kind in acids, before calcination could produce this change in them. And with ſome ſubſtances he could not ſucceed even by this means, eſpecially with flint-ſtones, river-ſand, jaſpers, agates, and rock-cryſtal. Ac. Paris, 1730. See more on the ſubject of this article under PHOSPHORUS.

LIGHT is alſo uſed to ſignify the diſpoſition of objects with regard to the receiving of *light*.

Thus we ſay, a painting is ſeen in its proper *light*, when its ſituation with regard to the *light*, is the ſame with that for which it was painted.

LIGHT, in *Sea Language*, is uſed in contradiſtinction to laden. A ſhip is accordingly called *light*, either when ſhe has no cargo, or when ſhe is not ſufficiently ballaſted.

LIGHT, in the *Manege*. A horſe is ſaid to be *light*, in French *un cheval leger*, that is a ſwift, nimble runner. We likewiſe call a horſe *light* that is well made, though he is neither ſwift nor active: for in this laſt expreſſion we conſider only the ſhape and make of a horſe, without regard to his qualities.

Light upon the hand; a horſe is ſaid to be ſuch, that has a good tractable mouth, and does not reſt too heavy upon the bit.

A coach-horſe is ſaid to be *light*, when he ſtirs nimbly, and dreads the whip; or when he has a *light* trot.

LIGHT-*hand*. See HAND.

LIGHT-*bellied*, in the *Manege*. A horſe is thus called that commonly has flat, narrow, contracted ſides, which makes the flank turn up like that of a grey-hound.

LIGHTS, in *Architecture*, denote doors, windows, and other places, through which the air and *light* have a paſſage.

In the PANTHEON, all the *lights* comes from on high; it has no *lights* but in the dome.

LIGHTS, *ſtopping of a houſe*, is a nuiſance; but ſtopping a proſpect is not, being only matter of delight, not of neceſſity. If a man has a vacant piece of ground, and builds thereupon a houſe, with good *lights*, which he ſells or lets to another; and afterwards builds upon ground contiguous, or lets the ſame to another perſon, who builds thereupon, to the nuiſance of the *lights* of the firſt houſe; the leſſee of the firſt houſe may have an action of the caſe againſt ſuch builder, &c. And though formerly they were to be *lights* of an ancient meſſuage, that is now altered.

LIGHTS, in *Painting*, are thoſe parts of a piece which are illuminated, or that lie open to the luminary by which the piece is ſuppoſed to be enlightened; and which, for this reaſon, are painted in bright vivid colours.

In this ſenſe, *light* is oppoſed to *ſhadow*.

Different *lights* have very different effects on a picture, and occaſion a difference in the management of every part. A great deal therefore depends on the painter's chuſing a proper *light* for his piece to be illuminated by; and a great deal more, in the conduct of the *lights* and ſhadows, when the luminary is pitched upon.

The ſtrength and relievo of a figure, as well as its gracefulneſs, depend entirely on the management of the *lights*, and the joining of thoſe to the ſhadows.

The *light* a figure receives is either direct or reflected; to each of which ſpecial regard muſt be had. The doctrine of lights and ſhadows makes that part of painting called CLAIR-*obſcure*.

LIGHTS, *ſcaff of*. See DEDICATION.

LIGHT is alſo uſed for the luminous body that emits it. There are various kinds of *lights*; *general lights*, as the air; *particular lights*, as a fire, a candle, and even the ſun.

LIGHT-*horſe*, an ancient term in our Engliſh cuſtoms, ſignifying an ordinary cavalier, or horſeman lightly armed, and ſo as to enter a corps or regiment; in oppoſition to the men at arms, who were heavily accoutred, and armed at all points. See *Light*-HORSE.

LIGHT-*houſe*, is erected upon a cape or promontory on the ſea-coaſt, or upon ſome rock in the ſea, and having a great fire, or *light* formed by candles, upon its top, in the night time, which is conſtantly attended by ſome careful perſon, ſo as to be ſeen at a great diſtance from the land. It is uſed to direct the ſhipping on the coaſt, that might otherwiſe run aſhore, or ſteer an improper courſe when the darkneſs of the night, and the uncertainty of currents, &c. might render their ſituation, with regard to the ſhore, extremely doubtful. Lamp-lights are, on many accounts, preferable to coal-fires or candles; and the effect of theſe may be increaſed by placing them either behind glaſs-hemiſpheres, or before properly diſpoſed glaſs or metal reflectors. See an account of the *light-houſes* at Liverpool, in their preſent improved ſtate, in Hutchinſon's Treatiſe on Practical Seamanſhip, 4to. 1777. See BEACONS.

LIGHT-*room*, is a ſmall apartment incloſed with glaſs windows, near the magazine of a ſhip of war. It is uſed to contain the lights by which the gunner and his aſſiſtants are enabled to fill the cartridges with powder, to be ready for action.

LIGHTEN, in the *Manege*. To *lighten* a horſe, or make him *light* in the fore-hand, is to make him freer and *lighter* in the fore-hand than behind. If you would have your horſe *light*, you ought to keep him always diſpoſed to a gallop, when you put him to a trot; and after galloping ſome time, you ſhould put him back to the trot again.

LIGHTER, a large open veſſel, generally managed with oars; common on the river Thames; where it is uſed for the carriage of timber, coals, ballaſt, and any goods to or from a ſhip, when the is to be laden or delivered. There are alſo ſome *lighters* furniſhed with a deck throughout, in order to contain thoſe merchandizes, which would be damaged in rainy weather: theſe are uſually called cloſe-*lighters*.

LIGHTER-*man*. See COMPANY.

LIGHTNESS. See LEVITY.

LIGHTNING, in *Phyſology*, is a large, bright flame, darting ſwiftly through the air, and extending every way to a conſiderable diſtance, of momentary duration, and commonly attended with THUNDER. Some have accounted for this phenomenon by ſuppoſing, that, from the particles of ſulphur, nitre, and other combuſtible matter, which are exhaled from the earth, and carried into the higher regions of the atmoſphere, is formed an inflammable ſubſtance, which, when a ſufficient quantity of fiery particles is ſeparated from the vapour buoyed up into the air, with theſe particles adhering to them, by the colliſion of two clouds or otherwiſe, takes fire, and ſhoots out into a train of light, larger or leſs, according to the ſtrength and quantity of the materials. Others have explained *lightning* by the fermentation of ſulphureous ſubſtances with nitrous acids: ſee THUNDER. But in the preſent advanced ſtate of the ſcience of ELECTRICITY, this is univerſally allowed to be an electrical phenomenon. Philoſophers had not proceeded far in their experiments and inquiries on this ſubject, before they were ſtruck with the obvious analogy between *lightning* and electricity, and they produced many arguments, *a priori*, to aſcertain their ſimilarity. But the method of verifying this hypotheſis was firſt propoſed by Dr. Franklin, who, towards the cloſe of the year 1749, conceived the practicability of drawing *lightning* from the clouds: having found, by previous experiments, that the electric fluid is attracted by points, he apprehended, that *lightning* might likewiſe poſſeſs the ſame property; though the effects of the latter muſt, in an aſtoniſhing degree, ſurpaſs thoſe of the former. The other circumſtances of reſemblance between *lightning* and electricity remarked by this ingenious philoſopher, and abundantly confirmed by later diſcoveries are the following: flaſhes of *lightning*, he obſerved, are generally ſeen crooked and waving in the air; and the electric ſpark drawn from an irregular body at ſome diſtance, and when it is drawn by an irregular body or through a ſpace in which the beſt conductors are diſpoſed in an irregular manner, always exhibits the ſame appearance.

Lightning ſtrikes the higheſt and moſt pointed objects in its way, preferable to others, as high hills, trees, ſpires, maſts of ſhips, &c. and all pointed conductors receive and throw off the electric fluid more readily than thoſe which are terminated by flat ſurfaces. *Lightning* is obſerved to take the readieſt and beſt conductor; and this is the reaſon why electricity in the diſcharge of the LEYDEN phial; whence the doctor infers, that in a thunder ſtorm, it would be ſafer to have one's cloaths wet than dry. *Lightning* burns, diſſolves metals (ſee FUSION), rends ſome bodies, has been often known to ſtrike people blind, deſtroys animal life, deprives magnets of their virtue and reverſes their poles; and theſe are well-known properties of electricity.

Lightning not only gives polarity to the magnetic needle, but to all bodies, that have any thing of iron in them, as brick, &c. and by obſerving which way the poles of theſe bodies lie, it may be known, with the utmoſt certainty, in what direction the ſtroke paſſed. Signior Beccaria ſuppoſes, that perſons are ſometimes killed by *lightning*, without being really touched by it; a vacuum of air only being ſuddenly made near them, and the air ruſhing out of their lungs to ſupply it; and with ſo much violence that they could never recover their breath. In proof of this opinion he alledges, that the lungs of ſuch perſons are found flaccid; whereas, when they are properly killed by the electric ſhock, the lungs are found inflated: but this hypotheſis is controverted by Dr. Prieſtley. In order to demonſtrate the identity of the electric fluid with the matter of *lightning*, by actual experiment, Dr. Franklin contrived to bring *lightning* from the heavens, by means of an electrical kite, which he raiſed, when a ſtorm of thunder was perceived to be coming on; and with the electricity thus obtained, he charged phials, kindled ſpirits, and performed all other electrical experiments, which are uſually exhibited by an excited globe or tube. This happened in June, 1752, a month after the electricians in France, of whom the moſt active were Meſſrs. Dalibard and Delor, followed by Mr. Mazeas and M. Monnier, perfoing the method which he had propoſed, had verified the ſame theory; but without any knowledge of what they had done. In April and June, 1753, he diſcovered that the air was ſometimes electriſied poſitively, and ſometimes negatively, and found that the clouds would change from poſitive to negative electricity ſeveral times in the courſe of one thunder-guſt. He

ſoon

soon perceived that this important discovery, was capable of being applied to practical use, and proposed a method which he soon accomplished, of securing buildings from being damaged by *lightning*, by means of CONDUCTORS. The English philosophers had not been less attentive to this subject than their neighbours on the continent; but for want of proper opportunities for trying the necessary experiments, and from some incidental circumstances that were unfavourable, they had failed of success. However, in July, 1752, Mr. Canton succeeded; and in the following month, Mr. Wilson and Dr. Bevis observed nearly the same appearances which Mr. Canton had observed before. Mr. Canton also soon after observed, in a number of experiments, that some clouds were in a positive and some in a negative state of electricity; and that the electricity of his conductor would sometimes change from one state to the other, five or six times in less than half an hour. This variable state of thunder clouds was discovered by S. Beccaria, before he heard of its having been observed by Dr. Franklin or any other person; and he has given a very exact and circumstantial account of the external appearances of these clouds. From his observations of the *lightning* abroad, and of his apparatus within doors, he inferred, that the quantity of electric matter, in an usual storm of thunder, is almost inconceivably great, considering how many pointed bodies, as trees, spires, &c. are perpetually drawing it off, and what a prodigious quantity is repeatedly discharged to or from the earth. This quantity is so great, that he thinks it impossible for any cloud or number of clouds to contain it all, so as either to discharge or receive it. Besides, he observes, that, during the progress and increase of the storm, though the *lightning* frequently struck to the earth, the same clouds were the next moment ready to make a still greater discharge, and his apparatus continued to be as much affected as ever; and, therefore, the clouds must have received at one place, in the same moment when a discharge was made from them in another: and, upon the whole, he infers, that the clouds serve as conductors to convey the electric fluid from those places of the earth that are overloaded with it, to those which are exhausted of it. This electric matter, the rise of which, from the earth into the higher regions of the atmosphere, is ascertained by the great quantities of sand, ashes, and other light substances, carried up with it, and scattered uniformly over a large tract of country, wherever it issues, attracts to it, and bears up with it the watery particles that are dispersed in the atmosphere. It ascends into the higher regions of the atmosphere, being solicited by the less resistance it finds there than in the common mass of the earth, which, at these times, is generally very dry, and consequently highly electric. The same cause which first raised a cloud, from vapours dispersed in the atmosphere, draws to it those that are already formed, and continues to form new ones, till the whole collected mass extends so far as to reach a part of the earth where there is a deficiency of the electric fluid. Thither too, will those clouds, replete with electricity, be strongly attracted, and there will the electric matter discharge itself upon the earth: a channel of communication being, in this manner, formed, a fresh supply of electric matter will be raised from the overloaded part, and will continue to be conveyed by the medium of the clouds, till the equilibrium of the fluid between the two places of the earth be restored. When the clouds are attracted in their passage by those parts of the earth, where there is a deficiency of the fluid, those detached fragments are formed, and also those uniform descending protuberances, which are, in some cases, the cause of water-SPOUTS and HURRICANES.

That the electric matter, which forms and animates the thunder-clouds, issues from places far below the surface of the earth, and that it buries itself there, is probable from the deep holes, that have, in many places, been made by *lightning*; and from the flashes that have been seen to arise from subterraneous cavities and from wells; as well as from the inundations accompanying thunder-storms, and occasioned by water bursting out of the bowels of the earth. The greatest difficulty attending this theory of the origin of thunder-storms relates to the collection and insulation of electric matter within the body of the earth. With respect to the former, this ingenious philosopher has nothing to say; some operations in nature are certainly attended with a loss of the equilibrium in the electric fluid, but no person has yet assigned a more probable cause of the redundancy of the electric matter, which, in fact, often abounds in the clouds, than what we may suppose possible to take place in the bowels of the earth: and supposing the loss of the equilibrium possible, the same cause that produced the effect, would prevent the restoring of it; so that not being able to force a way, at least one sufficiently ready, through the body of the earth, it would issue at the most convenient vent into the higher regions of the air, as the better passage. S. Beccaria observes, that a wind always blows from the place from which the thunder-cloud proceeds; and it is certain, that the sudden congregation of such a prodigious quantity of vapours must displace the air, and repel it on all sides. A great number of observations relating to the descent of *lightning*, confirm his theory of the manner of its ascent; for, in many cases, it throws before it the parts of conducting bodies, and distributes them along the resisting medium, through which it must force its passage. Upon this principle, the longest flashes of *lightning* seem to be made, by its forcing into its way part of the vapours in the air. One of the principal reasons why those flashes make so long a rumbling, is their being occasioned by the vast length of a vacuum, made by the passage of the electric matter. For although the air collapses the moment after it has passed, and the vibration, on which the sound depends, commences at the same moment; yet, if the flash was directed towards the person who hears the report, the vibrations excited at the nearer end of the track will reach his ear much sooner than those excited at the more remote end; and the sound will, without any repercussion or echo, continue till all the vibrations have successively reached him. Mr. Lullin, in order to account for the production of electricity in the clouds, made a long insulated pole to project from one side of the Alps, and observed, that when small clouds of vapour, raised by the heat of the sun, rose near the foot of the mountain, and ascended along the side of it; if they touched the extremity of the pole only, it was electrified; but if the whole pole, and consequently part of the hill on which it stood, was likewise involved, it was not electrified. Whence he concludes, that the electricity of the clouds is produced by their passing through the air while the sun shines upon them. But to which of these two circumstances, namely, the motion through the air, or the action of the sun's rays, this was owing, he could not determine, though he made several experiments for this purpose.

Upon the whole, it is easy to conceive, that when particular clouds or different parts of the earth possess oppositie electricities, some being electrified positively, and others negatively, a discharge will take place within a certain distance; or the one will strike into the other, and in the discharge a flash of *lightning* will be observed. But how the clouds or earth acquire this state, is still a question not absolutely determined. Mr. Canton queries, whether the clouds become possessed of electricity by the gradual hearing and cooling of the air; and whether air suddenly rarefied, may not give electric fire to, and air suddenly condensed receive electric fire from, clouds and vapours passing through it. Mr. Wilcke supposes the air to contract its electricity, in the same manner as sulphur and other substances do, when they are heated and cooled in contact with various bodies. Thus the air, being heated or cooled in the neighbourhood of the earth, gives electricity to the earth, or takes it from it, and the electrified air, being conveyed upwards by various means, communicates its electricity to the clouds. Others have queried, whether, since thunder generally happens in a sultry state of the air, when it seems replenished with some sulphureous vapours, that the electric matter then in the clouds may not be generated by the fermentation of sulphureous vapours with mineral or acid vapours in the air.

Dr. Franklin advises persons who are apprehensive of danger from *lightning*, to sit in the middle of a room, provided it be not under a metal lustre suspended by a chain, sitting on one chair, and laying their feet on another. It is still safer, he says, to bring two or three mattrasses, or beds into the middle of the room, and folding them double, to place the chairs upon them, for as they are not so good conductors as the walls, the *lightning* will not chuse to pass through them; but the safest place of all is in a hammock hung with silken cords, at an equal distance from all the sides of a room. Dr. Priestley observes, that the place of most absolute safety must be the cellar, and especially the middle of it; for when a person is lower than the surface of the earth, the *lightning* must strike it before it can possibly reach him. In the fields, the place of safety is within a few yards of a tree, but not quite near it. Nevertheless, S. Beccaria cautions persons not to depend upon the neighbourhood of a higher, or, in all cases, a better conductor than their own body; since, according to his repeated observations, the *lightning* by no means descends in one undivided track; but bodies of various kinds conduct their share of it at the same time, in proportion to their quantity and conducting power. See on the subject of this article Franklin's Letters; Beccaria's Lettre dell'

Electricismo; Priestley's History, &c. of Electricity, passim. Lord Mahon observes, that damage may be done by *lightning*, not only by the main stroke and lateral explosion, but likewise by that which he calls the returning stroke, that is, by the sudden violent return of that part of the natural share of electricity (of any conducting body, or of any combination of conducting bodies) which had been gradually expelled from such body or bodies respectively, by the superinduced elastic electrical pressure of a thunder cloud's electrical atmosphere. See an account of his theory and experiments, relating to this subject, in his Principles of Electricity, &c. quarto. 1779.

LIGHTNING, *artificial*. The phosphorus, when newly made, gives a sort of artificial *lightning* visible in the dark, which would surprise those who are not used to such a phenomenon: the usual method of keeping this preparation is under water, and if the coruscations are desired to be seen to the greatest advantage, the glass in which it is kept should be deep and cylindric, and not more than three-fourths filled with water. The phosphorus put into this water will send up coruscations at times, which will pierce through the incumbent water, and expand themselves with great brightness in the empty upper part of the bottle.

If we compare this artificial coruscation to the real *lightning*, we shall find, that as in this the fire passes unaltered through the water, so in that the flashes of *lightning*, which come at intervals, pass uninterrupted through the most dense clouds, and are not obstructed by the heaviest storms of rain, but like the beams of the sun, or any other fire, pass uninterrupted through glass and water. The season of the weather, as well as the newness of the phosphorus, must concur to produce these flashes; for they are as uncommon in winter as *lightning* is, but in warm weather both are very frequent.

The flame of *lightning* is generally inoffensive, and does not, except upon particular circumstances, set fire to any thing that it falls upon; and, in like manner, the flashings of the phosphorus through the water will not burn the flesh, nor even fire the most combustible things; though the phosphorus itself, like the *lightning*, under proper circumstances, may be a very consuming and terrible fire. The warmth of the air, or the immediate beams of the sun, will set fire to the condensed body of the phosphorus, and it then becomes this terrible fire; and in the same manner, *lightning* when condensed and contracted, and wrapped up in a vehicle of air, so that it does not so easily diffuse itself through the yielding ether, sets fire to trees, houses, or whatever it comes near.

The phosphorus, while burning, acts the part of a corrosive, and when it goes out resolves into a menstruum, which dissolves gold, iron, and other metals; and *lightning*, in the same manner, melts the same substances. From the whole, it appears that there is much more resemblance between this phosphorus and *lightning*, than between gunpowder or aurum fulminans, and that fire; though these have often been supposed to be nearly allied to its nature. See PHOSPHORUS.

LIGNEA *casse*. See CASSIA.

LIGNICENSIS *terra*, in the *Materia Medica*, the name of a fine yellow bole dug in many parts of Germany, particularly about Emerie, in the circle of Westphalia, and used in cordial and astringent compositions. It is a common succedaneum for the yellow Silesian bole, where that is not to be had, and is generally esteemed very nearly, if not absolutely equal to it in its virtues.

It is moderately heavy, naturally of a smooth surface, and of a beautiful gold colour. It easily breaks between the fingers, and does not stain the skin in handling, melts freely in the mouth, and leaves no grittiness between the teeth, and is immediately diffusible in water. It makes no effervescence with acids; and burns to a fine red colour, and almost to a stony hardness.

Charlton (Foss. p. 5.) says it is more frequently known by the name of *terra sigillata Goldbergensis*.

There is another white bole known by this name. See GOLTBERGENSIS *terra*.

LIGNITES, the name of a stone described by Ludovicus Dulcis, as having the veins and appearance of wood, and the transparence of glass. He celebrates it for many imaginary virtues, nor does the stone itself indeed seem much less imaginary; this author, as De Boot observes, having described many stones which he never saw, and no small number that never existed.

LIGNUM *aloes*, or *wood of aloes*. See ALOES.

LIGNUM *balsami*. See BALSAM.

LIGNUM *Campechianum*. See LOG-WOOD.

LIGNUM *casiæ*. See CASSIA.

LIGNUM *colubrinum*. Garcias tells us of the wonderful effects of this drug against the bites of venomous serpents, and describes two kinds of the plant which produces it; one having leaves like the pomegranate, and the other like the peach-tree: these, he says, both grow in the island of Ceylon; and Acosta mentions two other species of plants producing this wood, both different from either of those described by Garcias, and both growing in Malabar. We have also accounts in the Geographus Nubiensis of another *lignum colubrinum*, different from these, growing in Æthiopia, and possessed of the same virtues against the bites of serpents as the others. This last is called in the Arabic *hond albar*, the plain verbal translation of which is snake-wood, or *lignum colubrinum*. He tells us, that it has some resemblance in form to pyrethrum, and that the wood is always contorted.

Alba cavarba is another of its Arabic names, and this is the word by which Avicenna, and the other Arabian writers, interpret the *pyrethrum* of Dioscorides; but it is not certain, whether the similitude of sounds between two or more Arabic words, may not have occasioned some confusion or error here. Dicearchus, in his fragment of mount Pelion, describes the root of a tree growing there, which is not only a sovereign remedy for the bites of serpents, but even destroys them by its smell. This is also a *lignum colubrinum*; but whether the same with any of the others, or different from them all, we have not descriptions enough to determine.

It appears, upon the whole, that little can be depended on in the accounts of the medicine called *lignum colubrinum* by any author, unless he has himself experimented what he relates, and described the plant which produces the drug; for much imaginary virtue has been at all times given to many things against the bitings of serpents, and the *lignum colubrinum* of one author is not the *lignum colubrinum* of another.

LIGNUM *nephriticum*. See NEPHRITIC.

LIGNUM *vitæ*, the wood of a genus of trees, called by botanists *thuya*. See TREE *of life*.

Lignum vitæ is much valued by turners; making extremely beautiful cups, bowls, boxes, and other curiosities.

Lignum vitæ is also a name given to GUAIACUM.

LIGULA, a word used by medical writers in very different senses. Some express by it the clavicle, others the glottis; others use it as the name of a measure, for things either liquid or dry, being a quarter of a cyathus, equal to a forty-eighth part of a pint with us; others finally use it for a weight, less than half an ounce by two scruples, or ten scruples.

LIGULA *marina*, a name given by some botanical writers to a plant of the fucus or sea-wrack kind, called by others *fucus in ligulas divisus*. It usually grows in places always covered by the sea, not on the banks, which are dry at the ebbing of the tides; and is for the most part composed of a sort of long cords or strings. The stalk is solid, and not hollow, as in the *fucus vesiculosus*, or the stringy fucus of Mr. Ray; at least the stalk of this plant is full of a thick and tough viscous matter, like that found in the bladders, at the extremities of the branches of the common fucus, at the time when the seeds are ready to fall. This gluey matter is of a whitish green, and the colour of the plant itself is a deep olive; there is no rib or nerve to be seen in any part, but its texture is very close and compact.

The indefatigable Mr. Reaumur discovered irregular flowers in this plant; they are each composed of a number of short and slender filaments, issuing out of a little hole, which serve them as a cup. These filaments are disposed in a circular order upon the stalk; and resemble, in miniature, the common radiated flowers of the hawkweed, and the like plants; but their diameter is not more than the twentieth part of an inch. Notwithstanding the smallness of these flowers, they are however easily distinguished, because they are green; whereas the stalk is olive-coloured. Mem. Acad. Par. 1711.

LIGULATED *floscules*, *ligulati flosculi*, in *Botany*, a term used by authors to express a part of the floscules, or small separate flowers, which together form the whole head or flower of the compound flowered plants. The *ligulated floscules* generally stand on the edge, and have a flat straight end turned downwards, and armed with three teeth, but not divided into any segments.

LIGURINUS, in *Zoology*, a name used by many authors for the bird more commonly known by the name of SPINUS, and called in England the *siskin*.

LIGURIUS, in *Jewish Antiquity*, a precious stone on the high priest's breast-plate. It is called *leshem* in Hebrew. Theophrastus and Pliny describe the *ligurius* to be a stone like a carbuncle, of a brightness sparkling like fire.

The *ligurius* was the first stone in the third row upon the high priest's pectoral, and the name of God was inscribed upon it. Ælian, De Animal. lib. iv. cap. 17. Pliny, lib. viii. cap. 38. & lib. xxxvii. cap. 3. Calm. Dict. Bibl. See LYNCURIUS *lapis*.

LIGUSTICUM, or LEVISTICUM, in *Botany*. See LOVAGE.

LIGUSTICUM *marmor*, in *Natural Hiſtory*, a name by which ſome authors have called the *Carrara marble*, the *marmor lunenſe* of the ancients. It is a fine white marble, harder than the Parian or ſtatuary kind, and uſed for tables, chimneys, &c. as the other for carving. See LUNENSE *marmor*.

LIGUSTRUM, in *Botany*. See PRIVET.

LIKE *quantities*, in *Algebra*, are thoſe which are expreſſed by the ſame letters, under the ſame power, or equally repeated in each quantity.

Thus $2b$, and $3b$, and $9ff$, and $3ff$, are *like quantities*; but $2b$, and $3bb$, and $9ff$, and $3fff$, are unlike ones, becauſe the quantities have not every-where the ſame dimentions, nor are the letters equally repeated.

LIKE *ſigns*, or *ſymbols*, in *Algebra*, are when both are affirmative, or both negative.

If one be affirmative, and the other negative, they are unlike ſigns.

Thus $+6d$ and $+5d$, have *like* ſigns; but $+9f$ and $-7f$, have unlike ſigns.

LIKE *figure*, in *Geometry*, are ſuch as have their angles equal, and the ſides about thoſe equal angles proportional. See SIMILAR.

LIKE *arches*, in the projection of the ſphere in plano, are parts of leſſer circles, containing an equal number of degrees with the correſponding arches of greater ones.

LIKE *ſolid figures*, in *Geometry*, are ſuch as are contained under *like* planes, equal in number.

LILAC, *ſyringa*, in *Botany*, a genus of the *diandria monogynia* claſs. Its characters are theſe: the flower has a ſmall tubulous permanent empalement of one leaf, indented in four parts; it has one petal with a long cylindrical tube, cut into four obtuſe ſegments at the brim, which ſpread open, and two very ſhort ſtamina, terminated by ſmall ſummits, ſtanding within the tube; it has an oblong germen, ſupporting a ſhort, ſlender ſtyle, crowned by a thick, bifid ſtigma; the germen afterward turns to an oblong, compreſſed, acute-pointed capſule, with two cells, opening with two valves, contrary to the partition, including in each cell one oblong acute-pointed ſeed, with a membranaceous border. Linnæus reckons two ſpecies, and Miller three.

Theſe are frequently cultivated in gardens; and ſome growing, with good management, to eighteen or twenty feet high, are with their large tufts of flowers very ornamental.

The common way of propagating theſe ſhrubs is by ſuckers, which they always produce in very great abundance; theſe ſhould be taken off from the old plants in October, and carefully planted in a nurſery, in rows three feet aſunder, and one foot diſtant in the rows, where after they have ſtood a year or two to get ſtrength, they will be fit to plant in autumn, where they are to remain; after which they require no farther care than the digging about their roots once a year, and taking away their ſuckers, which are not only very unſightly, but ſtarve the plant. Miller. They will grow almoſt any where; but they are obſerved to flower beſt in a light, rich ſoil, as indeed do moſt other ſhrubs, though they grow faſteſt in a wet one.

LILI, the name of one of the favourite remedies of Paracelſus, the baſis of which is antimony; but he has not given us the proceſs for preparing it.

LILIAGO, in *Botany*, a name uſed by Cordus and ſome other authors for the phalangium or SPIDERWORT.

LILIACEOUS, in *Botany*, a term uſed to expreſs the flowers of ſome plants, which approach to thoſe of the lily in ſhape.

The characters of a *lilaceous* flower are theſe: it is compoſed of ſix leaves, or elſe of three leaves divided into ſix; but this is more rarely the caſe; the piſtil, or cup of this flower, always becomes finally a ſeed-veſſel divided into three cells.

Of this ſort are the flowers of the tulip, hyacinth, aſphodel, ephemerum, and the like; many of which, though they leſs reſemble the lily flowers than the others, yet are to be diſtinguiſhed by this title, becauſe they leave behind them the *lilaceous* ſeed-veſſel, which is long, and divided into three cells. Tourn. Inſt. p. 343. See *Tab.* IX. *of Botany, Claſs* 9.

LILIASTRUM, in *Botany*. See *Aſphodel* LILY.

LILIO *aſphodelo*. See *Aſphodel* LILY.

LILIO *fritillaria*. See FRITILLARY.

LILIO *hyacinthus*. See SQUILL.

LILIO *narciſſus*. See AMARYLLIS.

LILIUM *lapidarum*, a name given by the writers, in *Natural Hiſtory*, to a foſſile body found in ſome parts of Germany; which plainly ſhews, that it was once a ſpecies of ſtar-fiſh; though the animal be not, at this time, known in its recent ſtate. Klein, who has well conſidered this body, in compliance to the vulgarly received names of things, calls this the *entrochus ramoſus*, or *branched entrochus*; and the reſemblance ſome of its parts have to the common entrochi, ſhews plainly, that their origin has been the ſame, and that they are fragments either of this ſpecies or of the Magellanic ſtar-fiſh. The recent fiſh not being found from which the *lilium lapidarum* is formed is no peculiar fate, but is common to it, and to the *cornua Ammonis*, and many other animal remains.

LILLO, in *Ichthyology*, a name given by the Rhodians to the LABRUS.

LILLY *of Paracelſus*. See TINCTURE *of metals*.

LILY, *lilium*, in *Botany*, a genus of the *hexandria monogynia* claſs. Its characters are theſe: the flower, which is of the open bell-ſhape, has no empalement, but has ſix petals reflexed at their points; each petal having a narrow longitudinal nectarium at its baſe: it has ſix erect ſtamina with a cylindrical oblong germen, which afterward becomes an oblong capſule, with ſix rough furrows hollowed at the top, having three cells filled with flat ſeeds lying above each other in a double order. Miller enumerates thirteen and Linnæus nine ſpecies.

All the ſorts of *lilies* may be propagated by off-ſets from their roots; or by ſowing their ſeeds; and if the ſeeds are carefully ſaved from good flowers, the mariagons very frequently afford very beautiful varieties.

The manner of ſowing them is this: ſome ſquare boxes ſhould be provided of about ſix inches deep, with holes bored in the bottoms to let out the wet; theſe muſt be filled with freſh light ſandy earth, and the ſeeds muſt be ſown on them pretty thick in the beginning of October, ſoon after they are ripe, and covered over about half an inch deep with light ſifted earth of the ſame kind. They ſhould be then placed where they may have the morning ſun; and, if the weather prove dry, they muſt be watered at times, and the weeds carefully picked out. In the beginning of November, the boxes are to be removed to a place where they may have as much ſun as poſſible, and be ſecured from the north and eaſt winds. In ſpring about the beginning of April, the young plants will appear, and the boxes are then to be removed into their former ſituation; they ſhould be watered at times during the ſummer; and in Auguſt the ſmalleſt roots are to be emptied out of theſe boxes, and ſtrewed over a bed of light earth, and covered with about half an inch depth of light earth ſifted over them; they muſt here be watered and ſhaded at times, and defended from the ſeverity of the winter, by a light covering of ſtraw, or peas haulm, in the hardeſt weather. In February the ſurface of the bed ſhould be cleared, and a little light earth ſifted over it. When the leaves are decayed, the earth ſhould be a little ſtirred over the roots, and in the month of September following a little more light earth ſifted on. In the September, of the following year, the roots muſt be tranſplanted to the places where they are to remain, and ſet at eight inches diſtance, the roots with their buds uppermoſt, being placed four inches below the ſurface: this ſhould be done in moiſt weather. They will now require the ſame care as in the preceding winters; and the ſecond after they are tranſplanted, the ſtrongeſt roots will begin to flower. The fine ones ſhould then be removed at the proper ſeaſon into flower-beds, and planted at great diſtances from one another, that they may flower ſtrong.

The roots of the *white lily* are emollient, maturating, and greatly ſuppurative. They are uſed externally in cataplaſms for theſe purpoſes with ſucceſs. The common form of applying them is boiled and bruiſed; but ſome prefer the roaſting them till tender, and then beating them to a paſte with oil, in which form they are ſaid to be excellent againſt burns. Gerard recommends them internally in atrophies.

For this purpoſe, bread was made of barley-meal, with the juice of the roots, and conſtantly uſed for a month or ſix weeks; but Dr. Lewis obſerves, that there are inſtances of ſimilar cures by the uſe of common bread; and that probably in one caſe, as well as in the other, abſtinence from liquids was the remedy. The flowers are chiefly uſed for ſtavouring expreſſed oils, which, by infolation with freſh parcels of them, continued about three days each time, are ſuppoſed to receive from them, along with their ſmell, an anodyne and nervine virtue. The diſtilled water has been ſometimes uſed as a coſmetic.

LILY, *belladonna*, *daffodil*, *Guernſey*, *Mexican*, and *Japan*, names uſed by different authors for the AMARYLLIS, or *lilio Narciſſus* of Linnæus and Tournefort.

LILY, *aſphodel*, *crinum*, in *Botany*, a genus of the *hexandria monogynia* claſs. Its characters are theſe: the flower has one petal, funnel-ſhaped, deeply cut at the top into ſix parts, which are reflexed; and has ſix long ſtamina, which are inſerted in the tube of the petal, ſpreading open; the germen is ſituated at the bottom of the flower, which afterward becomes an oval capſule with three cells, each

each containing one oval seed; the flowers are included in a two-leaved spatha. There are four species. See *Tab.* IX. of *Bot. Class* 6.

LILY, *daffodil*. See DAFFODIL.

LILY, *day*, or *St. Bruno's lily*, *hemerocallis*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the flower has no empalement; in some species the flower is of one petal, cut into six parts, in others it has six petals; there are six awl-shaped declining stamina surrounding the style: the roundish furrowed germen is situated in the middle, and becomes an oval three-cornered capsule, with three lobes opening with two valves, filled with roundish seeds. Miller reckons four, and Linnæus two species.

LILY, *hyacinth*. See SQUILLS.

LILY, *Mexican*. See LILY *of the valley*, infra.

LILY, *Persian*. See FRITILLARY.

LILY, *superb*, *gloriosa*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the flower has no empalement, but has six spear-shaped petals, which are waved and reflexed to the bottom; it has six stamina, which spread each way, terminated by prostrate summits; in the centre is situated a globular germen, which becomes an oval thin capsule with three cells, filled with globular seeds disposed in a double range. There are two species, natives of the East.

LILY-*thorn*. See *Lily*-THORN.

LILY *of the valley*, *convallaria*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the flower has one petal, which is bell-shaped, spread open and reflexed, but has no empalement; it has six stamina inserted into the petal; in the centre is situated a globular germen, which becomes a globular berry with three cells, containing one roundish seed. Miller enumerates ten and Linnæus eight species.

The plant commonly called *one blade*, and by Caspar Bauhine *folium convallium minus*, is usually esteemed a species of this genus, but improperly; it being one of the smilaxes. Tourn. Inst. p. 77. See SMILAX.

The name *lily* is very improperly given to this genus of plants, as they have not the least affinity to the *lily*.

The flowers of the white *lily of the valley* are cephalic and nervine, and prescribed for vertigoes, apoplexies, palsies, &c.

It is principally from the volatile parts of these flowers, that medicinal virtues have been expected in nervous and catarrhous disorders; but probably their fixed parts also have no small, perhaps the greatest, share in their efficacy: the flowers, dried and powdered, and thus divested of their odoriferous principles, prove strongly sternutatory. Watery or spirituous extracts made from them, given in doses of a scruple or half a dram, act as gentle stimulating aperients and laxatives; and seem to partake of the purgative virtues, as well as of the bitterness of aloes. Lewis's Mat. Med.

LILY, *water*, *nymphæa*, in *Botany*, a genus of the *polyandria monogynia* class. Its characters are these: the empalement of the flower is composed of four or five coloured leaves; the flower has many petals sitting on the side of the germen, for the most part in a single series; and it has a great number of short plain incurved stamina, with oblong summits; it has a large oval germen, but no style; with an orbicular, plain, target-shaped stigma; the germen becomes a hard, oval, fleshy fruit with a narrow neck, crowned at the top; and divided into ten or fifteen cells, full of pulp, with many roundish seeds. There are two species, which grow naturally in standing waters; Linnæus reckons four.

The best method to propagate these plants is to procure some of the seed-vessels just as they are ripe and ready to open; these should be thrown into canals or large ditches of standing water, where they will sink to the bottom, and in the following spring the plants will appear floating on the surface of the water, and in June or July produce their beautiful large flowers: when they are once fixed to a place, they will multiply exceedingly; in small gardens they are cultivated in large troughs of water lined with lead, where they thrive very well; but few persons care to be at that charge. Miller.

The roots, flowers, and sometimes the leaves, have been employed both internally and externally, as demulcent, anti-inflammatory, and in some degree anodyne: they are cooling and drying, and accounted good to stay all kinds of fluxes and lasciviousness, and the gonorrhœa and nocturnal emissions; by their softening cooling qualities allaying the acrimony of the semen, and thereby rendering persons less disposed to venery. The leaves are good to be applied to hot humours and inflammations.

LILY, *water yellow*, *water*. See *Nup*-BEAN.

LIMANDA, in *Ichthyology*, a name by which some authors have called the flat-fish, which we in English call the DAB, the *pesce liscio* of authors.

LIMARIA, in *Ichthyology*, a name given by Gaza and some other writers to the THYNNUS or TUNNY-*fish*, called the *Spanish mackrel*.

LIMATURA *mortis præparata*. See IRON.

LIMAX, in the *History of Insects*, the name of a genus of these animals, comprehending all the naked snails. See SNAIL.

This belongs to the order of mollusca or soft worms in the Linnæan system. The animals of this genus have no shell, and are furnished with members.

The body of the *limax* is of an oblong figure, approaching to cylindric, and is perforated at the side with a hole, which serves for its genitals and discharge of excrements; above is a fleshy kind of buckler, formed convexly and flat beneath; the tentacula are four in number, and two of them have the appearance of eyes.

Of this genus authors enumerated eight species.

LIMAX *marinus*, in *Zoology*, a name given by some to the *lepparis*, or, as it is commonly termed in English, the *sea-fowl*, caught in plenty at the mouths of rivers in Yorkshire, and some other places. See CYLINDRUS.

LIMB, in *Anatomy*, is used to denote certain parts of the human body, proceeding from the trunk.

LIMBS, *motions of the*. By a sort of natural mechanism, and that without any acquired habitude, we are capable of easily making with one hand, or even with both hands at once, exactly the counter action to that motion, which the other hand naturally and most easily is found to make, and the contrary of which it cannot itself make without difficulty, and repeated trials and custom. It is owing to this, that we can with the left hand easily make the very contrary strokes with the pen, that we are accustomed to make with the right; if we suffer that left hand to move, without giving our particular attention to what it is doing, as in the playing on some instruments of music, the fingers being after practice left, as it were, to themselves, succeed more happily than when the attention is more engaged in what they are doing. The letters or figures thus made by counter strokes from the unforced action of the left hand, though they appear strange and confused at first sight, yet if held up against a looking-glass, they will be found sufficiently determinate and expressive.

This difficulty of making motions, at the same time, contrary to one another with two *limbs*, either of which motions singly would be no difficulty to either, is not peculiar to the arms; if we sit down and try the experiment with the feet, the success is found the same, and even the moving differently the like fingers or toes of the different hands or feet, is found of proportionate difficulty.

We, in the same manner, are not able, by any means, to direct our two eyes to two different objects, placed in contrary situations at the same time; but in this the difficulty, though great in the structure of our eyes, is not universal to all creatures. The chamæleon being able to do this, and to look before and behind, or in any other two different directions, both at the same time. Mr. Winslow was led by a great number of observations of this kind, diligently to examine the dispositions of the nerves, and their different origins in the brain, the cerebellum, the medulla oblongata, and the spinal marrow. The first thing on which this accurate anatomist made his observation, was the crucial interlacement of the nerves in the medulla oblongata, first discovered by M. Petit, and accurately described and figured by him; and the observations of the same author, of different persons, who, within his own knowledge, had become paralytic in the *limbs* on the contrary side of their body to the affected part of the brain also. The being able determinately to bring on the like symptoms in brutes, from injuries to the contrary sides of the brain, and the regular evolling of the filaments which pass transversely on the medullary arch, commonly called the callous body of the brain, and of other of the nervous fibres, seemed to promise to give some light into the explication of the difficulty of these contrary motions being performed at the same time. When this accurate observer had sufficiently informed himself of these crossings of the nerves, and the other reciprocal communications of the several parts of the brain, or its two lateral halves, as well as by the two large transverse cords, as by the thick transverse fibres of the small inferior and triangular surface of the arch, he bestowed his particular observation on the structure of the spinal marrow. This he carefully examined by the microscope; and beside the transverse fibres, which make the communication between the two columns of this marrow, and which M. Petit had before nicely described, there appeared to M. Winslow, in the thickness of each of these columns, a long train very distinct, and made up of a less white and more cloudy matter than the rest; or a medullary cord, which had not been before observed

observed by any body, any more than the fmall cords and tranſverſe fibres of the ſummit of the arch of the brain, or the croſſing of its tranſverſe fibres.

By theſe ſeveral croſſings, and reciprocal communications of the medullary filaments, which are, as it were, the roots of the nerves of each half, or each ſeveral ſide of the human body, it ſeems not impoſſible to explain the reaſon of the before obſerved difficulty of making the contrary motions with the two oppoſite *limbs* at the ſame time; eſpecially when it is obſerved, that the two ſmall parcels of medullary filaments, which compoſe the primitive trunks of every pair of nerves that are propagated from the ſpinal marrow, have their paſſage through the lateral apertures of the vertebræ, and before that ſeem to proceed partly from the neighbouring column or moiety of the ſpinal marrow, and partly from the other column or moiety, by means of the croſſing before mentioned; and conſequently, that by this reciprocal croſſing, or interlacing, one of the primitive parcels or bundles of filaments of each primitive trunk of the nerves of one ſide of the body, muſt communicate with the fellow-parcel or bundle of filaments of the nerves of the other ſide.

Every body almoſt knows that the motion of the muſcles, and ſenſation by the touch, are performed by means of the nerves and their filaments; but no one has ever yet diſcovered the true means: this however is certain, that when we would put to motion, at one time, the two legs, or the two arms, or the fingers or toes of each hand or foot, at that time the croſſed filaments of the primitive trunks of the nerves, which go to their correſpondent muſcles on each ſide, immediately come mutually into contact and conſent with one another; and their ſo meeting, in the time of their motion, communicates certain impreſſions reciprocally to the ſeveral nerves, which from them are propagated to the two different ſides of the body, and continue them to act in concert on the ſeveral muſcles of both the arms or legs at the ſame time, and communicate to both that principle of motion, which we meant to give alone to one. Mem. Acad. Scien. Par. 1739.

The *limbs*, as well as the life of a man, are of ſuch high value, in the eſtimation of the law of England, that it pardons even HOMICIDE, if committed *ſe defendendo*, or in order to preſerve them.

LIMB, LIMBUS, the outermoſt border, or graduated edge, of an aſtrolabe, quadrant, or the like mathematical inſtrument.

The word is alſo uſed for the primitive circle in any projection of the ſphere in plano.

LIMB alſo ſignifies the outermoſt border or edge of the ſun or moon, when the middle or diſk is hid in an eclipſe of other luminary.

Aſtronomers obſerve the lower and the upper *limb* of the ſun in order to find its true height, which is that of the centre.

LIMB is alſo uſed, among *Botaniſts*, for the outer edge or border of plants, their leaves and flowers. See PETAL.

LIMBECK. See ALEMBIC.

LIMBERS, in *Artillery*, a pair of advanced train joined to the carriage of a cannon, upon a march. It is compoſed of two ſhafts, wide enough to receive a horſe betwixt them, which is called the *fillet horſe*: theſe ſhafts are joined by two bars of wood, and a bolt of iron at one end, and have a pair of ſmall wheels; upon the axle-tree reſts a ſtrong iron ſpike, upon which the train of the carriage is put. But when a gun is upon action, the *limbers* are run out behind it.

See the dimenſions and figure of a *limber* carriage, in Muller's Treatiſe of Artillery, p. 187, &c.

LIMBER-*holes*, in a ſhip, little ſquare holes cut through her floor-timbers, ſerving to let the water to the well of the pump, which otherwiſe would lie between thoſe timbers, where the keel rope runs.

Every floor-timber has two *limber* holes cut through it; viz. one on each ſide of the keelſon.

LIMBER-*boards*, are ſhort pieces of plank, which form a part of the ceiling or lining of a ſhip's floor, cloſe to the keelſon, and immediately above the *limber-s*. They are occaſionally removed, in order to examine and clear the *limber*-holes.

LIMBER-*rope*, is a long rope, frequently retained in the *limber*-holes of a ſhip, and communicating from one to another, in order to clear them, by pulling the rope backwards and forwards, ſo as to ſoften the ſand or dirt by which they may occaſionally be choaked.

LIMBUS, or LIMB, is a term in the *Roman Theology*, uſed for that place where the patriarchs are ſuppoſed to have waited for the redemption of mankind, and where they imagine our Saviour continued from the time of his death to that of his reſurrection.

Du-Cange ſays, the fathers calls this place *limbus, ex quod ſit limitis confervatio*, as being the margin or frontier of the other world.

LIMBUS is alſo uſed by catholics for the place deſtined to receive the ſouls of infants, who die without baptiſm; who have not deſerved hell, as dying in innocence; nor yet are worthy of heaven, becauſe of the imputation of original ſin.

LIME, *ſalt of ſtone*, a white, ſoft, friable ſubſtance, prepared of ſtone, marble, chalk, or ſome other ſtony ſubſtance, by burning in a KILN.

The great uſe of *lime* is in the compoſition of mortar for building; the fire taking away a great part of its humidity, and opening its pores, ſo that it becomes eaſily reducible to powder, and miſcible with ſand or burnt clay. See MORTAR.

LIME, *quick*, or *caſtic lime*, is ſuch as it comes out of the kiln, or furnace. And thoſe earths or ſtones, which yield this acrimonious, friable ſubſtance, are called CALCAREOUS or calcinable. The method of converting earths and ſtones into *quick-lime* is very ſimple: it conſiſts in expoſing them to the action of fire, in kilns made for this purpoſe, till they become of a white-red heat, and in keeping them in this degree of heat during twelve or fifteen hours: good *quick-lime* may alſo be made with a leſs heat continued for a longer time, or in leſs time with a more intenſe heat; but care muſt be taken that the heat is not ſufficiently violent to vitrify the calcareous ſtone. The effects of CALCINATION, and the principal properties that diſtinguiſh *quick-lime* from uncalcined calcareous earths, are the following: the earths and ſtones, from which *quick-lime* is produced, contain a large quantity of air in a fixed ſtate, called *fixed* AIR, and by ſome writers calcareous gas, which, in calcination, is expelled; and therefore, in this proceſs, they are rendered more friable, and their weight is very conſiderably diminiſhed. See HEAT *Potential*.

Mr. Jacquin, in his Examen Doctrinæ Meyerianæ, (ſee ACTUUM *Pinyon*) obſerves that *lime-ſtone* contains ⅓ of its weight of gas, and ⅓ of water. In conſequence of this diſcharge of air, ſtrong *quick-lime*, though diſſoluble in all the acids, with conſiderable heat, raiſes no effervescence, or emits no air-bubbles, which the uncalcined earths do in great abundance. Moreover, if the calcined ſtones be left expoſed to the air, they crumble into a fine white powder, called *lime ſlaked in the air*, and recover great part of their original weight. If the *quick-lime*, while newly made and very ſtrong, be put into water, inſtead of expoſing it to the air, it preſently cracks and ſplits with noiſe, exhaling a hot watery vapour, and ſoon crumbling to as fine a powder as if it had been a long time expoſed to the air. But the crude *lime*-ſtone, before its calcination, exhibits none of theſe phenomena, with air or with water. *Lime*-water not decompoſed, which is nothing elſe but water ſaturated with *quick-lime*, produces the ſame appearances with acids and other ſubſtances as the *quick-lime* itſelf, excepting that its combination with theſe ſubſtances is not accompanied with ſo much heat. *Quick-lime* and *lime*-water have not only the acrimonious taſte, but alſo all the other properties of fixed alkalis. Thus *quick-lime* changes the blue colours of flowers to a green, precipitates all metallic ſolutions, and even ſome ſalts with earthy baſes, ſuch as alum, and decompoſes ammoniacal ſalts, from which it diſengages the volatile alkali. It has ſome action upon oils, ſpirit of wine, and eſpecially upon ſulphur, which it reduces to an hepar. Theſe alkaline ſaline properties diſtinguiſh *quick-lime* from uncalcined calcareous earths, which, however, in a ſmall degree poſſeſs ſome of the ſame properties. The theory of *quick-lime* has been very much improved by the modern diſcoveries relating to *fixed* AIR. We learn from the experiments of Hales, Black, Jacquin, and others, that if calcareous ſtones are calcined in an apparatus of cloſe veſſels, ſo that whatever is expelled by fire may be retained, they may be converted into *quick-lime*, without the concurrence of the external air; that, during this calcination, a certain quantity of aqueous liquor is expelled from calcareous ſtones, though they have been previouſly well dried, and moreover, that a conſiderable quantity of a volatile vapour is diſengaged during the calcination, and that this vapour is the ſame as the gas or fixed air, which is expelled by adding acids to calcareous earth, and which occaſions the effervescence that ariſes upon mixing theſe ſubſtances. From this diſcovery of the exiſtence of gas in calcareous earths, and of the total privation of this fluid in *quick-lime*, we obtain a clear and ſatisfactory explication of the various properties of *quick-lime* and alſo of other ſimilar ſubſtances. Dr. Black has taught us, that *lime*-ſtone and other calcareous earths become *quick-lime*, when they are deprived by calcination in fire, ſolution in acids, precipitation with ſubſtances void of air, of the gas or air uſually combined with them in their natural ſtate. His experiments likewiſe prove, that when alkalis, fixed or volatile, are deprived of their gas, by any means, and

particularly by combination with *quick-lime*, they are thereby rendered more caustic, incapable of effervescing with acids, and of crystallization, and more powerfully solvent; and the *quick-lime*, &c. by thus communicating causticity to alkalies, loses its own causticity, and acquires all the properties of uncalcined calcareous earth: and he has shewn more generally, that by recombining this gas with *quick-lime*, magnesia, or alkalies, which had been previously deprived of it, their former weight and properties are destroyed. From the greater acrimony communicated to *quick-lime* and to alkalies, by thus depriving them of their contained gas, he has distinguished them, when thus deprived, or uncombined with gas, by the epithet caustic, as caustic calcareous earth, or caustic fixed alkali, or caustic volatile alkali; and when these earths or alkalis are combined with gas, he calls them mild. See ALKALI.

Dr. Black contrived an apparatus by which the gas extricated from an effervescing mixture, could be conveyed into a caustic alkaline liquor, and shewed that by this method the caustic alkali could be rendered mild, and recover its effervescing and crystallizing properties.

His apparatus consisted of two phials communicating by means of a bent tube, one end of which is inserted into the mouth of one phial, and the other end into the mouth of the other phial. In one of the phials he put some caustic spirit of sal ammoniac, and into the other phial some mild alkali or mild calcareous earth. Upon this mild alkali or mild calcareous earth, he poured through a hole made in the side of the phial, some acid liquor, which immediately produced an effervescence as usual, that is, it carricated from the alkali or earth their contained gas. The gas thus disengaged, passed through the bent tube into the phial containing the spirit of sal ammoniac, with which it combined, and which it changed from a caustic into a mild state. For the spirit is, by this process, rendered capable of effervescing with acids, and if it be much concentrated, it will be seen to crystallize during its impregnation with gas.

Dr. Macbride employed a similar apparatus to impregnate *lime*-water with gas, by which means he changed the caustic earth or *quick-lime*, which was dissolved in the water, to a mild calcareous earth, which, not being soluble in water, as *quick-lime* is, was therefore precipitated: he has also shewn, that this gas is capable of being absorbed by water, and that the water thus impregnated, precipitates the *lime* from *lime*-water. See some other properties of this gas recited under the article *fixed* AIR.

Dr. Black has farther determined, by experiments, the relative powers of the several alkaline substances to unite with this elastic fluid, or the AFFINITIES of this fluid towards these substances. He found that this gas was more disposed to unite with caustic calcareous earth or *quick-lime* than with any other substance; next with fixed alkali; then with magnesia; and lastly with volatile alkali. Whence he shews, that mild volatile alkali may be deprived of its gas or rendered caustic by applying to it magnesia deprived of its gas, or caustic fixed alkali, or *quick-lime*; and at the same time the magnesia, fixed alkali, or *quick-lime*, are thereby rendered mild. Magnesia also may be deprived of its gas by means of caustic fixed alkali, or of *quick-lime*; and lastly, mild fixed alkali may be rendered caustic by means of *quick-lime*, which is at the same time rendered mild. Hence soap-boilers in order to increase the activity or dissolving power of their alkali, boil it in water with *quick-lime*. According to this doctrine fully established by many experiments, the causticity and other peculiar properties of *quick-lime* and caustic alkali are the original properties of these substances, while they are pure and uncombined, and not communicated to them by any supposed absorption of matter from the fire in calcination, as Meyer and other chemists maintain. See ACIDUM *Pingue*.

From the now well-known property of fixed air in correcting air which has been injured by animal respiration or putrefaction, Dr. Priestley is led to conjecture, that *lime-kilns*, which discharge great quantities of fixed air, may be wholesome in the neighbourhood of populous cities, the atmosphere of which abounds with putrid effluvia. See on the subject of this article, Edinburgh Essays, vol. ii. Macbride's Essays, eff. v. and Chemical Dict. art. *Quick-lime*, and Appendix, ed. 2d.

LIME, *slaked*, is that diluted or drenched in water, and received for the making of mortar.

The best *lime* is that made of the hardest, firmest, and whitest stones; and which is slaked at its coming out of the furnace.

It may easily be determined whether a stone will calcine, by letting fall a few drops of aqua fortis, or any strong acid, on the stone, which will boil, and dissolve a part of it, if the stone is calcinable; but will lie upon the stone, like oil, and not ferment, if it will not calcine.

Sir H. Wotton looks on it as a great error in the English, to make *lime*, as they do, of refuse and stuff, without any choice; whereas the Italians, at this day, and much more the ancients, burnt their firmest stones, and even fragments of marble, where it was plentiful; which, in time, became almost marble again for its hardness, as appears in their standing theatres, &c.

We have two kinds of *lime* in common use in England; the one made of hard stone, the other of a soft, calcareous, or chalky stone; whereof the former is much the strongest. That made of soft stone, or chalk, is fittest for plastering of ceiling, and walls within doors; and that made of hard stones for buildings, and for plastering without doors.

Good *lime* may also be made of mill-stone, not coarse and sandy, but fine and greasy; as also of all kinds of flints; though it is hard to burn them, unless in a reverberatory furnace, as being apt to run to glass.

Dicuillant recommends *lime* made of sea-shells as the best; but Goldman finds fault with it, as being impatient of moisture, and therefore easily peeling off from the outsides of walls: it is, however, the common *lime* used in the Indies.

Before the stones be thrown into the kiln, they are to be broken to pieces; otherwise the air contained in their cavities, too much expanded by the heat, makes them fly with so much violence, as to damage the kiln. According to Alberti and Palladio, *lime* will not be sufficiently burnt in less than sixty hours intense heat.

The marks of a well-burnt *lime*, according to Alberti, are, that its weight be to that of the stone in a sesquialterate proportion; that it be white, light, and sonorous; that when slaked, it flicks to the sides of the vessels; to which Boeckler adds, that, when slaked, it sends forth a copious thick smoke; and Dicuillant, that it need a great deal of water to slake it. To preserve *lime* several years, slake, and work it up; dig a pit under ground, into which let it pass through a hole open at the bottom of the vessel. As soon as the pit is full, cover it up with sand, to prevent its drying; thus keeping it moist till it be used. Boeckler gives another method: cover a stratum of *lime* two or three feet high with another of sand of the like height; pour on water enough to slake the *lime*, but not to reduce it to dust after slaking. If the sand cleave into chinks, as the smoke ascends, cover them up, so as no vent may be given thereto. This *lime*, he adds, kept ten or twelve years, will be like glue; and will, farther, be of particular use in painting on walls, as being no way prejudicial to the colours. See MORTAR.

Lime is much used by tanners, skinners, &c. In the preparation of their leather; by soap-boilers for dissolving the oil, and facilitating its union with the alkaline salt; and by sugar-bakers for refining their sugar.

It is also of some medicinal use; being applied externally in deficative and epulotic medicines.

It is also used as a depilatory; and has been sometimes made into an unguent with honey for rheumatic and other obstinate fixed pains of the joints or limbs: this unguent is much commended by Fuller, who observes, that it is almost caustic. As an absorbent earth, it is anti-acid, and capable of absorbing the acid matters which are produced in digestion from the weakness of the stomach, in diseases proceeding from a spontaneous acid, so well described by Boerhaave. It is the fittest in these diseases, which are commonly the effect of the inactivity and weakness of the fibres, as it possesses a tonic quality, which other absorbent earths have not. Besides, persons afflicted with these diseases are subject to much wind, which is perhaps nothing else but gas; and *quick-lime* is very capable of absorbing that fluid. As *quick-lime* is also drying, a little caustic, and consequently cicatrising, it may contribute to cure certain ulcers, especially those of the soft parts. Accordingly, several able physicians have prescribed it successfully for internal suppurations, and in the phthisis pulmonalis. Moreover, the property which *quick-lime* has of attenuating viscid matters, and of decomposing ammoniacal salts, has been advantageously applied to dissolve stones in the bladder and kidneys. But the best method of administering *quick-lime* internally has been thought to be by giving the LIME-*water*; because this water is supposed to possess all the medicinal virtues of *quick-lime*, and because the earthy particles are thus reduced to the greatest fineness, and are consequently susceptible of the most perfect distribution. However, this should be administered with great caution, and much diluted; and, after all, it is doubted, whether the *lime-water*, thus diluted, has all the medicinal qualities which might be expected from *quick-lime*. MACQUER.

Lime affords a great variety of figures in its salts. The most perfect concretions among them seem to be double pointed figures, thick toward one end and growing slim toward the other; some are flat and of a quadrilateral figure,

figure, and others flat and very thin but hexangular; some are of the shape of a wedge, being cut off taper near one end, and blunt at the other. *Soda*, or pot-ash, made of the plant *kali*, is very elegant and various in its shoots. Some are beautiful prisms, with the angles cut off near each end; others are oblong, and less regularly formed, some square and very thin; others oblong, with a tendency to a rhomboidal shape, and some roundish. These are a few, out of a great number of experiments, made by the accurate Lewenhoeck, and since repeated by other observers. The salt, with the figures of these shoots, are published at large in the Philosophical Tranfactions. *Lime* makes the greatest improvement upon light sandy lands, or upon a dry gravel: but a cold clay seldom is much benefited by it. If it be mixed with dung, or with mud, drawn from the bottom of the rivers, it makes an excellent mixture, especially where the soil is very sandy; and in Westmoreland they procure fine crops of barley from their sandy lands, by manuring them with *lime* and cow-dung mixed together. The nature of *lime* on land is like that of chalk, it works downwards, as the farmers express it; it is therefore best to treat it in the same manner, laying it upon a lay the year before it is to be plowed up. *Lime* is reckoned to make corn grow with a thin husk; but it is not a lasting manure, seldom holding for more than five crops. When *lime* is used to land, which lies upon a descent, it should be mixed with dung, and laid principally on the higher part of the land; the consequence of which, will be, that the rain will wash out the virtue of the *lime* and dung together, and carry the whole to the lower parts as it runs down. Dung and *lime* mixed together will do better for any land than either of them alone.

All *lime* is a very good manure, but that made of stone is much better than what is made of chalk. The common allowance is a bushel to a pole square, or a hundred and fifty bushels to an acre.

This they cover with earth, and so leave it till the rains fall and slake it, and after this they spread it as evenly as possible upon the ground. They always find that if it be carried hot out of the kiln, and laid upon the land to cool, it does much better than in any other way.

The improvement it makes upon land is owing chiefly to its heat, and the salt it contains. It is in much the same manner that coal-ashes, and the soot of coal become useful upon the like sort of lands; but the farmers always find that a mixture of good earth and *lime*, that has lain a considerable time together, is better for this purpose than fresh *lime* alone. Moreton's Northampt. p. 481.

LIME, *bird*. See BIRD-*lime*.

LIME, *cream of*. See CREAM.

LIME-*galls*, in *Natural Hiſtory*, a ſort of *galls* or vegetable protuberances, formed on the edges of the leaves of the *lime*-tree in ſpring-time; they are very common in the plantations of *lime*, and are irregularly ſhaped, but uſually oblong and rugged, and of a reddiſh colour, they occupy only the edges of the leaves, and are of a red colour, ſometimes very beautiful. As theſe are very plentiful, Mr. Beaumur was of opinion, that they might be of ſervice in the dying trade; he made trial by rubbing them on ſome parts of his linen, and found that they gave a very beautiful red colour, which did not come out in the firſt waſhings afterwards. It is extremely probable, that there wants only inquiry to prove that we have many valuable productions of this kind, which, though diſregarded at preſent, might prove of great uſe in the ſeveral mechanical arts as well as in medicine.

Theſe *galls* of the *lime* leaves are formed by a worm, which inhabits them during its term of life, being found in them of *all ſizes*, from the moſt minute to that of the full growth, which is about half an inch in length; but when its period of life, as a worm, draws near, it deſerts this habitation, and goes elſewhere to paſs into its chryſalis ſtate. This alſo is the caſe with the worms that inhabit many *galls*, which are frequently found to contain them in the worm ſtate, but never in that of the chryſalis, which they always paſs into elſewhere.

Beſides theſe *galls* of the leaves of the *lime*-tree, they have ſometimes another appearance not leſs ſingular, and this is alſo owing to an inſect; though many curious obſervers have miſſed the finding it there. In this ſtate the whole leaf of the *lime*-tree reſembles a common ſpoon, being ſunk into a hollow in the middle, and in its pedicle making the handle. The edge of the leaf in this caſe is always turned, and forms a rib or ridge, running round the whole circumference in the ſhape of a cord: this is uſually found during the time that the leaf is growing to its ſize, and to this is owing the whole figure it aſſumes afterward; for the leaf being unable to extend itſelf farther toward the circumference by reaſon of this ring, naturally forms a ſort of hollow or baſon in its ſucceeding growth. The protuberance, in this caſe, ſurrounding the leaf is a kind of *gall*, and owes its origin in the manner of all the other excreſcences of that kind to an inſect. This, however, has been ſought for in vain by many, who inquired after it too late; but Mr Beaumur ſearching the leaves in the beginning of May, found in every protuberance of this kind, ſeveral ſmall worms of a white colour, and conſiderable length, though not exceeding a horſe-hair in thickneſs. The reaſon that theſe are not found in the ſame place afterwards, probably, is, that they either go out of it, as the inhabitants of many other *galls* do, in order to paſs into their chryſalis ſtate, or elſe that this life in the worm ſtate, and the duration of that in the chryſalis, are both very ſhort, and that they have generally eſcaped in the form of flies before the time that they are ſought for in the leaves. See *Tab. of Inſects*, N° 27. and Reaumur's Hiſt. of Inſ. vol. vi. p. 180.

LIME-*kiln*. See KILN.

LIME-*ammoniacal*, a kind of phoſphorus, invented by Mr. Homberg, and made of ſal ammoniac and lime. See *Ammoniacal* PHOSPHORUS.

LIME, *in Building*. See LEMON.

LIME, *brook*. See BROOK-*Lime*.

LIME-*ſtone*, *lapis calcarius*, is a ſtone of a coarſe grain, which, being burnt in a kiln, makes an ingredient in mortar, plaiſter, &c.

LIME-*tree*, or LINDEN-*tree*, *tilia*, in *Botany*, a genus of the *polyandria monogynia* claſs. Its characters are theſe: the flower has a concave coloured empalement, which is cut into five parts; it has five oblong blunt petals, which are crenated at their points; and many awl-ſhaped ſtamina, terminated by ſingle ſummits; it has a roundiſh germen, ſupporting a ſlender ſtyle of the length of the ſtamina, crowned by an obtuſe five-cornered ſtigma; the germen becomes a thick globular capſule with five cells, opening at the baſe with five valves, each containing one roundiſh ſeed. There are four ſpecies according to Miller, and two in the Linnean ſyſtem.

The ſeveral ſpecies of the *tilia* or *lime-tree* are all eaſily propagated by layers, which in one year will take good root, and ſhould then be removed to the nurſery, planting them at two feet diſtance in rows, and the plants two feet aſunder in each row. The beſt ſeaſon for removing them is Michaelmas. They ſhould remain four or five years in the nurſery, and ſhould afterwards be removed to the places where they are to remain. The ſoil they love is a ſtrong fat loam, in which they grow very faſt.

The timber of the *lime-tree* is uſed by the carvers, becauſe it is a ſoft light-wood; and alſo by architects for framing the models of their buildings: the turners likewiſe uſe it for making light bowls, diſhes, &c. but it is too ſoft for any ſtrong purpoſes. Miller.

Lime-tree flowers are ſuppoſed to have an anodyne and anti-ſpaſmodic virtue: Hoffman ſeems to entertain a great opinion of them in theſe intentions, and as his theory deduces moſt diſeaſes from ſpaſms and ſpaſmodic ſtructures, they are accordingly very frequent in his preſcriptions. He ſays he knew a chronical epilepſy cured by the uſe of an infuſion of them drank as tea.

LIME-*water*. The general opinion of *lime* acting as a cauſtic, and conſuming the bodies it was made to act upon, by means of the great quantity of particles of fire it contained, long denied any preparation of it a place among internal medicines; at length, water poured upon it was found to take in a part of its virtues, and to be a valuable medicine, and very ſafely to be given internally in large quantities.

For this purpoſe, a gallon and a half, or two gallons of water, are poured by degrees upon a pound of freſh-burnt *quick-lime*; the veſſel ſhaken when the ebullition ceaſes, and then ſet by, till the undiſſolved *lime* has ſettled; after which, the liquor is poured off, and paſſed through a filter. Only a ſmall portion of the *lime* is diſſolved by the water, and the remainder gives a ſtrong impregnation to large quantities of freſh water, though not ſo ſtrong as the firſt; great part remaining at laſt undiſſolved: this reſiduum, calcined again, becomes *quick-lime* as before; and by repetitions of this proceſs, nearly the whole may be diſſolved. The ſolution has a ſtrong, ſtyptic taſte; and its effects in chemical mixtures are ſimilar to thoſe produced by *quick*-LIME. In veſſels quite filled with *lime-water*, and exactly cloſed, it may be kept unchanged for many months; but in open veſſels, the calcareous matter ſoon ſeparates from the aqueous fluid, and forms a cruſt or CREAM upon the ſurface, inſipid and indiſſoluble as the earth in its natural ſtate, and again convertible into *quick-lime* by repeated calcination. It is obſerved, that the quantity of calcareous matter that is thus ſeparated from *lime-water*, is even greater than it ought to be, if it was exactly proportioned to the evaporation of the water; the cauſe of which is, that the

quick-lime gradually recovers from the air as much gas as is necessary to deprive it of its properties of *quick-lime*, and to reſtore it to its ſtate of ſimple calcareous earth, mild, effervescing, and unſoluble in water. Hence, *lime-water*, by long expoſure to air, loſes much of its ſtrength, and at laſt becomes almoſt inſipid. It is neceſſary alſo, when this liquor is employed as a menſtruum, to add ſome *quick-lime* in ſubſtance, in order to continue the impregnation of the water with the *lime*.

All *lime* is not equally good for the making this water; but the ſeveral kinds differ, according to the ſubſtances they are made from. In Holland they at this time make *lime* of ſea-ſhells, which they find in vaſt abundance on their ſea-ſhores. This was alſo a practice in the time of Dioſcorides; but the *lime* thus made is not fit for making *lime-water*. The water made from it does not keep long, and is leſs ſtyptic, and ſweetiſh to the taſte, and is greatly inferior to the water made with *lime* burnt from ſtones. The newer the *lime* is, the leſs it has been expoſed to the air, and the drier it has been kept, and finally, the more it has held together without crumbling, or mouldering to powder, the better it is for making *lime*-water. Mem. Acad. Par. 1700.

It appears now from the ingenious Dr. Alſton's experiments, that one part of quick-*lime* is ſufficient for five or ſix hundred parts of water. Water will diſſolve but a certain portion of quick-*lime*; and how much that is cannot be eaſily aſcertained. So far ſeems certain from Dr. Alſton's experiments, that one pound of quick-*lime* is ſufficient for making ſix hundred pounds of good *lime-water*; and that thoſe who with Charas have ſuppoſed, that the ſecond and third *lime-water* is weaker than the firſt, have been led into an error by the ſmall quantity of water they uſed. And it has been generally believed, that in order to obtain good *lime-water*, the quick-*lime* muſt not only be recent and fully calcined, but alſo for one part of quick-*lime* only eight, ten, or, at moſt twelve parts of water taken; as if it could impregnate no more. But the Doctor ſays he has found by many experiments, that it is altogether indifferent whether the water be hot or cold, poured on gradually, or at once, the water poured on the *lime*, or the *lime* thrown into the water; whether the quick-*lime* be in ſhells, or flaked; or even expoſed to the air for ſeveral months, for ſuch quantities of the water as are commonly uſed; and if the quick-*lime* be freſh, whether for one pound of it, eight, ten, twenty, fifty, or five hundred pounds of water be taken. Only it is neceſſary, even for the firſt water after the ebullition is over, to ſtir and mix the *lime* with the water, and allow it time to impregnate itſelf; which is beſt known by the cruſt formed on its ſurface. Filtration indeed is not neceſſary, if it be not to prevent any undiſſolved *lime* being mixed with it; or cruſts diminiſhing its tranſparency.

The Doctor, for his own uſe, poured about eight pounds of boiling water upon a pound of ſtone quick-*lime* in a glazed earthen veſſel. He drank about a pint and an half of this *lime-water*, daily for about ſixteen months; filling up the veſſel, when neceſſary, with freſh water, ſometimes hot and ſometimes cold, without obſerving any difference in the *lime-water*, which he conſtantly filtered through grey paper, before he drank it. He obſerved, that the *lime* was not exhauſted after two years and two months, nor was the water ſenſibly weaker, when it ſtood a ſufficient time on the *lime*, which he knew by the cruſts that were formed. But the *lime* becoming conſiderably lighter, after it is long thus uſed, it at length requires ſeveral days to ſubſide, and form the cruſts, and after the cruſts are formed, it does not leave half the water clear, as it did at firſt. On the whole, this ſingle pound of *lime* afforded the Doctor about ſix hundred pounds of *lime-water*. He adds, that having taken *lime-water* made indifferently of *lime* ſtone, or of chalk, or of ſhells, and ſometimes made of all the three together, he was never able to diſcover any difference in their effects. But ſo much *lime-water* is not to be obtained from *quick-lime*, unleſs it be freſh, completely calcined, and free from heterogeneous ſubſtances; for if defective in any of theſe, it will yield proportionably leſs *lime-water*. Lewis's Mat. Med. and Chem. Dict.

M. Butlet has an ample account of its effects in the French Memoirs, chiefly from his own experience. But he obſerves, it ſucceeded much better in Holland, &c. than in France. It is a powerful alterant, and, like a pure alkaline water, ſuited to blunt and deſtroy acid ferments, which are the principles of all obſtructions, and the cauſe of moſt chronic diſeaſes. Its principal uſe is in cachexies, green-ſickneſs, dropſy, ſcurvy, obſtructions of the liver, ſpleen, &c.

Experience has the ſtrongeſt teſtimony to be an excellent medicine in many caſes; in the gravel and ſtone particularly. And it has alſo been found very ſerviceable in the gout, in habitual relaxations of the bowels, and in other caſes of relaxation. In ſome kinds of the ſcurvy likewiſe it is of uſe; and is often applied with ſucceſs, externally, to ulcers, &c.

Fabricius ab Aquapendente aſſures us, he cured a ſchirrous ſpleen, and the dropſy, by a continued uſe of ſponges dipped in common *lime-water*, and placed near the part affected. Boyle's Works abr. vol. i. p. 80.

Lime-water, which was long looked on as a cauſtic, was, in the laſt century, found to be a very ſafe and valuable remedy. It is uncertain who firſt ventured to give it internally; but Willis, Bates, and Moreton, ſeem to have uſed it much.

Lime-water kills worms, and many other, if not all, inſects. Hence Dr. Alſton concludes, it might prove a good anthelmintic for children; and experience has confirmed this notion.

It is probable, that *lime-water* may be of great uſe in long ſea-voyages, in preventing the corruption of water, or inſects breeding in it, as well as curing the diſeaſes to which ſea-faring people are moſt ſubject. The experiment is certainly ſafe, eaſy, and attended with no expence; one pound of freſh well-burnt quick-lime of any kind being enough for a hogſhead of water, which may not only be uſed for common drink by the diſeaſed, or for prevention by the healthy; but alſo by boiling, and expoſing it to the air for a ſhort time, it may be reſtored to ſweet water, and uſed in dreſſing the victuals of the moſt delicate.

The virtues of *lime-water* do not depend on its abſorbency; and it may as juſtly be called antalkaline, as antacid.

Lime-water prevents or long protracts the putrefaction of animal ſubſtances. Dr. Alſton alſo thinks that *gun-lime* in a ſhip's well, would effectually prevent the corruption of the water, and conſequently the putrid ſtreams, or foul air, thence ariſing, which ſometimes prove fatal to the crew.

The virtues of *lime-water* outwardly applied in many diſeaſes of the ſkin, in excoriations, ulcers, gangrenes, &c. are well known. Perhaps there is not a better gargariſm for ſeveral ſorts of ſores in the mouth and throat than *lime-water*. It has alſo been known to be of great uſe in the tooth-ach. Inwardly taken, *lime-water* has all the virtues of pure element, which are not a few; and on which probably depend the good effects of mineral waters, more than on the minerals they contain. Dr. Alſton never found it cauſed thirſt; on the contrary, he found it quenched thirſt, as well as ſimple water, and cuſtom rendered it agreeable. *Lime-water* is notably detergent and attenuating, even more ſo than ſoap itſelf, of mucous, viſcid, and other animal ſordes, which makes it preferable, in many caſes, to the pureſt, as well as to mineral waters. In a word, *lime-water* may be ſaid, in general, to purify the blood with as good reaſon, as any one medicine whatever, eſpecially from any putrid, purulent, or ſcorbutic foulneſs.

Dr. Lewis obſerves, that *lime-water*, drunk to the quantity of a quarter of a pint three or four times a day, has been found ſerviceable in ſcrophulous complaints, fluxes, ſeminal weakneſſes, and other diſorders proceeding from an impurity of the fluids, or laxity and debility of the ſolids. It generally promotes urine; oftentimes the criticular diſcharge; and where the ſtomach is oppreſſed with viſcid phlegm, expectoration. If for the moſt part binds the belly, and ſometimes occaſions a troubleſome coſtiveneſs, unleſs this effect be occaſionally prevented againſt by the interpoſition of proper laxatives. It anſwers beſt in cold, ſtuggiſh, phlegmatic, and corpulent habits; and is to be uſed more cautiouſly in hot, bilious diſpoſitions, and where the patient is much emaciated, or the appetite weak, and at the time of any critical or periodical evacuation. It has been cuſtomary to impregnate *lime-water* with different materials, partly for rendering it more acceptable to the palate and ſtomach, and partly for improving its medicinal efficacy againſt cutaneous diſeaſes. The college of Edinburgh directs, in this view, three ounces of the ſhavings of the wood and bark of ſaſſafras, one ounce and a half of ſhaved liquorice, and four drams and a half of bruiſed nutmegs; the college of London, half an ounce of ſaſſafras-bark, and one ounce of liquorice, with the addition, in ſome caſes, of four ounces of raſped guaiacum wood, and three drams of coriander ſeeds; to be macerated for four days in three quarts of *lime-water*, and the liquor ſtrained off for uſe. Theſe infuſions are taken in the ſame quantities as the ſimple *lime-water*, by themſelves, or with the addition of milk. Lewis's Mat. Med.

But Dr. Macbride obſerves, that the activity of *lime-water* is impaired by infuſing vegetable ſubſtances therein, which contain much fixed air, ſuch as the guaiacum or ſaſſafras; for theſe woods, abounding in reſin, give out their cementing principle, which, uniting with the diſ-

solved *quick-lime*, reſtores it to its original ſtate of an inactive calcareous earth: therefore, when it is intended that theſe woods, or any other ſubſtance of the like nature, ſhould give out their virtue to *lime-water*, and that the water ſhould, at the ſame time, contain its due proportion of diſſolved *lime*, ſome *quick-lime* ought to be added, during the time of maceration. He alſo obſerves, that as milk contains a large proportion of fixed air, it ought not to be mixed with *lime-water*, ſince it muſt neceſſarily take off from its activity. To the ſame purpoſe, Dr. Alſton has obſerved, that there is ſcarce any thing that is uſually mixed and given along with *lime-water*, that does not, more or leſs, deſtroy its efficacy; for which reaſon he recommended it always to be taken alone. Macbride's Eſſays, p. 250. 251.

It is obſerved by Dr. Lewis, that *lime-water* diſſolves, by the aſſiſtance of heat, mineral ſulphur, vegetable oils and reſins, and animal fats. It extracts alſo, in the cold, the virtues of ſundry reſinous and oily vegetables, and diſſolves thick phlegm, or mucous matters, and the curd of milk, with which laſt it forms a white liquid, nearly ſimilar to milk in its natural ſtate. But the diſſolvent power of *quick-lime* has been evinced by Dr. Macbride, and ſhewn to extend to a variety of different ſubſtances, as camphor, myrrh, gum guaiacum, aſa fœtida, aloes, caſtor, balſam of Tolu, maſtich, jalap, and the cortex Peruvianus, which were found to yield ſtrong ſolutions and tinctures; and theſe he ſays, are more elegant medicines, and perhaps may be found more efficacious than the ſpirituous tinctures, ſince they will never become turbid, or ſeparate on being mixed in any watery vehicle. And ſince the ſolvent power of *quick-lime* is found to depend on its depriving certain ſubſtances of that fixed air, which is their cementing principle, it was natural to imagine that it might be uſefully applied to the ſolution of the human calculus or ſtone.

Of all the various ſubſtances examined by Dr. Hales, with a view of determining their reſpective quantities of fixed air, the human calculus was found to contain the largeſt proportion; above one half of this maſs conſiſting of fixed air. Neverthleſs, if the cauſtic alkali, or *lime-water*, could be ſafely conveyed to it, theſe would abſorb the fixed air, and the earthy parts, deprived of what bound them together, muſt preſently fall to pieces. That *lime-water* is lithontriptic has been ſhewn ſufficiently by Dr. Hales, and more fully by Dr. Whytt. See his Eſſay on the Virtues of *Lime-water*, in the Cure of the Stone, and Edinb. Eſſ. &c. vol. i. art. 13. p. 383. vol. v. art. 69.

This gentleman prefers calcined oyſter-ſhell *lime-water* to any other; which, he ſays, proves a more active menſtruum for this concrete, than that made from the ſtone *lime*; the diſſolving power of the oyſter-ſhell *lime-water* ſeeming, from Dr. Whytt's experiments, to be more than double to that of the ſtone *lime-water*. Dr. Alſton ſeems to think this a matter of indifference, and was himſelf cured chiefly by the ſtone *quick-lime water* before mentioned. This lithontriptic quality of *lime-water* has been farther confirmed by Dr. Alſton, who has ſhewn the efficacy of *lime-water* in this reſpect, not only when made by the firſt infuſion, and aſſiſted by artificial heat, but even after fifty or more infuſions, and in the common air. The doctor thinks that the energy of *lime-water* in this caſe probably conſiſts in its penetrating detergency, whereby inſinuating itſelf among the ſolid parts of the calculi, or into their pores, it ſeparates them, or diminiſhes their cohæſion, but does not diſſolve them. See LITHONTRIPTICS.

But the efficacy of *quick-lime* and cauſtic alkali in this intention, is now known to depend principally, if not entirely, on its power of abſorbing the air, which binds calculous ſubſtances together. However, the alkali, when combined with oil, and made into ſoap, is not only ſo greatly obtunded thereby, as to loſe much of its power, but the ſoap itſelf is ſo naſeous, that few perſons can be induced to take it in a quantity ſufficient to prove of much effect: it would, therefore, be a happy diſcovery if any vehicle could be found out that would ſheathe the acrimony of the cauſtic alkali, ſo as to allow it to be taken in large and continued doſes. Poſſibly, ſays Dr. Macbride, veal broth, or a decoction of marſhmallow roots, might be found to anſwer this purpoſe; and *lime-water* might be taken at the ſame time, which would not at all interfere with the operation of the alkali, but rather add to its activity. Dr. Chittick's noſtrum, which is found, after a perſeverance of ſome months, actually to diſſolve the ſtone, is ſaid to be nothing more than the cauſtic alkali, given in veal broth. But *lime-water*, when taken alone, muſt often fail in producing any conſiderable effect as a lithontriptic, becauſe it will loſe much of its power, as Dr. Macbride has ſhewn, from the fixed air of the alimentary ſubſtances in the firſt paſſages, who, therefore, recommends it to be drank when the ſtomach is empty; and alſo, as Dr. Whytt and Dr. Macbride have proved by experiments, from the fixed air of the urine itſelf, which will ſaturate great part of the *quick-lime*, even when it hath reached the bladder. Macbride's Eſſays, edit. 5. paſſim.

Since there is but a ſmall proportion of *lime* in the water, it may be thought that taking a few grains of the *quick-lime* in ſubſtance would prove much more effectual in the ſtone, than large quantities of *lime-water*. But this is a miſtake; and hence Mrs. Stephens's egg-ſhells and ſnail-ſhells, if burnt to *quick-lime*, can never be equally ſucceſsful with *lime-water* for the STONE.

As for the *aqua benedicta compoſita*, or *compound lime-waters*, they are not to be compared with ſimple *lime-water* in the graſs; nor, in Dr. Alſton's opinion, in any diſeaſe requiring this water.

The doctor adds, in his appendix, that though he cannot yet determine how far *lime-water* may be proper, even in acute diſtempers, yet he has found it ſafe in ſeventh colds; and by the caſes he there mentions, it ſeems probable that *lime-water*, by its diluent and diuretic qualities, may prove more uſeful in fevers, than is at preſent believed.

However this may prove on farther trials, it may be ſaid, in general, that *lime-water* is diluent, detergent, antiſeptic, anthelmintic, diuretic, and vulnerary; uſeful in all diſeaſes proceeding from, or accompanied with obſtructions in the bowels or glands, viſcid phlegm, calculous concretions, or putrefaction; and commended for the ſcurvy, ſcrophulæ, gravel, conſumptions, empyema, aſthma, arthritis vaga, cutaneous ſwellings, diabetes, fluor albus, fluxes, &c. and outwardly for diſeaſes of the ſkin, ulcers, gangrenes, &c. It may be taken to the quantity of a pound, once, twice, or thrice a day; or uſed for common drink. See Dr. Alſton's Diſſertation on *Quick-lime*, and *Lime-water*, Edinb. 1752.

LIMER, or LIME-*hound*. See BLOOD-HOUND.

LIMEUM, in *Botany*, a genus of the *heptandria digynia* claſs. Its characters are, that the calyx is compoſed of five leaves; that it has five equal petals; and that the fruit is a globular capſule, with two cells. There is only one ſpecies.

LIMIT *of diſtinct viſion*, in *Optics*. See *Diſtinct* VISION.

LIMITATION, *limitatio*, in *Law*, is a certain time aſſigned by ſtatute, within which an action muſt be brought; and *limitation* of time is two-fold; viz. to make title to an inheritance by the common law; and in writs by ſeveral ſtatutes. There is a *limitation* in real and perſonal actions; and in the former, he that will ſue for any lands or hereditaments, ought to prove that he or his anceſtors were ſeiſed of the lands ſued for by writ of aſſiſe, or he cannot maintain his action; and this is called *limitation* of aſſiſe. Stat. Weſt. 1.

The 32 Jac. I. cap. 16. ordains, that all writs of *formedon*, &c. for title to lands *in fee*, ſhall be ſued and proſecuted within twenty years after the title ſued; but there is a proviſo in the ſtatutes, to relieve infants, feme covets, perſons beyond ſea, or in priſon, and the heirs of ſuch perſons, ſo as they commence their ſuits within the times limited after their impediments are removed. By ſtatute, actions of debt, actions upon the caſe, except for words, actions of account (except concerning merchandize), of detinue, trover and treſpaſs, are to be commenced within ſix years after the cauſe of action, and not after; actions of aſſault and battery, wounding and impriſonment, within four years; and for ſlander within two years after the cauſe of action, &c. 21 Jac. I. cap. 16.

LIMITATION *of eſtate*, in a legal ſenſe, imports how long the eſtate ſhall continue, or in rather a qualification of a precedent eſtate. As where one doth give lands to a man to hold to him and his heirs male, and to him and the heirs female, &c. here the daughters ſhall not have any thing in it, ſo long as there is a male; for the eſtate to the heirs male is firſt limited. Co. Litt. 313.

LIMITATION *of the crown*. The ſtatutes 1 W. & M. cap. 8. 12 W. III. cap. 2. and 1 & 2 Ann. cap. 17. 4 Ann. cap. 8. &c. are acts for the *limitation of the crown*, and veſting it on proteſtant heirs in the houſe of Hanover. See CROWN.

LIMITED *problem*, is that which admits but of one ſolution, or which can only be ſolved one way; as to make a circle paſs through three points given, not lying in a right line, to deſcribe an equilateral triangle on a line given, &c. See PROBLEM, and DETERMINATE.

LIMITROPHOUS *column*. See COLUMN.

LIMITS, in *Mathematics*, is ſometimes uſed, in general, for quantities, one of which is greater, and the other leſs than another quantity. Thus, in the quantities, *a*, *x*, *b*, if *a* be leſs than *x*, and *b* be greater than *x*, *a* and *b* are ſaid to be *limits* of *x*. The word occurs in this

ſenſe, when we ſpeak of the *limits* of the roots of equations.

Sometimes a quantity is ſaid to be a *limit* between two others, when it is greater than the one and leſs than the other. So a ratio is ſaid to be a *limit* between two other ratios, when it is greater than the one and leſs than the other.

But *limit* is often uſed in a more reſtricted ſenſe; thus, when a variable quantity approaches continually to ſome determinate quantity, and may come nearer to it than to have any given difference, but can never go beyond it; then is the determinate quantity ſaid to be the *limit* of the variable quantity.

Hence, the circle may be ſaid to be the *limit* of its circumſcribed and inſcribed polygons; becauſe theſe, by increaſing the number of their ſides, can be made to differ from the circle leſs than by any ſpace that can be propoſed, how ſmall ſoever.

The *limit* of a variable ratio, is ſome determinate ratio, to which the variable ratio may continually approach, and come nearer to it than to have any given difference, but can never go beyond it. Hence, the ratio of the ordinate to the ſub-tangent of a curve, is ſaid to be the *limit* of the variable ratio of the differences of the ordinates, to the differences of the abſciſſæ.

The word *limit*, in this ſenſe, ſignifies the ſame as what Sir Iſaac Newton calls a firſt or prime, and a laſt or ultimate ratio.

There are two caſes of a variable quantity, or variable ratio, tending to ſuch a *limit*, as we have been deſcribing. In the firſt caſe, the variable quantity, or ratio, will not only approach to its *limit* nearer than any given difference, but will actually arrive at its *limit*.

In the ſecond caſe, the variable quantity, or ratio, will only approach its *limit* within leſs than any given difference, but will never actually arrive at it.

Sir Iſaac Newton, to avoid the harſhneſs of the hypotheſis of indiviſibles, and the tediouſneſs of demonſtrations, according to the method of the ancients, by deductions *ad abſurdum*, has premiſed ſeveral lemmata, in the firſt ſection of the firſt book of his principles, relating to the firſt and laſt ſums, and ratios of naſcent and evaneſcent quantities; that is, to the *limits* of ſums and ratios. This doctrine chiefly depends on the firſt of thoſe lemmata; the words of which are, *Quantitates ut & quantitatum rationes, quæ ad æqualitatem tempore quovis finito conflanter tendunt, & ante finem temporis illius propius ad invicem accedunt quam pro data quavis differentia, fiunt ultimo æquales.*

The learned gentlemen, who have written in defence of Sir Iſaac, againſt the author of the Analyſt, are not agreed among themſelves, as to the preciſe meaning of this lemma. One of theſe gentlemen ſays, that the genuine meaning of this propoſition is, that thoſe quantities are to be eſteemed ultimately equal, and thoſe ratios ultimately the ſame, which are perpetually to each other, in ſuch a manner, that any difference, how minute ſoever, being given, a finite time may be aſſigned, before the end of which, the difference of theſe quantities, or ratios, ſhall become leſs than that given difference. See Preſ. State of the Rep. of Letters for Oct. 1735, and for Oct. 1736.

What Sir Iſaac Newton intends we ſhould underſtand by the ultimate equality of magnitudes, and the ultimate identity of the ratios propoſed in this lemma, will be beſt known from the demonſtration annexed to it. By that it appears, Sir Iſaac Newton did not mean, that any point of time was aſſignable, wherein theſe varying magnitudes would become actually equal, or the ratios really the ſame; but only that no difference whatever could be named, which they ſhould not paſs. The ordinate of any diameter of an hyperbola, is always leſs than the ſame continued to the aſymptote; yet the demonſtration of this lemma can be applied, without changing a ſingle word, to prove their ultimate equality. The ſame is evident from the lemma immediately following, where parallelograms are inſcribed, and others circumſcribed to a curvilinear ſpace. Here the firſt lemma is applied to prove, that by multiplying the number, and diminiſhing the breadth of the parallelograms *in infinitum*, that is, perpetually and without end, the inſcribed and circumſcribed figures become ultimately equal to the curvilinear ſpace, and to each other; wherein, it is evident, that no point of time can be aſſigned, wherein they are actually equal; to ſuppoſe this were to aſſert, that the variation aſcribed to the figures, though endleſs, could be brought to a period, and be perfectly accompliſhed; and thus we ſhould return to the unintelligible language of indiviſibles. The excellence of this method conſiſts in making the ſame advantage of this endleſs approximation towards equality, as by the uſe of indiviſibles, without being involved in the abſurdities of that doctrine. In ſhort, the difference between theſe two may be thus explained.

There are but three ways in nature of comparing ſpaces: one is by ſhewing them to conſiſt of ſuch, as by impoſition on each other will appear to occupy the ſame place: another is, by ſhewing their proportion to ſome third; and this method can only be directly applied to the like ſpaces as the former; for this proportion muſt be finally determined by ſhewing when the multiples of ſuch ſpaces are equal, and when they differ: the third method to be uſed, where theſe other two fail, is by deſcribing upon the ſpaces in queſtion ſuch figures as may be compared by the former methods; and thence deducing the relation between thoſe ſpaces, by that indirect manner of proof, commonly called *deductio ad abſurdum*; and this is as concluſive a demonſtration, as any other, it being indubitable, that thoſe things are equal, which have no difference. Thus Euclid and Archimedes demonſtrate all they have written concerning the compariſon and menſuration of curvilinear ſpaces. The method advanced by Sir Iſaac Newton for the ſame purpoſe, differs from their's, only by applying this indirect form of proof to ſome general propoſitions, and from thence deducing the reſt by a direct form of reaſoning. Whoever compares the fourth of Sir Iſaac Newton's lemmas with the firſt, will ſee, that the proof of the curvilinear ſpaces, there conſidered, having the proportion named, depends wholly upon this, that if otherwiſe the figure inſcribed within one of them, could not approach, by ſome certain diſtance, to the magnitude of that ſpace; and this is preciſely the form of reaſoning, whereby Euclid proves the proportion between the different circles. As this method of reaſoning is very diffuſively ſet out in the writings of the ancients; and Sir Iſaac Newton has here expreſſed himſelf with that brevity, that the turn of his argument may poſſibly eſcape the unwary, the reading of the ancients muſt be the beſt introduction to the knowledge of his method. The impoſſible attempt of comparing curvilinear ſpaces, without having any recourſe to the forementioned indirect method of arguing, produced the abſurdity of indiviſibles.

As the magnitudes, called in this lemma ultimately equal, may never abſolutely exiſt under that equality; ſo the varying magnitudes holding to each other the variable ratios here conſidered, may never exiſt under that, which is here called their ultimate ratio. Of this Sir Iſaac Newton gives an inſtance, from lines increaſing together by equal additions, and having from the firſt a given difference. For the ultimate ratio of theſe lines, in the ſenſe of this lemma, as Sir Iſaac Newton himſelf obſerves, will be the ratio of equality, though theſe lines can never have this ratio; ſince no point of time can be aſſigned, when one does not exceed the other.

In like manner, the quantities called by Sir Iſaac Newton vaniſhing, may never ſubſiſt under that proportion here eſteemed their ultimate.

In the caſe of drawing tangents to curves, where the ordinate bears the ſame proportion to the ſubtangent, as that wherewith the difference of the ordinates, to the difference of the abſciſſæ, vaniſh; theſe lines muſt not be conceived, by the name of an evaneſcent, or any other appellation, ever to ſubſiſt under that proportion; for ſhould we conceive theſe lines, in any manner, to ſubſiſt under this proportion, though at the inſtant of their vaniſhing, we ſhall fall into the unintelligible notion of indiviſibles, by endeavouring to repreſent, to the imagination, ſome inconceivable kind of exiſtence of theſe lines between their having a real magnitude, and becoming abſolutely nothing. Sir Iſaac Newton was himſelf apprehenſive, that this miſtake might be made; for as he thought fit (in compliance with the bad taſte which then prevailed) to continue the uſe of ſome looſe and indiſtinct expreſſions reſembling thoſe of indiviſibles, for which he has himſelf apologized, he expreſsly cautions us againſt miſinterpreting him in this manner, when he ſays: *Si quando dicam quantitates quam minimas vel evaneſcentes, vel ultimas, cave intelligas quantitates magnitudine determinatas, ſed cogita ſemper diminuendas ſine limite.* Thus expreſsly has he declared to us, that vaniſhing quantities, or whatever other leſs accurate appellation he names them by, are to be conſidered as indeterminate quantities bearing to each other under their different magnitudes, different proportions; which the quantities themſelves can never obtain, and the *limit* of theſe proportions is that, for the ſake of which theſe quantities are conſidered: inſomuch, that ſince theſe quantities have different proportions, while they obtain the name of vaniſhing quantities, the term ultimate is neceſſarily added to denote that proportion, which is the *limit* of an endleſs number of varying ones. The like remark is neceſſary, when theſe quantities are conſidered in the other light, as ariſing before the imagination: for then the

propor-

proportion intended must be specified, by calling it the first, or prime proportion of these quantities. And as this additional epithet is necessary to express the proportion intended, so it is absurd to apply it to the quantities themselves; as Sir Isaac Newton says, there are *rationes primæ quantitatum nascentium*, but not *quantitates primæ nascentes*. Philosoph. Transactions, N° 342. p. 205.

So that, according to the author we have been quoting, all the examples given by Sir Isaac in the before mentioned section, are to be understood of such *limits* or ultimate ratios, as are never attained to by the quantities and ratios limited, but to which these may approach indefinitely, that is, so as to differ less than by a given quantity.

On the other hand, a learned gentleman, who assumed the name of *Philalethes Cantabrigiensis*, thinks that Sir Isaac means, by the words of the lemma, and proves, in his demonstration, not that the quantities, or ratios are barely to be considered as ultimately becoming equal, or are to be esteemed as ultimately equal; though, in reality, they can never have that proportion to each other; but that they do at last become actually, perfectly, and absolutely equal. Pres. State of the Republic of Letters for November 1735. p. 371.

He also distinguishes, as above, between quantities and ratios which arrive at their *limits*, and those which do not. And it is insisted on, that every one of the examples given in the lemmata of this first section of the first book of Sir Isaac's Principles, are of such quantities and ratios as actually arrive at their respective *limits*; nor is there an instance there given of a quantity, or ratio, which never arrives at its *limit*, except one at the latter end of the scholium of this section (and that by way of illustration of a particular objection only) of two quantities, having a given difference, and being equally increased, *ad infinitum*, and whose ratio, it is admitted, never arrives at its *limit*. But decreasing quantities may really, and, in fact, be diminished *ad infinitum*: for they may vanish and come to nothing. The ratio therefore of these, says he, may arrive at its *limit*, though that of the others cannot.

Neither are these learned gentlemen agreed as to the sense of the word *vanishing or evanescent*, in the scholium of this first section of Sir Isaac's Principles.

The question is, whether the quantities that vanish, are understood to spend some finite time in vanishing, or to vanish in an instant, or point of time; and consequently, whether they bear to one another an infinite number of different successive ratios during the vanishing, or one ratio only, at the point, or instant of their evanescence.

This last is the sense in which *Philalethes* takes the word evanescent, or vanishing; and the dispute, on this head, as he observes, is of no other consequence, than to determine, whether the sense in which he uses the word be agreeable to Sir Isaac Newton's. For, if the quantities vanish in an instant, I take the only ratio with which they vanish; or they spend a finite time in vanishing, and I take the last of the ratios, which they successively bear to one another during that time; till the ratio, taken in either of these cases, will be one and the same. Pres. State of the Repub. of Letters for November 1735. p. 383. 384.

We cannot pretend to give the whole detail of this controversy, but must refer the curious to the *Present State of the Republic of Letters for 1735*. We shall only observe, that this disquisition is partly critical and partly scientifical. The critical inquiry is into the sense of Sir Isaac, so far as it may be determined from his own words, and here we cannot help thinking that this is somewhat doubtful. The other inquiry is about the true or scientifical notion, upon which this doctrine ought to be founded. With respect to which we shall only ask two questions, which every reader may resolve for himself, to wit, whether the conception or notion he has of the ratio or proportion of evanescent quantities, at the point or instance of their evanescence, be more clear and distinct than the notion of infinitesimals? And whether the notion of inscribed or circumscribed polygons to any curve, attaining their last form, and thereby coinciding with their curvilinear *limit*, be more clear and distinct than the notion of polygons of an infinite number of sides, in the method of infinitesimals?

Before we leave this subject, it may be proper to give the sentiments of an eminent mathematician about the doctrine of *limits*, or of prime and ultimate ratios, and to shew the connection of this doctrine with that of fluxions. Mr. Maclaurin, in his Treat. of Flux. art. 502. Sir Isaac Newton considers the simultaneous increments of flowing quantities as finite, and then investigates the ratio, which is the *limit* of the various proportions which those increments bear to each other, while he supposes them to decrease together till they vanish; which ratio is the same with the ratio of the fluxions. In order to discover this *limit*, he first determines the ratio of the increments in general, and reduces it to the most simple terms, so as that (generally speaking) a part at least of each term may be independent of the value of the increments themselves; then, by supposing the increments to decrease till they vanish, the *limit* readily appears.

For example, let a be an invariable quantity, x a flowing quantity, and o any increment of x; then the simultaneous increments of xx and ax will be $2xo+oo$ and ao, which are in the same ratio to each other, as $2x+o$ is to a. This ratio of $2x+o$ to a, continually decreases while o decreases, and is always greater than the ratio of $2x$ to a, while o is any real increment; but it is manifest, that it continually approaches to the ratio of $2x$ to a as its *limit*; whence it follows, that the fluxion of xx is to the fluxion of ax, as $2x$ is to a. If x be supposed to flow uniformly, ax will likewise flow uniformly, but xx with a motion continually accelerated: the motion with which ax flows, may be measured by aa; but the motion with which xx flows is not to be measured by its increment $2xo+oo$, but by the part $2xo$ only, which is generated in consequence of that motion; and the part oo is to be rejected, because it is generated in consequence only of the acceleration of the motion with which the variable square flows, while o, the increment of its side, is generated: and the ratio of $2xo$ to ao is that of $2x$ to a, which was found to be the *limit* of the ratio of the increments $2xo+oo$ and ao. See FLUXION.

It is objected against Sir Isaac Newton's method of investigating this *limit*, that he first supposes that there are increments; that when it is said *let the increments vanish*, the former supposition is destroyed, and yet a consequence of this supposition, i. e. an expression got by virtue thereof, is retained. But the suppositions that are made in this method of investigating the *limit*, are not so contradictory as this objection seems to import. He first supposes that there are increments generated, and represents their ratio by that of two quantities, one of which is given so as not to vary with the increments. If he had afterwards supposed that no increments had been generated, this indeed had been a supposition directly contradictory to the former. But when he supposes those increments to be diminished till they vanish, this supposition surely cannot be said to be to contradictory to the former, as to hinder us from knowing what was the ratio of those increments, at any term of the time while they had a real existence; how this ratio varied, and to what *limit* it approached, while the increments were continually diminished? On the contrary, this is a very concise and just method of discovering the *limit* which is required.

It is to be observed, that the limiting, prime, or ultimate ratio of increments, strictly speaking, is not the ratio of any real increments whatsoever. But as the tangent of an arch is the right line that *limits* the position of all the secants that can pass through the point of contact, though strictly speaking it be no secant; so a ratio may *limit* the variable ratios of the increments, though it cannot be said to be the ratio of any real increments. The ratio of the generating motions may be likewise said to be the last or ultimate ratio of the increments, while they are supposed to be diminished till they vanish, for a like reason. It may just be added, that there being two cases of variable quantities and ratios tending to a *limit*, it might have conduced to perspicuity, and prevented disputes, to have distinguished these different *limits* by some addition. As in the first case to have called it a *limit* or ultimate ratio *inclusive*; because the *limit* is the last of the quantities or ratios limited: and in the second, to have called it a *limit* or ultimate ratio *exclusive*; because the quantities limited never attain to the *limit*, though they approach to it indefinitely.

This distinction may perhaps receive some further illustration from the following example. It is known that the osculatory circle is a circle that touches a curve so closely that no other circle can be drawn through the point of contact between them, all other circles falling within or without them both; and hence the osculatory circle is supposed to have an equal curvature with the curve at that point. See Mr. Mac-Laurin's Flux. art. 364. Now if we conceive the osculatory circle at the end of the great axis of an ellipsis, it will fall entirely within the ellipsis; and the curvatures of the ellipsis and osculatory circle may both be said to be *limits* of the curvatures of all the circles falling wholly within, and touching the ellipsis at the end of its great axis. But the term *limit* will not in both cases have precisely the same meaning: for the osculatory circle is a *limit exclusive*, being the last of the circles limited; and the ellipsis is a *limit inclusive*, none of the circles limited ever coinciding with it. As to the circles which fall wholly without the ellipsis, and touch

toneh it at the end of its great axis, they have no *limit inclusive*, no circle touching the ellipsis so closely, that no other can pass between; the only *limit* here is *exclusive*, the ellipsis itself.

The contrary of this happens at the end of the leſſer axis. At any other point of the ellipsis one half of every oſculatory circle is a *limit inclusive* of the ſegments of the circles that fall within, and the other half is a *limit inclusive* of thoſe that fall without.

May we not aſk, if a curve is the *limit* of its inſcribed or circumſcribed polygons in any other ſenſe, than the curvature of the ellipſis is the *limit* of the curvatures of the circles before deſcribed, which approach nearer and nearer to the curve, but never coincide with it? It is true we hear it often ſaid, that the oſculatory circle is coincuveal, and ſo coincides with the ellipſis; but this ſeems a conſequence of the language of infiniteſimals. It would be more accurate to ſay, that the curvature of the ellipſis is the *limit inclusive* of all the before mentioned circles, and that the oſculatory circle is their *limit inclusive*. That excellent geometer, Mr. Simſon, in his Conic Sections, lib. v. prop. 36. cor. ſays only, after demonſtrating the chief property of the oſculatory circle, that *eadem ratione cum ellipſe tanica curvaturam dicitur*, giving this only as an appellation, but not as a propoſition. See on the ſubject of this article, Robins's Diſc. on Fluxions, in his Tracts, vol. ii.

LIMITS, in a *Military Senſe*, denote the diſtance which a century is allowed on his poſt, viz. fifty paces to the right, and as many to the leſt; and though the weather be ever ſo bad, he muſt not get under cover.

LIMITS *of a planet*, its greateſt excurſions or diſtances from the ecliptic. See PLANET.

LIMITANEI, among the Romans, an appellation given to the ſoldiers who were ſtationed on the frontiers of the empire.

LIMITOTROPH, among the Romans, the ſame with LIMITANEI.

LIMMA, Λημμα, *reſiduum*, in the *Ancient Muſic*, is the difference of the diateſſaron and the ditonus. It is expreſſed by $\frac{243}{256}$.

Euclid demonſtrates it to be leſs than the hemitone. Boethius calls the *limma*, *hemitonium minus*. Wallis's Appendix to Ptolemy's Harmon. p. 169, 170. Ibid. p. 170.

The *limma* here defined is that of Ptolemy. Modern muſicians have applied this name to ſeveral other intervals, ariſing from the ſubtraction of ſemi-tones from the tone major. Thus the difference between the ſemitone minor and the tone major which is $\frac{9}{10} : \frac{15}{16} = \frac{27}{25}$ is by Mr. Euler called *limma majus*; and the difference between the ſemitone major and tone major, he calls *limma minus*. This laſt is expreſſed by $\frac{15}{16} : \frac{24}{25} = \frac{125}{128}$. The octave is nearly equal to nine greater *limmas*, and to thirteen leſſer. Euler, Tentam. Nov. Theor. Muſic. p. 107, 108. Ibid. p. 108. See INTERVAL.

LIMNING, the art of painting in water-colours.

In which ſenſe *limning* ſtands contradiſtinguiſhed from PAINTING, properly ſo called, which is done in oil-colours.

Limning is much more the ancient kind of painting. Till a Flemiſh painter, one John Van Eyck, better known by the name of John of Bruges, found out the art of painting in oil, the painters all painted in water, and in freſco, both on their walls, or wooden boards, and elſewhere. When they made uſe of boards, they uſually glued a fine linen cloth over them, to prevent their opening, then laid on a ground of white; and, laſtly, they mixed up their colours with water and ſize, or with water and yolks of eggs, well beaten with the branches of a fig-tree, the juice whereof thus mixed with the eggs; and with this mixture they painted their pieces.

In *limning*, all the uſual colours are proper enough, excepting the white made of lime, which is only uſed in freſco. But the azure and ultramarine muſt always be mixed up with ſize, or with glair, becauſe the yolks of eggs give yellow colours a greenith tincture. But there are always applied two lays of hot ſize, before the colours, mixed even with ſize, are laid on; the compoſition made with eggs, and the juice of the fig-tree, being only uſed for touching up and finiſhings, and to prevent the neceſſity of having a fire always at hand to keep the ſize hot; yet it is certain, that the ſize-colours hold the beſt, and are accordingly always uſed in cartoons, &c. This ſize is made of ſhreds of thin leather, or of parchment.

To *lime* on linen, they cheriſe that which is old, half-worn, and aloſe. This they cover with white leaf, or a fine plaiſter beaten up with ſize; which once dry, they go over it with a layer of the ſame ſize.

The colours are all ground in water, each by itſelf; and in proportion, as they are required in working, are diluted with ſize-water. If the yolks of eggs are deſired, they dilute them with a liquor made of equal quantities of common water and vinegar, with the yolk, white, and ſhell of an egg, and the ends of the little branches of a fig-tree cut ſmall, all well beaten together in an earthen pan.

If it be deſired to varniſh the piece when finiſhed, they go over it with the white of an egg well beaten, and then with varniſh. This, however, is only to preſerve it from the wet; for the great advantage of *limning* conſiſts in its being without gloſs; becauſe all its colours, thus void of luſtre, may be ſeen in all kinds of lights; which colours in oil, or covered with varniſh, cannot.

LIMNITIS, a word uſed by the ancients to expreſs the concretion round reeds, or water plants, by ſome called AGARIC, or ſomewhat analogous to that.

LIMOCINCTI, among the Romans, a kind of prieſts, who officiated at public ſacrifices, and were dreſſed with a garment called LIMUS.

LIMNOPEUCE, in *Botany*. See HIPPURIS.

LIMODORUM, in *Botany*. See *Baſtard* HELLEBORE and ORCHIS.

LIMON, in *Botany*. See LEMON.

LIMONIA, in *Botany*, a genus of the *decandria monogynia* claſs. Its characters are that the empalement is divided into five parts; that it has five petals; and that the fruit is a three-celled berry, containing a ſingle ſeed: there is only one ſpecies.

LIMONIUM, in *Botany*. See *Sea*-LAVENDER.

LIMONIUM-*gall*, in *Natural Hiſtory*, the name of a ſpecies of gall or vegetable protuberance, ſerving for the lodging of an inſect, affording a very beautiful appearance on the plant, and very common in the eaſtern parts of the world.

This of the *limonium* is ſingular, in that it is produced from a butterfly egg, and is inhabited by a true caterpillar. The butterfly depoſits her eggs on ſeveral parts of the leaves and ſtalks of this plant, and the young caterpillar, as ſoon as hatched, eats its way through the ſurface; and continuing to eat when within, his depredations occaſion an abundant derivation of juices to the part, by means of which a gall, or protuberance, is formed, which is ſuſtained by a pedicle, and in all reſpects reſembles a fruit. This is of a roundiſh figure, and by degrees grows to the ſize of a nutmeg. It is compoſed of ſeveral coats, or cruſts; the exterior ones are ſoft and ſpungy, but the interior are harder, and more woody than the galls of the oak. As the generality of other caterpillars feed on the ſubſtance of the leaves of trees and plants, this eats only the inſide of its lodgment; and nature ſo readily ſupplies this defect by new matter, that the cavity, in which it is lodged, is never found to be very great.

This ſeems the only known inſtance of a gall formed by a genuine caterpillar; the inhabitants of the willow galls, though uſually eſteemed ſmooth caterpillars, being not ſo, but the worms of a four-winged fly. Reaumur's Hiſt. of Inſects, vol. vi. p. 227.

LIMOSA, in *Ornithology*, the SCOLOPAX *glottis* of Linnæus, the name of a long-legged water-bird, common in Italy, and called by ſome *gutter*, *totanus*, and *pluvialis major*. It is but a ſmall bird, its uſual weight being about ſix or ſeven ounces. Its beak is black, but ſomewhat reddiſh near the angle of the under jaw, which reflects a little upwards; the upper part of its head, neck, ſhoulders, wings, and the forepart of its back, are variegated with brown and grey; the middle of the head-feathers are black, and their ends whitiſh; over each eye paſſes a white line; its rump, and its whole breaſt, belly, and throat, are white; the long wing-feathers are brown; the inner covers of the wings are finely croſſed with double and treble rows of a duſky colour; the tail-feathers are variegated with brown and grey; its legs are very long, and are naked for two inches breadth above the knees. Theſe birds appear on our coaſts, and moſt grounds, in the winter, in ſmall flocks. Ray and Pennant.

LIMOSUS, in *Ichthyology*, a name given by Salvian to the common mackrel, and in his figures to the *thynnus*, or tunny-fiſh, called the *Spaniſh mackrel*.

LIMOSELLA, in *Botany*, *high water plantain*, a name given by Linnæus to a genus of plants of the *didynamia angioſpermia* claſs, called by Dillenius, and others, *plantago aquatica*; the characters of which are theſe: the perianthium is erect, one-leaved, ſlightly divided into five ſegments at the edge, and remaining after the flower is fallen; the flower conſiſts of one petal, which is ſmall, erect, acute, and ſlightly divided into five ſegments at the end; the ſtamina are four erect filaments; the antheræ are ſimple; the germen of the piſtil is oblong and obtuſe; the ſtyle is ſingle, and of the length of the ſtamina, and the ſtigma is globular; the fruit is an oval capſule, affixed to the baſe of the cup, compoſed of two valves, and including

two cells, in which are a great number of small seeds of an oval figure. There is only one species.

LIMPET, *patella*, in *Conchyliology*, the name of a genus of shell-fish, of the *testacea* class of worms in the Linnæan system, the characters of which are these: it is an univalve shell, of a gibbous shape, almoſt conic, without ſpires, always fixed in its natural ſtate to a rock or to ſome hard body, and having its apex or ſummit ſometimes ſharp-pointed, ſometimes obtuſe, ſometimes ſtrait, ſometimes crooked, ſometimes whole, and ſometimes perforated. There are ſeveral ſpecies of each of theſe kinds. See *Tab. of Shells*, N° 1, 2.

The animal inhabiting this ſhell is a ſlug. Linnæus enumerates thirty-ſix different ſpecies.

The Latins call this ſhell *patella* from its reſemblance to a diſh, and the Greeks named it *lepas*, as if they meant to call it a ſcale or flake of the ſtone. Indeed this fiſh always adheres to rocks, as if a part of the ſtone; and the rock ſerves it in the place of a ſecond ſhell, to defend it from the injuries of the weather. Aldrovand and Rondeletius have carried this thought ſo far, as to place the *limpet* among the bivalve ſhells; but no author has followed them in this.

The manner of the *limpet*'s faſtening itſelf to the rocks has not been well underſtood till the time of Mr. Reaumur, though the fact was ſo well known, as to become in ſome places a proverbial compariſon.

The ſhell of the *limpet* approaches to the figure of a cone; the baſe of this cone is occupied by a large muſcle, which alone has nearly as much ſtrength in it as the whole body of the fiſh. This muſcle is not covered by the ſhell, but ſerves the creature equally to move forward, or to fix itſelf by at pleaſure. When it is in a ſtate of reſt, which is the common caſe, it applies this muſcle every way round to the ſurface of ſome ſtone, and holds itſelf by that means fixed very firmly to it, inſomuch that it is impoſſible to take it off with the hands, and thoſe who would remove them are forced to uſe a knife for that purpoſe. and the removing the fiſh this way is not eaſy; for every where that the blade of the knife attempts to enter, the fiſh fixes its muſcle with double force to the ſtone. Mr. Reaumur, to try the force of the adheſion of this fiſh, tied lines with weights at their ends to the ſhells, when placed in a horizontal direction on the ſtone, and found that thirty pounds was the leaſt weight that would tear them off, and that they would reſiſt that for ſeveral minutes. It might be naturally ſuppoſed, that the cauſe of this ſtrong adheſion was the animal's thruſting the fibres of this muſcle into every ſmall pore of the ſtone, and there keeping them forcibly inflated: but were this the caſe, the adheſion muſt ceaſe with the life of the animal: but it does not ſo, for if a *limpet* be cut into ſeveral portions through the ſhell and body, yet every portion, thus ſeparated, will adhere with its due proportion of force to the ſtone. Neither can this force be reſolved on the principles of the adheſion of two poliſhed marbles, or that of leather to ſtone; for in both theſe caſes, whatever perpendicular force the adheſion can bear, the leaſt force applied horizontally makes them ſlip, or ſlide off from one another. But this is not the caſe in the adheſion of this fiſh, it equally reſiſting horizontal and perpendicular force.

The true cauſe of this adheſion is a viſcous juice, a ſort of glue thrown out by this muſcle, which, though imperceptible to the eye, is able to produce theſe great effects. This is eaſily perceived by the touch, however; for if immediately after removing a *limpet* from a ſtone, the finger be applied to the place, it is faſtened very ſtrongly to it by means of the glue left there. If *any* wet, however, have touched the ſtone after the fiſh was removed, there is no viſcoſity perceived on it, the whole ſubſtance of the glue being immediately diſſolved, and its effects wholly taken off by it.

Water is therefore made a ſolvent for this glue; the cloſe adheſion of the outer rim of the great circular muſcle prevents the external water from acting upon it, elſe it muſt always be deſtroyed as ſoon as diſcharged, and ſo be of no uſe; but the under ſurface of the body of the animal is all over covered with ſmall tubercles, containing water, at leaſt many of them do ſo. When the creature then has a mind to unfix itſelf for motion, it only diſcharges a quantity of this water, and the whole cement diſſolves before it, and ſets the creature free. Thoſe tubercles which do not contain water, probably contain the viſcous matter, or glue, whence it may be conveyed by proper veſſels to the circumference; ſo that when the animal has a mind to fix itſelf to a ſtone, it needs only ſqueeze the one ſet of theſe tubercles; and when it would unlooſe itſelf, the other.

This viſcous humidity allotted to this animal, for the fixing itſelf to the rocks, is not peculiar to it; the urtica *marina* has the ſame, and the horns of the *ſea*-URCHINS, by which they fix themſelves, are endued with a power of diſcharging a liquor of the ſame kind, which ſerves them for the ſame purpoſe. Mem. Acad. Par. 1711.

LIMUS, among the Romans, a garment reaching to the ground, and worn by the prieſts, who on that account were called LIMOSINCTI.

LINARIA, in *Botany*. See *Toad* FLAX.

LINARIA, in *Ornithology*. See LINNET.

LINCH-*clout*, in *Artillery*, the flat iron under the ends of the arms of an axle-tree, to ſtrengthen them, and diminiſh the friction of the wheels. See CLOUTS.

LINCH-*pins*. See LYNPINS.

LINCOLNSHIRE *plough*. See PLOUGH.

LINCTUS, a form of medicine, the ſame as LAMBATIVE, *lohock*, and *eclegma*.

LINE, in *Geometry*, a quantity extended in length only, without either breadth or thickneſs.

A *line* is ſuppoſed to be formed by the flux or motion of a point; and is to be conceived as the termination or limit of a ſurface, and not as a part of that ſurface, however ſmall. Hobbes, and ſome others, who have taken it in the latter ſenſe, have fallen into many abſurdities.

There are two kinds of *lines*; viz. *right lines*, and *curve lines*.

If the point A move towards B (*Tab.* III. *Geometry, fig.* 58.) by its motion it deſcribes a *line*; and this, if the point go the neareſt way towards B, will be a right or ſtrait *line*, whoſe definition therefore is the neareſt or ſhorteſt diſtance between any two points, or a *line*, all whoſe points tend the ſame way. If the point go any way about, as in the *lines* ACB, or AeB, it will trace out either a crooked *line*, as the upper AeB; or elſe two or more ſtrait ones, as in the lower AC, CB.

Right lines are all of the ſame ſpecies; but curves are of an infinite number of different ſpecies. We may conceive as many as there are different compound motions, or as many as there may be different ratios between their ordinates and abſciſſes.

Curve lines are uſually divided into *geometrical* and *mechanical*.

LINES, *geometrical*, are thoſe which may be found exactly and ſecurely in all their points. See GEOMETRICAL *line*.

LINES, *mechanical*, are thoſe, ſome or all of whoſe points are not to be found preciſely, but only tentatively or nearly.

Agreeably hereto, Deſcartes and his followers define *geometrical lines* thoſe which may be expreſſed by an algebraic equation of a determinate degree; which equation is alſo called *locus*.

The ſame perſons define *mechanical lines* thoſe which cannot be expreſſed by an equation of a determinate degree.

Others, conſidering that thoſe called by Deſcartes *mechanical lines*, notwithſtanding their not being of a determinate degree, are not leſs preciſe and exact, and conſequently not leſs geometrical than the others; it being this preciſion which conſtitutes the geometricity of the *line*: for this reaſon, they chooſe rather to call thoſe *lines* which are reducible to a determinate degree, *algebraical lines*; and thoſe which are not, *tranſcendental lines*.

Lines are alſo divided into thoſe of the *firſt order*, *ſecond order*, *third order*, &c. See CURVE.

Sir Iſaac Newton enumerated ſeventy-two *lines* of the third order, and Mr. Stirling found four more; ſince that Mr. Stone has found two others, which had eſcaped Sir Iſaac and Mr. Stirling. The two ſpecies added are to be reckoned among the hyperbolico-parabolical curves. Enumer. ſin. Tert. Ordin. Lineæ Tert. Ordin. Newtonianæ Oxon. 1717. 8vo. Phil. Tranſ. N° 450. § 6. See CURVE.

Lines, conſidered as to their poſitions, are either *parallel*, *perpendicular*, or *oblique*; the conſtruction and properties of each whereof, ſee under PARALLEL, PERPENDICULAR, &c.

Euclid's ſecond book treats muſtly of *lines*, and of the effects of them being divided, and again multiplied into one another.

LINES, *algebraic*, are divided into different orders, according to the degree of their equations. Theſe degrees are eſtimated, as in determined equations, by the degree of the higheſt term of the equation.

Thus $a+by+cx=0$, is a general equation, expreſſing the nature of *lines* of the firſt order, or of ſtrait *lines*.

The equation $a+by+cx+dyy+exy+fxx=0$, repreſents the *lines* of the ſecond order; that is, the conic ſections, and the circle, which is one of them.

And the equation $a+by+cx+dyy+exy+fxx+gy^3+hyyx+ixy^3+kx^3=0$, expreſſes in general the *lines* of the third order. And the *lines* of the fourth and higher orders may be expreſſed in the like manner. See Cramer, Introd. à l'Analyſe des Lignes Courbes, p. 52, ſeq.

Mr. Cramer uſes the terms, *line* of the ſecond, third, fourth,

fourth, &c. order, and *curve* of the second, third, fourth, &c. order, indifferently. Sir Isaac Newton has made a diſtinction, according to him. See CURVE.

LINES, *circular, converging, diverging, generating, heliſpherical, hyperbolic, logiſtic, magnetical, normal, proportional, quadratures, reciprocal, reflexion,* and *vertical.* See the reſpective adjectives.

LINE *of the apſides*, in *Aſtronomy*, is the *line* which joins the APSIDES; or it is the greater axis of the orbit of a planet.

LINE, *fiducial*, the *line* or ruler which paſſes through the middle of an aſtrolabe, or the like inſtrument; and on which the ſights are fitted; otherwiſe called *alhidade, index, dioptra*, and *mediolineum*.

LINE, *horizontal*, a *line* parallel to the HORIZON.

LINES, *ſolſtitial* and *meridian*. See the adjectives.

LINE *of the nodes*, in *Aſtronomy*, is the *line* which joins the NODES of the orbit of a planet, or the common ſection of the plane of the orbit with the plane of the ecliptic.

LINE, *horizontal*, in *Dialling*, is the common ſection of the horizon, and the dial-plane.

LINES, *horary*, or *hour-lines*, are the common interſections of the hour-circles of the ſphere, with the plane of the dial. See HORARY, and HOUR-*circles*.

LINE, *ſubſtylar*. See SUBSTYLAR.

LINE, *equinoctial*, in *Dialling*, is the common interſection of the equinoctial, and the plane of the dial.

LINE, *contingent*. See CONTINGENT.

LINES, *dialling*, and *meridian*. See the reſpective adjectives.

LINE, in *Fencing*, is that part of the body directly oppoſite to the enemy, wherein the ſhoulders, the right arm, and the ſword, ought always to be found; and wherein are alſo to be placed the two feet, at the diſtance of eighteen inches from each other.

In this ſenſe, a man is ſaid to be in his *line*, to go out of his *line*, &c.

LINE, in *Fortification*, is ſometimes taken for a ditch, bordered with its parapet; and ſometimes for a row of gabions, or ſacks of earth, extended lengthwiſe on the ground, to ſerve as a ſhelter againſt the enemies fire.

When the trenches were carried on within thirty paces of the glacis, they drew two *lines*, one on the right, and the other on the left, for a place of arms.

For the difference between trenches or approaches, and *lines*, ſee INTRENCHMENT.

Lines are generally made to ſhut up an avenue or entrance to ſome place; the ſides of that entrance being covered by rivers, woods, mountains, moraſſes, or other obſtructions, not eaſy to be paſſed over by an army. When they are conſtructed in an open country, they are carried round the place to be defended, and reſemble the *lines* ſurrounding a camp, called *lines* of circumvallation. *Lines* are likewiſe thrown up to ſtop the progreſs of an army; but the term is moſt commonly applied to the *line* which covers a paſs that can only be attacked in front. For conſtructing ſuch a *line*, in the place moſt convenient for the purpoſe, let a rope be run quite acroſs the way along the intended place of the *line*, pegging it to the ground at the diſtance of every four or five yards; and at the diſtance of about ten or twelve feet before the *line*, towards the enemy, let ſuch another *line* or row of ſtakes be carried in a poſition parallel to the firſt rope. When the labourers are properly ranged within theſe limits, let them dig up the earth in this breadth, and throw it on the other ſide of the firſt rope, until a bank of about five or ſix feet thick, and fit or ſeven feet high, be raiſed, ſloping the ſides according to the declivity neceſſary for the earth's rolling naturally down the bank; and let the digging be continued till the ditch is about five or ſix feet deep, the breadth of the bottom being about one-third of the breadth ſtaked out at top; the bank may be rendered more firm by being trod or rammed down. Let the inner ſide of the bank be pared with the ſpade into ſuch a ſlope, as a man ſtanding upright may eaſily touch, with his arm extended ſtrait before him; and at the foot of this bank, let a foot-bank or ſtep be raiſed, of ſuch a height, as a man ſtanding on it may eaſily fire his muſket over the bank, or let it be about four feet and a half lower than the top of the bank or breaſt-work. A gentle ſlope may alſo be made to the foot-bank, that the troops may more eaſily aſcend it; and let the crown or top of the breaſt-work be ſloped ſo, that a muſket laid flat on it may ſtrike the ground with its ſhot, about five or ſix feet beyond the ditch. The bank or breaſt-work will, in this caſe, ſecure the troops behind the *line* from the enemy's fire; and when they ſtand on the foot-bank, they are more than two-thirds covered, and, conſequently, the troops within may make three of their ſhots tell for one of the enemy; and by going off the foot-bank, they may be quite covered, while they load again; ſo that with this advantage, they are in no great danger of being forced from the *lines*, unleſs the enemy are greatly ſuperior in number and cannon.

The following table ſhews the dimenſions of *lines* commonly conſtructed, and the rate of expence attending the conſtruction of them.

Breaſt-work			Ditch			Expence	
Thickness at top	Height within	Height without	Upper breadth	Lower breadth	Depth	Solid content	Days works
Feet	Feet	Feet	Feet	Feet	Feet	Feet	
4	7½	6	8	2⅞	5	45	1
5	7½	6	10	3½	5½	65	1½
6	7½	6	12	4	6	88	2
7	7½	6	14	4½	6½	110	2½
8	7½	6	16	5½	7	132	3
9	7½	6	18	6	7½	155	3½

The day's work here is for one yard in length; and in the firſt, a hundred men will complete a hundred yards in length of this kind of *lines* in one day; two hundred men in half a day, &c. The *lines* above deſcribed are called temporary *lines*, and chiefly ſerve a preſent emergency. When *lines* are thrown up at leiſure, and deſigned for longer duration, then the ditch is uſually eighteen feet broad at top, ſeven or eight feet deep, and the ſides of the ditch are ſloped, ſo as to leave only ſix feet breadth at bottom; the breaſt-work, or parapet, is about ſeven feet thick on the top or crown, and ſeven or eight feet high. The heights, depths, and breadths, of the ſeveral parts of a *line* well deſigned and finiſhed, are exhibited in *Tab.* VII. *Fortification, fig.* 44. in which LL repreſents the ground *line*, or ſurface of the place; AB the breadth of the ditch at the top; CD its breadth at the bottom; FAC the ſlope or ſcarp of the parapet and ditch; DBK the counterſcarp; EF the top or crown of the parapet or breaſt-work; EG the inner ſlope of the parapet; HG the top of the foot-bank; HI the ſlope of the foot-bank; and BKL a ſmall ſloping bank, called the glacis. This ſection or profile may be drawn, by laying off in the ground-*line*, from any ſcale of equal parts, the diſtances $1a = 6$ feet, $ab = 1\frac{1}{2}$, $cd = 7$, $dA = 4\frac{1}{2}$, $Af = 6$, $fg = 6$, $gB = 6$, and $BL = 5$ feet. Through a, b, c, d, e, f, g, B, draw lines perpendicular to IL. Make $aH = 2\frac{1}{2}$ feet $= bG$, $cI = 7$ feet, $dF = 6$, $fC = 8$ feet $= gD$. Draw IH, HG, GE, EF, FAC, CD, and DB, which continue, till it meets the line FL, and the profile is conſtructed.

When *lines* are made to cover a camp, or a large traſt of land, where a conſiderable body of troops is poſted, the work is not made in one ſtrait, or uniformly bending *line*; but at certain diſtances, the *lines* project in ſaliant angles, called redents, reduits, or flankers, towards the enemy. The diſtance between theſe angles is uſually between the limits of two hundred and two hundred and ſixty yards; the ordinary flight of a muſket-ball, point-blank, being generally within thoſe limits; although muſkets, a little elevated, will do effectual ſervice at the diſtance of three hundred and ſixty yards. In *Tab.* VII. *Fortification, fig.* 45. are ſhewn the forms of the uſual *lines*, where the figures CAB, *cab*, are the redents or flankers; AC, AB, *ac*, *ab*, the faces; CB, *cb*, the gorges; AD, *ad*, the capitals; B*b* the curtin; and the angles CAB, *cab*, the ſaliant or flanked angles. The diſtance of the ſaliant angles is about two hundred and forty yards at a mean; the length of the capital is uſually between forty and fifty yards, and the length of the gorges is alſo about ſixty or ſeventy yards.

To make a plan of *lines* with redents: draw the *line* EEEE, &c. *Tab.* VII. *Fort. fig.* 46. in ſuch a manner, that, wherever theſe is a bend or angle, it may be either at once, twice, or thrice, &c. the length of about two hundred and forty yards from one another; ſo that there may be a redent where there is an angle. In this *line*, lay off the diſtance of two hundred and forty yards from E to E, E to E, &c. reckoning from the bends towards each end, whether it happens that the *line* will or will not be exactly meaſured by a repetition of the two hundred and forty yards. At each point, E, draw the capital EF in a perpendicular poſition to the direction of the *line* in that point, and make the capitals about forty or fifty yards long. On each ſide of E, take the half gorges EG, EG, each of about thirty or thirty-five yards, and draw the faces FG, FG; and thus the outline or maſter-line of the curtins and redents is formed. Parallel to each curtin and face draw *lines*, within, at the diſtances from the maſter-line of ſeven feet, eight feet, twelve feet, and eighteen feet; then the breadth of ſeven feet repreſents the plan of the parapet, that of one foot its inner ſlope, that of four feet the top of the foot-bank, and

and that of six feet the foot-bank slope. On the outside of the master-line, draw *lines* at the distances of 10½, 16½, and 22½ feet, parallel to each curtin and face; and these will represent the plans of the scarp, ditch, and counterscarp; observing that the saliant angles of the counterscarp are rounded before the angles of the redents. A plan of this kind formed from a small scale, as of twenty yards to an inch, is usually represented by four parallel *lines*; one without the master-line representing the counterscarp or out-line of the ditch, and two within, representing the breadths of the parapet and foot-bank. In some cases a short *line* is hastily formed by a number of CHEVAUX *de frise* chained together; and in countries abounding with wood, a *line* may be formed by laying, in a position pointing to the enemy, the stems of trees and their larger branches, piled on one another to a sufficient height, and the interstices filled with earth: such a work is called an ABBATIS. See Robertson's Marine Fort. p. 2, &c.

LINE, *fundamental*, is the first *line* drawn for the plan of a place, and which shews its area.

LINE, *capital*, in *Fortification*. See CAPITAL.

LINE, *central*, is that drawn from the angle of the center, to that of the bastion.

LINE *of defence*. See DEFENCE.

LINE *of defence flehant*. See DEFENCE.

LINE *of defence rasant*. See DEFENCE.

LINE *of approach*, or *attack*, signifies the work which the besiegers carry on under cover, to gain the moat, and the body of the place. See APPROACHES.

LINE *of counter-approach*. See COUNTER-*approach*. See *Tab.* VII. *Fortification, fig.* 33.

LINE *of circumvallation*, is a *line* or trench cut by the besiegers, within cannon-shot of the place, which ranges round their camp, and secures its quarters against any relief to be brought to the besieged. See CIRCUMVALLATION.

LINE *of contravallation*, is a ditch bordered with a parapet, which serves to cover the besiegers on the side of the place, and to stop the sallies of the garrison. See CONTRAVALLATION.

LINES *of communication*, are those which run from one work to another. See *Tab. Fortif. fig.* 21. *n.* 2. 2, &c. See also COMMUNICATION. But

The LINE *of communicating*, more especially so called, is a continued trench, with which a circumvallation, or contravallation, is surrounded; and which maintains a communication with all its forts, redoubts, and tenailles.

LINE *of the base*, is a right *line*, which joins the points of the two nearest bastions.

To LINE a *work*, signifies to face it, chiefly with brick or stone; e. gr. to strengthen a rampart with a firm wall, or to encompass a parapet or moat with good turf, &c.

LINE, *indented*, in *Fortification*. See REDENT.

LINES, among *Fowlers*, is used to express the strings by which they catch birds. The large and small land birds are equally easy to be taken by them, and sometimes the water-fowl.

These *lines* are made of long and small cords, knotted in different places, and containing in length as many fathom as the places where they are to be laid require. Plovers, and the larger wild fowl, are very conveniently taken by them. When these strings are to be used, they must be limed with the strongest bird-lime that can be got, and then coming to their haunts before the evening flights, that is before sun-set; or, for the morning flights, at least two hours before day, the sportsman is to carry a parcel of small sticks, each about two foot long, and sharpened at both ends, but having a little slit in one end like a fork. The plain end of each stick is to be stuck into the ground, in such a manner, that the stick standing aslant, its upper or forked end may be about a foot and a half from the surface. The limed strings are then to be carried along all these sticks, in different rows, some higher than others. Every row of the sticks is thus to be filled, and the whole haunt covered with the *lines*. The plover, and other birds that fly low, when they come to their haunts, fly directly in among these strings, and are taken in great numbers; the whole flight coming in at once, and covering all the place, so that those which are not yet alighted, have no opportunity of seeing the distress of their companions. There is no need for the sportsman to be constantly upon the watch for the taking of the birds; for when once they are taken they cannot loosen themselves, so that he may come and take them up at his own time. The water-fowl may be easily taken, in the same manner, by observing their haunts, and stretching these *lines*, in several rows, across the brook, or river, some higher and some lower, the lowest lying almost at the edge of the water. These must never be used in moon-light nights on the occasion; for the shadow of the strings in the water will then fright them away.

LINE, in *Genealogy*, is a series or succession of relations in various degrees, all descending from the same common father.

LINE, *direct*, is that which goes from father to son; which is the order of ascendants and descendants. See DIRECT.

LINE, *collateral*, is the order of those who descend from some common father related to the former, but out of the *line* of ascendants and descendants. In this are placed uncles, aunts, cousins, nephews, &c. See COLLATERAL.

LINE, in *Geography* and *Navigation*, is used, by way of eminence, for the EQUATOR, or EQUINOCTIAL *line*.

The *line* in the heavens is a circle described by the sun in his course on the 20th day of March, and the 23d of September. The *line* on the earth is an imaginary circle, answering to that in the heavens. It divides the earth, from east to west, into two equal parts, and is at an equal distance from the two poles; so that those who live under the *line*, have the poles always in their horizon.

The latitudes commence from the *line*.

The seamen use to christen their fresh men, and passengers, the first time they cross the *line*. See BAPTISM.

LINES, in *Heraldry*, the figures used in armories to divide the shield into different parts, and to compose different figures.

They are of different forms, and were it not for this, many arms would be one and the same, for a chief wavey differs from a plain chief, by the *lines* which compose them, and the heralds shew particular reasons for all these different forms of *lines*.

These *lines*, according to their forms and names, give denomination to the pieces or figures which they form, except the strait or plain *lines*, which are carried evenly through the escutcheon, and are four, *viz.* the perpendicular *line*, the horizontal, the diagonal *line* dexter, and the diagonal *line* sinister.

The crooked *lines*, which are carried unevenly through the escutcheon, rising and falling, are these: first the ingrailed or ENGRAILED, and inverted or INVECTED; these when represented together are somewhat known the one from the other, being opposite to one another, both being made, as it were of semi-circles. The ingrailed with the points upward, the invected with the points downward. But this is not a sufficient distinction; for suppose the space between them which they form be a fess, then the whole is only ingrailed, not invected; for the fess ingrailed must have the points on both sides turned toward the field, and the convex or gibbose parts toward the fess itself, and so of a bend, chevron, and other proper figures of heraldry; and if these be invected, then the convex parts of the *lines* are toward the field: but these *lines* are better distinguished when placed by way of bordure, with the letters within a bordure ingrailed or invected.

These two *lines* are more hard to be distinguished, when the field is divided into two equal parts, of different colours, as parted per pale, parted per fess, &c. Here we know not whether the *line* be ingrailed or invected, except we follow this rule, that the form of the *line* must be applied to the colour first named. The French terms for these two *lines* are for the ingrailed, *engrele*, and for the invected, *comole*; and the Latin writers express ingrailed by *ingredians, imbricatus*, and *striatus*, and the invected by the words *invertus* and *canaliculatus*.

The wavy, or WAVED *line*, is such an one as is formed in representation of the waves of the sea, as parted per fess wavy in arms and other waved *lines*, as the wavy bars all express that the person got his honours by sea service. Nebulee is another name of a *line* in heraldry; it expresses a clouded *line*, the French call it *nuancee*, and the Latins *nebuloffe lines*; this also has been given to persons, who have been eminently skilled in navigation.

Crenele, or EMBATTLED *line*, represent the battlements of a house, and are said to represent in heraldry the skill in architecture, for which the first of the family was famous; they were also given sometimes for eminent services, in assaulting or defending castles in time of war, and sometimes only as emblems of a house, to express a person who bare them, being of a noble house or family; for of old none were suffered to embattle their houses but persons of great distinction.

The Latin writers in heraldry use for the word *crenele*, the terms *pinnatus* and *pinnis asperatus*, according to Ursus in his blazons, and Sylvester Petra Sancta in his *mirakes pinnules*.

There is another *line* of this kind in heraldry, which Leigh calls the battled embattled *line*; this has one degree of embattling above another. When the upper points in this kind of *line* are represented sharp, it is called campagne, as if the *lines* ending in points, represented bastions, or the outer works of cities and camps;

and

and when the upper points are rounded, it is called crenele embattled arrondi.

The INDENTED *line* is notched so at the edges that it represents the teeth of a saw, and has its name from the Latin *dens*, a tooth; or from the law term *indenture*, a sort of deed, the top of which is always notched like the teeth of a saw.

The dancette is another *line*, very much resembling the indented *line*, but that it is always much smaller; it is therefore said by the heralds to be the same in quality but not in quantity. The dancette differs also from the indented *line*, in that it always consists but of a few teeth, though never less than three, according to Mr. Holmes, in his Office of Armory; whereas the indented *line* has always a great many teeth. The French express our indented *line* by the terms *danche* or *dentille*; and the dancette, when it has but very few teeth, and those very long, by the term *vivree*, which Menestrier takes to be the letter M, with its legs extended from side to side of the shield, because many who carry a partition, or sess, after that form, have the family name, beginning with that letter. The Latin writers express the term indented, by *dentatus*, *indentatus*, and *denticulatus*, and when the teeth are very long, as in the dancette, they call them *dentes decussati*. See also NEBULY and RAGULED.

There are yet two other *lines* mentioned by the heraldry writers; the first is the PATRE or DOVETAIL *line*, so called from its resemblance to a sort of joint used by our carpenters, in which one part goes alternately all the way down between two others; this is called by Morgan the linchet, or labelled line, because the points as they proceed from the ordinary, such as the chief or sess, represent not unlike the points, or rather the ends of labels. The other *line* is called URDE or *champagne* by Fresne; and by Upton, *vair*, because its points are formed like pieces of the fur called by heralds *vair*.

The two last of these are in very little use, the others are the common *lines* of arms, and are called the attributes or accidents of armorial figures which they form; and if any other *lines* are found in the figures or engravings of arms, which are not reducible to the one or the other of these, they are called *irregular*, and by the French heralds *elatte*. The knowledge and use of these forms of *lines* are necessary in the science of heraldry, to distinguish and difference many armorial bearings.

LINE, *labelled*. See LABELLED.

LINE, *lateral*, *linea lateralis*, in *Ichthyology*, a name given by naturalists to a *line* or streak, with which many kinds of fish are marked, passing along their sides. Few fish are without this *line*; but it is very variously formed in the several kinds, and makes a very considerable article in their description, if not in the distinction of the species. In some species it is made of a series of little points, or holes, as appears to the eye: of this nature is the *line* in eels, &c. In some others it is formed of a sort of duct, running along the center of a great number of scales. This is its structure in the generality of fishes. This *line*, in various kinds of fish, varies also in regard to number, situation, figure, and other properties. In regard to number, there is no *line* observed in the syngnathi and petromyzon, in almost all other fish, there is one on each side; and, finally, in some there are as it were two *lines* on each side: an instance of this we have in the ammodytæ. In regard to the situation, the differences are these. 1. In some it is near the back, as in the clupea, salmons, perch, and the like. 2. In others it is placed nearer the belly, and runs parallel with it, as in the cyprini. 3. In some it is placed in the center of each side between the back and the belly, as in the carassius. 4. In some it is placed against the interstices of the muscles, or the spina dorsalis, as in the murænæ. And, 5. In some it is placed above the interstices, as in the ammodytæ, &c. It has been supposed, by many, that this *linea lateralis* was always parallel to the interstices of the muscles, but this is evinced to be an erroneous opinion, by the observation of the pearch and mackrel. In regard to the differences of figure, this *line* is in some straight, as in the coregone, salmons, &c. 2. In others it is crooked, as in the cyprini, the gwarch, &c. and in the generality of fish is smooth to the touch, but in some it is rough and aculeated, as in the trachurus and pleuronectæ.

LINE *of the banquet*, in the *Manege*. See BANQUET.

LINE *of a volt*, in the *Manege*. See SQUARE and VOLT.

LINE *of direction*, in *Mechanics* and *Gunnery*. See DIRECTION.

LINE *of gravitation of a heavy body*, is a *line* drawn through its center of gravity, and according to which it tends downwards.

LINE *of the first act of descent of a heavy body*. See DESCENT and CYCLOID.

LINE *of a projectile*. See PROJECTILE.

LINES, in *Music*, are used for those strokes drawn horizontally on a piece of paper, on and between which the characters and notes of music are disposed. Their number is commonly five; when another is added for one, two, or more notes, it is called a LEGER-*line*.

Some say that it is to Guido Aretine that we owe their invention: they are very commodious, and greatly assist the imagination in distinguishing the low notes from the high. Upon their first introduction, the *lines* only were used, and the spaces between them entirely neglected.

Originally there were as many *lines* drawn for a song, as it required notes ascending; but at length the notes being placed in the intervals of the *lines*, these were reduced to four; so that there were nine places or degrees for nine different sounds, which was their extent: at last they raised the number to five, of which the lowest is reckoned first; and hereon they placed the characters for eleven different sounds, including the spaces above the fifth and below the first; and at the same time they had the liberty, at pleasure, to add more *lines*, if the song ran to a greater compass.

LINE, *geometrical*, in *Perspective*, is a right *line* drawn in any manner on the geometrical plane.

LINE, *horizontal*. See HORIZONTAL.

LINE, *terrestrial*, or *fundamental line*, in *Perspective*, is a right *line*, wherein the geometrical plane, and that of the picture, or draught, intersect one another.

Such is the *line* NI (*Tab. Perspective*, *fig.* 12.) formed by the interiection of the geometrical plane LNI, and the perspective plane, HI.

LINE *of the front*, in *Perspective*, is any right *line* parallel to the terrestrial *line*.

LINE, *vertical*, is the common section of the vertical, and of the draught.

LINE, *visual*, is the *line*, or ray, imagined to pass from the object to the eye.

LINE *of station*, in *Perspective*, according to some writers, is the common section of the vertical and geometrical planes. Others mean by it, the perpendicular height of the eye above the geometrical plane; others, a *line* drawn on that plane, and perpendicular to the *line* expressing the height of the eye.

LINE, *objective*, in *Perspective*, is any *line* drawn on the geometrical plane, whose representation is sought for in the draught or picture.

LINE *of distance*. See DISTANCE.

LINES *on the plain scale*, in *Trigonometry*, are the *line* of chords, *line* of sines, *line* of tangents, *line* of secants, *line* of semi-tangents, *line* of leagues. The construction and application whereof, see under SCALE, SAILING, &c.

LINES *on Gunter's scale*, are the *line* of numbers, *line* of artificial sines, *line* of artificial tangents, *line* of artificial versed sines, *line* of artificial sines of rhumbs, *line* of artificial tangents of the meridian *line*, and *line* of equal parts. The construction and application whereof, see under GUNTER'S *scale*.

LINES *of the sector*, are the *line* of equal parts, or *line* of *lines*; *line* of chords, *line* of sines, *line* of tangents, *line* of secants, *line* of polygons, *line* of numbers, *line* of hours, *line* of latitudes, *line* of meridians, *line* of metals, *line* of solids, *line* of planes; the construction and use whereof, see under SECTOR.

LINE, in the *Art of War*, is understood of the disposition of an army, ranged in order of battle; with the front extended as far as may be, that it may not be flanked.

An army usually consists of three *lines*; the *first* is the front, van, or advance-guard; the main body forms the *second*, in which is the general's post; the *third* is a reserved body, or rear-guard.

The second *line* should be about three hundred paces behind the first, and the reserve at about five or six hundred paces behind the second.

The artillery is likewise distributed along the front of the first *line*. The front *line* should be stronger than the second, that its shock may be more violent, and that, by having a greater front, it may more easily close on the enemy's flanks. See ARMY.

LINE, *to break the*, is to change the direction from that of a strait *line*, in order to obtain a cross-fire.

LINE, *turning out of the*. The *line* turns out without arms whenever the general commanding in chief comes along the front of the camp. When the *lines* turn out, the private men are drawn up in a *line* with the bells-of-arms; the corporals on the right and left of their respective companies; the picquet forms behind the colours, with their accoutrements on, but without arms. The serjeants draw up one pace in the front of the men, dividing themselves equally. The officers draw up in ranks according to their commissions, in the front of the colours; two ensigns taking hold of the colours. The field-

field-officers advance before the captains. The camp-colours on the flanks of the parade are to be struck, and planted opposite to the bells-of-arms; the officers ſpontoons are to be placed between the colours, and the drums piled up behind them; the halberts are to be planted between and on each ſide the bells-of-arms, and the hatches turned from the colours. Milit. Dict.

LINE, or LINE *of battle*, is alſo applied to the diſpoſition of a fleet on the day of ENGAGEMENT; on which occaſion the veſſels are uſually drawn up, as much as poſſible, *in a ſtrait line*, as well to gain and keep the advantage of the wind, as to run the ſame board.

This right *line*, or long file, is prolonged from the keel of the hindmoſt to that of the foremoſt, and paſſes longitudinally through the keels of all the others, from the van to the rear; ſo that they are, according to the ſea-phraſe, in the wake of each other. In the *line*, or order of battle, all the ſhips of which it is compoſed are cloſe-hauled, upon the ſtarboard or larboard tack, about fifty fathoms diſtant from each other. When a fleet is drawn up in *line*, in preſence of an enemy, it ſhould be formed in ſuch a manner as that the ſhips may mutually ſuſtain and reinforce each other, and yet preſerve a ſufficient ſpace in their ſtations, to work or direct their movements with facility during the action. The *line* cloſe-hauled is peculiarly choſen at the order of battle, becauſe if the fleet, which is to windward, were arranged in any other *line*, the enemy might ſoon gain the weather-gage of it; and even if he ſhunks it expedient to decline that advantage, it will yet be in his power to determine the diſtance between the adverſe fleets, in an engagement, and to compel the other to action. The fleet to lee-ward, being in a *line* cloſe-hauled, parallel to the enemy, can more readily avail itſelf of a change of the wind, or of the neglect of its adverſary, ſo as to get to windward of him; or, at leaſt, ſo as to avoid coming to action, if the enemy is much ſuperior, or to prevent him from eſcaping, if he ſhould attempt it. Beſides, in this order, the ſails of each ſhip are ſo diſpoſed as to counteract each other, and, therefore, the ſhips in general neither advance nor retreat during the action, and are thus enabled to keep their ſtations, and to proſecute the battle with vigour, and without diſorder. Whilſt the uniformity of the *line* is preſerved, the admiral's orders may be readily communicated by ſignals from the van to the rear; diſtreſſed ſhips may be more eaſily diſcovered and relieved, and the ſituation and circumſtances of the enemy's *line* will be open to the view of the commander in chief. Moreover, the ſhips of the *line* ſhould not only be ſufficiently cloſe to ſuſtain each other, but they ſhould be of the larger ſort, with the weighteſt metal. Many advantages concur to recommend the larger ſhips in a *line* of battle; they overlook thoſe of an inferior rate, which are accordingly laid open to the fire of their muſquetry. In a high ſea they can more ſafely employ the artillery of their lower deck than a ſmaller ſhip; and if both are obliged to ſhut their lower deck-ports, the advantage of the three-decked ſhips, with regard to their cannon, will yet be conſiderable; they have three tier againſt two, and two againſt one. The ſame ſuperiority ſubſiſts, in caſe they are diſmaſted, when the upper deck is encumbered with the ruins: the large ſhip being higher between decks, are leſs incommoded with the ſmoke, and their cannon is managed with greater facility; the large ſhips, having greater ſolidity of frame, are better calculated to reſiſt the effects of battle and tempeſt. In general alſo they ſail better than the ſmall ones, except in fine weather, or in a freſh wind, when the ſea becomes agitated, they have always the ſuperiority. The fire-ſhips do not ſucceed ſo well againſt large ſhips as the ſmaller ones; the artillery will ſink them, or oblige them ſooner to relinquiſh their deſign, and they are eaſily towed away by the great long-boats. The *line* of a fleet, which has many capital ſhips, need not be ſo much incloſed as that of an enemy, which has fewer. The former may be alſo leſs numerous, without being weaker. This circumſtance, however, ſhould not exclude a certain number of the third and fourth rates, which are neceſſary in all naval armaments.

The weather-*line* and the *line* to leeward have their ſeveral advantages and inconveniences. The chief advantages of the former are, that it may approach the enemy, ſo as to determine the time and diſtance of the action: if it is more numerous than the lee-*line*, it may eaſily appoint a detachment to fall upon the van and rear of the latter, and incloſe it between two fires. It is little incommoded by the fire or ſmoke of the cannon, and may diſpatch the fire-ſhips, under cover of the ſmoke, upon the diſabled ſhips of the lee-*line*, or ſo as to oblige the enemy to break the *line*, and bear away. But the weather-*line* has alſo its defects; when the ſea is rough, and the wind boiſterous, it cannot readily fight with the lower deck battery: it cannot decline the action, without the dangerous expedient of forcing through the enemy's *line*; and if it keeps the wind, the lee-*line* may incloſe and totally deſtroy it. The diſabled ſhips of the weather-*line* muſt tack, to avoid falling into the enemy's fleet; and if they are much ſhattered, they may be altogether ſeparated from their own fleet, particularly if they are in the rear of the *line*.

The advantages of the *line* to lee-ward are theſe: the ſhips of the former may uſe the guns of their lower decks, without the hazard of taking in much water at the ports in ſtormy weather, which the *line* to windward cannot do without great danger. The lee-*line*, though it cannot ſo eaſily double upon the van and rear of the enemy, and incloſe them between two fires, may nevertheleſs have opportunities of tacking, and cutting off a part of the enemy's rear. The diſabled ſhips to lee-ward are more eaſily removed from the fire than thoſe to windward; and the lee-*line* can with greater facility avoid the action than its adverſary, which is a circumſtance very favourable to an inferior ſquadron. But the defects of the lee-*line* are, that it cannot decide the time and diſtance of the battle, which may commence before it is ſufficiently formed; and it will perhaps be attacked by an enemy bearing down upon it in regular order. The fire and ſmoke of the weather-*line* are a great inconvenience to it; and it cannot eaſily break the enemy's *line* with its fire-ſhips, which are very ſlowly and with great difficulty conveyed to windward. The admiral's ſhip always preſerves her ſtation in the center of the *line*. The *line* is ſaid to be formed a-breaſt, when the ſhips ſides are all parallel to each other, *on a line* which croſſes their keels at right angles. This is moſt frequently uſed in purſuing or retreating, with the wind right-aft, ſo that the *line* forms a perpendicular with the direction of the wind. Falconer's Mar. Dict.

LINE is alſo a name given to ſeveral ſmall cords, of different ſizes, and uſed for various purpoſes at ſea.

LINE, *ſhip of the*, is a veſſel large enough to be drawn up in the *line*, and to have a place in a ſea-fight. See SHIP.

LINE, *knave*, in a ſhip. See KNAVE.

LINE *of meaſures*, is uſed by Oughtred to denote the diameter of the primitive circle in the projection of the ſphere in plano, or that *line* in which the diameter of any circle to be projected *falls*.

In the ſame ſenſe, the projection of the ſphere in plano, the *line of meaſures* is that *line* in which the plane of a great circle, perpendicular to the plane of the projection, and that oblique circle which is to be projected, interſects the plane of the projection; or it is the common ſection of a plane, paſſing through the eye-point, and the center of the primitive; and at right angles to any oblique circle, which is to be projected, and in which the center and pole of ſuch circle will be found.

LINE, *meaſure of a*. See MEASURE.

LINE *of demarcation*, or *alexander-an line*, is a meridian paſſing over the mouth of the river Maragnon, and by the capes of Hommas and Malabrigo; ſo called from pope Alexander VI. who, to end the diſputes between the crowns of Caſtile and Portugal about their boundaries, in 1493, drew an imaginary *line* on the globe, which was to terminate the pretenſions of each. By which partition, the Eaſt Indies fell to the lot of the Portugueſe; and the Weſt Indies, then newly diſcovered, to the Caſtilians.

LINE, *braiding, lunt, cravat, ſwabber, leg, thumb*, and *water*, ſee under the reſpective adjectives.

LINE alſo denotes a ſmall French meaſure, containing the 12th part of an inch, or 144th part of a foot.

The geometricians, notwithſtanding its ſmallneſs, conceive the *line* ſubdivided into 12 points.

The French *line* anſwers to the Engliſh *barley-corn*.

LINES, *nooſing*. The beſt materials for making theſe *lines* are *fine* and even horſe-hairs: the hair ſhould be round and twiſted even, for that greatly ſtrengthens it; and all the hairs ſhould be of an equal bigneſs, or as nearly ſo as may be. They ſhould be laid in the water about a quarter of an hour after twiſting, that it may be ſeen which will ſhrink; they are then to be twiſted over again. In this laſt twiſting ſome intermingle ſilk among them, but that is not to well. *Lines* made entirely of ſilk are not bad; but thoſe of ſilk and hair mixed are never found to do well. The beſt colours for a *line* are ſorrel, white, and grey; the two laſt are beſt for angling in clear waters; the former in muddy ones. The pale watery-green is alſo a very good colour, and may be made thus: boil in a quart of alum-water a large handful of marygold-flowers; there will ariſe a ſcum, which muſt be taken off; then add to this liquor copperas and verdigris, of each half a pound, beat to powder together; boil theſe up together; then put the hair into this liquor, and let

it lie ten or twelve hours; it will obtain a watery bluish green colour, which will not wash out afterwards.

LINE *of equated bodies*. See EQUATED *bodies*.

LINES, *gangs*, *plats*, and *rows*. See the several adjectives.

LINE, *white*, in *Printing*. See WHITE.

LINEA *alba*, in *Anatomy*, the concourse of the tendons of the oblique and transverse muscles of the abdomen; dividing the abdomen in two, in the middle.

It is called *linea*, *line*, as being ſtrait; and *alba*, from its colour, which is white.

The *linea alba* receives a twig of a nerve from the intercostals in each of its digitations or indentings, which are visible to the eye, in lean persons especially.

LINEA *medianа*. See MEDIANA.

LINEA *nubeculosa*. See NUBECULOSA *linea*.

LINEAL *descent*. See DESCENT.

LINEAL *exegesis*. See EXEGESIS.

LINEAMENT, a fine ſtroke or line obſerved in the face, and forming the delicacy thereof; being that which preſerves the reſemblance, and occaſions the relation of likeneſs, or unlikeneſs, to any other face.

It is by theſe that phyſiognomiſts pretend to judge of the temper and manners of people.

LINEAMENT is alſo uſed by the painters for the outline of a face. See CONTOUR.

LINEANS *punctum*. See PUNCTUM.

LINEAR *book*. See LEAF.

LINEAR *problem*, in *Mathematics*, is that which may be ſolved geometrically, by the interſection of two right lines. E. gr. To meaſure an inacceſſible height by the means of two unequal ſticks, &c.

This is alſo called a *ſimple* PROBLEM, and is capable but of one ſolution.

LINEAR *numbers*, are ſuch as have relation to length only. See NUMBER.

Such, e. gr. is a number which repreſents one ſide of a plane figure. If the plane figure be a ſquare, the *linear number* is called a *root*.

LINEATORES, in the Hippodrome at Conſtantinople, were the ſame with the *deſignatores* in the Circus at Rome. See HIPPODROMUS, CIRCUS, DESIGNATOR.

LINEN. There are various ſorts of *linen*, the principal materials of which are cotton, flax, and hemp. The *linen* trade of Europe is chiefly in the hands of the Ruſſians, Germans, Swiſs, Flemings, Hollanders, and French.

Linen is the ſtaple of Scotland; but it was long neglected. The Scots at preſent are not, however, in ſo bad a ſituation in reſpect to this trade, as the French were in the reign of king Henry IV. or the Iriſh at the Revolution; where by the force of public encouragement, it has arrived to an extraordinary pitch, and it is to be hoped will daily advance: the Scots have it not to begin, they want only to improve and extend it to the height it will admit.

The balance of trade between England and Scotland, and England and Ireland, is on the Engliſh ſide; and ſo far as England and its dependencies can be ſerved with *linen* from Scotland and Ireland, inſtead of Holland, France, Germany, and Ruſſia, ſo far will England be a gainer by this change in the courſe of trade. The more *linen* the Scots and Iriſh can ſell in England, the more of the Engliſh commodities will they be able to purchaſe: and it may be reaſonably ſuppoſed that their demands from England will always increaſe in proportion to the increaſe of their people and *linen* manufactures. It is then evidently the intereſt of England to promote and advance the manufacture of *linen* in Scotland and Ireland, and to give them all reaſonable advantages in the trade, in preference to foreigners; where the balance of trade is againſt us, and this ſeems to be the ſenſe of the nation, ſince all foreign *linen*, for home conſumption, pays a duty. Poſt. Dict. Com.

The *linen* trade of this country is regulated by ſeveral ſtatutes.

No perſon ſhall put to ſale any piece of dowlas *linen*, &c. unleſs the juſt length be expreſſed thereon, on pain of forfeiting the ſame. 28 Henr. VIII. cap. 5. Uſing means whereby *linen* cloth ſhall be made deceitfully, incurs a forfeiture of the *linen*, and a month's impriſonment. Stat. 1 Eliz. cap. 12. Any perſons may ſet up trades for dreſſing hemp or flax, and making thread for *linen* cloth, &c. 15 Car. II. cap. 15.

By 10 Ann. cap. 19. and 12 Ann. ſtat. 2. cap. 9. a duty of 3*s*. for every 100*l*. value, over and above other duties, is laid on all ſtriped and printed *linens* imported: and the ſaid printed *linens* are required to be ſtamped by the officers of the cuſtoms: and alſo by the ſame ſtatutes, a home duty of 3*d*. a yard in length, reckoning yard-wide, is laid on all *linen*-ſtuffs, printed, &c. in Great Britain; and for all CALLICOES *ſtuffs*, a yard, excepting thoſe callicoes, *linens*, which ſhall be dyed throughout of one colour only; and on all cottons, wholly made of cotton ſpun in Great Britain, printed, &c. 3*d*. a yard. 14 Geo. III. cap. 72. By 7 Geo. III. cap. 28. certain additional duties on importation are impoſed, viz. for every ell of *linen*-cloth or ſheeting, above one yard wide, except Flanders Holland cloth, 3*d*. and for every ell of *linen* cloth called drilling 3*d*. And by 7 Geo. III. cap. 58. for every ell of foreign *linen*, called packing-canvas, ſpruce-ſibing, or Queensborough-canvas, one farthing; for every ell of Dutch barras, and Heſſian canvas, one halfpenny; and for every yard of foreign lawn, bleached in Holland, commonly called Holland whited lawn, one penny. Houſes for printing, &c. *linen*, are to be entered, on pain of 30*l*. 10 Ann. cap. 19. And if other places are made uſe of beſides the uſual abode of the printer, &c. they are to be entered on pain of 50*l*. and forfeiture of goods. 1 Geo. ſtat. 2. cap. 36. Officers are to enter and take account without obſtruction, on pain of 20*l*. and the goods ſhall be entered once in ſix weeks, on oath, on pain of 50*l*. Concealment of goods to avoid the duty incurs a forfeiture of 20*l*. The duties ſhall be paid within ſix weeks after entry on pain of forfeiting double; and the goods ſhall not be removed before they are ſtamped, on pain of 20*l*. the ſurveyed goods are to be kept ſeparate from the others, and warrants may be iſſued in order to ſearch for goods unſtamped. 10 Ann. cap. 19. Such goods may be ſeized, and the perſon in whoſe cuſtody they are found ſhall forfeit 50*l*. 5 Geo. cap. 21. Counterfeiting the ſtamp is felony without benefit of clergy; and a perſon knowingly ſelling goods with a counterfeit ſtamp ſhall forfeit 20*l*. and ſtand in the pillory. 10 Ann. cap. 19. 13 Geo. III. cap. 56. Theſe goods having paid the duty may be exported, and there ſhall be a drawback of the duties. 10 Ann. cap. 19. 12 Ann. ſtat. 2. cap. 9. *Linen* of all ſorts made of flax or hemp, of the manufacture of this kingdom, may be exported, duty free. 3 Geo. I. cap. 7. CAMBRICS and lawns made in England are to be marked by the exciſe officers, and are regulated under ſeveral penalties. 4 Geo. III. cap. 37. 7 Geo. III. cap. 43. Stealing of *linen*, fuſtian, cotton goods, &c. from whitening-grounds or drying-houſes, to the value of 10*s*. or knowingly buying or receiving ſuch ſtolen goods, is felony without benefit of clergy. 18 Geo. II. cap. 27. Such alſo is breaking into houſes, ſhops, &c. and deſtroying any *linen*-cloth, or implements uſed in the manufacture of it, by 4 Geo. III. cap. 37. Affixing counterfeit ſtamps on foreign *linens* imported, in imitation of the ſtamps put on Scotch or Iriſh *linens*, and expoſing them to ſale, and affixing any counterfeit ſtamp on any *linen* of the manufacture of Great Britain or Ireland, in order to vend the ſame as *linens* duly ſtamped, and expoſing ſuch to ſale, incur forfeiture and a penalty of 5*l*. for each piece by 17 Geo. II. cap. 30. The reſtrictions relating to the importation, wearing, and ſelling of foreign cambrics and French lawns, are enacted by 18 Geo. II. cap. 36. 21 Geo. II. cap. 27. 32 Geo. II. cap. 32. and 7 Geo. III. cap. 43. See CAMBRIC.

A new manufacture has been lately ſet on foot in London, for embelliſhing *linen* with flowers and other ornaments of gold leaf. The *linen* looks whiter than moſt of the printed *linens*; the gold is extremely beautiful, and is ſaid to bear waſhing well. See STUFF.

There are many ſubſtances from which a juice or dye is obtained, that will ſtain *linen* of different colours. The juice of the ANACARDIUM, rubbed on *linen* or cotton, gives a reddiſh-brown ſtain, which ſoon deepens in the air into a black, and which has not been diſcharged by waſhing and boiling, with ſoap or alcaline ley. Hence the anacardium is ſaid to be uſed for marking *linen* and cotton cloths, and to be known all over India by the name of marking-nut. The juice of the CASHEW-*nut*, called by ſome the anacardium of the Weſt Indies, differs from the oriental anacardium in its colouring quality; that lodged between its ſhells being much paler, and giving to *linen*, cotton, or paper, only a brownish ſtain, which is durable, but does not change at all towards blackneſs.

Several ſpecies of the toxicodendron or POISON-*wood*, contain in their leaves a milky juice, which, in drying, becomes of a deep black, and communicates the ſame colour to the *linen* on which it is dropped: the *linen* thus ſtained, boiled with ſoap, came out without the leaſt diminution of its colour, nor does ſtrong ley of wood-aſhes make any change in it. Phil. Tranſ. vol. xlix. for 1755.

Dr. Lewis has found, that the milks of wild poppies, garden poppies, dandelion, hawk-weed, and ſow-thiſtle, gave brown, or brownniſh-red ſtains, which were diſcharged by waſhing with ſoap: the colourleſs juice which iſſues from hop-ſtalks when cut, ſtains *linen* of a pale-reddiſh or brownniſh-red, extremely durable: the juice of ſloes

floes gave likewise a pale brownish ſtain, which, by repeated waſhings with ſoap, and wetting with ſtrong ſolution of alkaline ſalt, was darkened to a deeper brown: on baking the floes, their juice turns red, and the red ſtain which it then imparts to *linen* is, on waſhing with ſoap, changed to a pale-bluiſh, which alſo proves durable. See DYING of *Thread*.

The late Dr. Smellie has recommended the following method of marking *linen*, ſo as not to waſh out again: take vermillion, as much as will lie on a half-crown piece, of the ſalt of ſteel a piece about the ſize of a ſmall nutmeg, grind or levigate them well together with linſeed oil; the compoſition may be diluted or thickened at pleaſure.

LINEN, *faſſil*. See AMIANTHUS and ASBESTOS.

LINEN-*cloth*. See MILL.

LINEN, *white*. See WHITE.

LINEN, *bleaching of*. See BLEACHING.

LING, in *Ichthyology*, the Engliſh name for a kind of fiſh, which is a ſpecies of the ASELLUS, according to the generality of authors, and is generally called *aſellus longus*. According to the new Artedian ſyſtem, it is a ſpecies of the *gadus*, and is diſtinguiſhed by the expreſſive name of the GADUS with two fins on the back, with a bearded mouth, and with the upper jaw longeſt.

Ling, which is the *gadus molva* of Linnæus, is eſteemed, both freſh and cured, for the table. It is a long-bodied fiſh, whence its name by corruption of *long*, being uſually from three to four feet, more approaching to the *merluccius* or hake, than to any other ſpecies; it is covered with very ſmall ſcales, which adhere cloſely to the ſkin; the back and ſides are of a bluiſh or greeniſh brown, and the belly white; its head is flat and large, and its ſnout conſiderably long; the upper jaw is longer than the under, and both are furniſhed with ſeveral rows of ſhort teeth, and the lower with one range of longer; and in the palate there are a large number of ſmall teeth, among which there are four or five large and long ones intermixed; the mouth opens very wide, and in the angle of the lower jaw has a ſingle ſhort beard; it has two fins upon the back, one near the head, conſiſting of fifteen rays, the other not far behind it, and reaching down almoſt to the tail, conſiſting of ſixty-five rays; the gill-fins are ſmall, the belly-fins are placed high, and the tail is rounded at the end, marked with a tranſverſe black bar, and tipt with white. See *Table II. of Fiſhes*, N° 18.

The *ling* abounds about the Scilly iſles, on the coaſts of Scarborough, and thoſe of Scotland and Ireland, and forms a conſiderable article of commerce. In the Yorkſhire ſeas they are in perfection from the beginning of February to the beginning of May, and ſome till the end of that month. They ſpawn in June, at which time the males ſeparate from the females. When the *ling* is in ſeaſon, its liver is very white and abounds with a fine flavoured oil, which afterwards becomes red like that of a bullock, and affords no oil. This oil is ſaid to be boarded up in the cellular membranes of fiſhes, to return into their blood, and to ſupport them in the engendering ſeaſon. Great quantities of this fiſh are ſalted for exportation, and for home-conſumption: for this purpoſe it muſt meaſure twenty-ſix inches or upwards from the ſhoulder to the tail, in order to be entitled to the bounty on exportation. Thoſe under this ſize are called *drizzles*. Pennant.

LINGUA, in *Anatomy*. See TONGUE.

LINGUA *avis*, *bird-tongue*, in the *Materia Medica*, the ſeed of the aſh-tree, or aſhen keys.

LINGUÆ *frænum*. See FRENUM.

LINGUÆ *muſculus*. See MUSCULUS.

LINGUÆ *ſecundus par*, a name given by Caſſerius to a pair of muſcles of the tongue, called by the generality of authors STYLOGLOSSUS.

LINGUADO, in *Ichthyology*, the name of a Weſt Indian fiſh, in ſhape reſembling a ſoal.

LINGUATULA, in *Ichthyology*, the name of a ſpecies of fiſh, ſomewhat reſembling the ſoal, but ſmaller and ſhorter, and much inferior to it in taſte. It is common in the Mediterranean, and brought to market at Rome, Venice, and elſewhere, and is called by other authors CYNOGLOSSUS, and *callionymus*, or *uranoſcopus after*.

LINGUIFORM-*leaf*, among *Botaniſts*. See LEAF.

LINGULA, in *Ichthyology*, the name of an extremely ſmall fiſh of the ſoal-kind. It is known from the reſt of this genus not only by its ſmallneſs, but by a ridge of ſmall ſcales which run along the line over the ſpine, and are much more elevated and diſtinguiſhable, both to the eye and touch, than thoſe of the reſt of the body. It is a well-taſted fiſh, and much firmer in its fleſh than the ſoal, but is very ſcarce, and is of little value, becauſe of its thinneſs. It is caught in the Mediterranean.

LINGULACA, in *Ichthyology*, a name by which ſeveral authors, particularly ſome of the older naturaliſts, have called the *paſtinaca*.

LINIFICUS *lapis*, a name given by ſome authors to a ſtone, which was ſaid to cure the epilepſy when taken internally. It ſeems to have been a name given by ſome fanciful writers to the ALUMEN *phrenſicum*.

LINIMENT, *Linimentum*, from the Latin *linire*, *to anoint gently*, in *Pharmacy*, a form of external medicine, made of unctuous ſubſtances, uſed to rub on any diſtempered part.

The *liniment* is of a mean conſiſtence between an oil and an unguent.

The uſe of *liniments* is to ſoften aſperities of the ſkin, moiſten parts that need humectation, reſolve the humours that afflict the patient, and give him eaſe. There are various kinds of *liniments* uſed, according to the various occaſions.

LINIMENTUM *album*, a form of medicine differing in nothing from the *unguentum album*, but in that it is a little ſofter: they are both preſcribed in the late London Pharmacopœia, and both made of the ſame ingredients. The preſcription for this is as follows: take oil-olive three ounces, ſpermaceti ſix drachms, white-wax two drachms; melt all together over a gentle fire, ſtirring it till it is perfectly cold.

This *liniment* may be applied in caſes of excoriation, where, on account of the largeneſs of the ſurface, the ointment with lead or calamine, might be improper.

LINIMENTUM *arcæi*. See ELEMI.

LINIMENTUM *ſaponaceum*, the ſoap-*liniment*, a form of medicine preſcribed in the late London Pharmacopœia, and meant to ſupply the place of the ointment well known by the name of *opodeldoc*. It is made thus: take ſpirit of roſemary a pint, hard Spaniſh ſoap three ounces, camphor one ounce; digeſt the ſoap with the roſemary ſpirit, till it is diſſolved, and then add the camphor; when this is melted, the whole is finiſhed.

A *liniment* of this kind may be prepared by rubbing an ounce of camphor, with two ounces of Florence oil, in a mortar, till the camphor be diſſolved. This anti-ſpaſmodic *liniment* may be uſed in obſtinate rheumatiſms, and in ſome other caſes, accompanied with extreme pain and tenſion of the parts.

LINIMENTUM *volatile*, a form of medicine preſcribed in the late London Diſpenſatory, and ordered to be made of oil of almonds, an ounce; ſpirit of ſal armoniac, made without lime, two drachms; theſe are to be ſhook together in a wide-mouthed vial, till they are perfectly mixed. Or this *liniment* may be prepared by ſhaking together an ounce of Florence oil, and half an ounce of ſpirit of hartſhorn. If the patient's ſkin is able to bear it, the *liniment*, made with equal parts of the ſpirit and oil, will be more efficacious. Sir John Pringle obſerves, that in the inflammatory quinſey, a piece of flannel moiſtened with this *liniment* and applied to the throat, to be renewed every four or five hours, is one of the moſt efficacious remedies; and that it ſeldom fails, after bleeding, either to leſſen or carry off the complaint.

A *liniment* for burns may be made by ſhaking well together in a wide-mouthed bottle equal parts of Florence oil, or of freſh drawn linſeed oil, and lime-water. This is found to be an exceeding proper application for recent ſcalds or burns. It may either be ſpread upon a cloth, or the parts affected may be anointed with it twice or thrice a day.

A *liniment* for the piles may be made by mixing two ounces of emollient ointment, and half an ounce of liquid laudanum, with the yolk of an egg, and working them well together.

LINKIO, in *Botany*, a kind of water-plant among the Chineſe, the fruit of which is of a triangular pyramidical form, prominent every way, with a green thick rind, that grows reddiſh towards the apex, and, when the fruit is dried, grows black. The internal ſubſtance is exceeding white, its taſte like that of a cheſnut, three or four of which it equals in bulk. The plant is found in ſtanding waters, and has very ſlender leaves, that ſpread themſelves over a large extent on the ſurface of the water, and the fruit lies concealed under water in great numbers.

LINNÆA, in *Botany*, the name of a genus of plants of the *didynamia angioſpermia* claſs, given by Gronovius in honour of his friend Linnæus, the characters of which are theſe: the cup is a double perianthium; the perianthium of the fruit conſiſts of two leaves; the perianthium of the flower ſtands upon the germen, and is narrow, erect, and acute, and compoſed of one leaf divided into five ſegments; the flower is monopetalous, of a campanulated form; it is twice as large as the cup, and is ſlightly divided into five ſegments at the edge; the ſtamina are four ſubulated filaments, inſerted in the baſe of the flower; two of theſe are very ſhort, but the two longer are not ſo long as the flower; the antheræ are of a very compreſſed figure, and can turn round upon the ſtamina; the germen of the piſtil is roundiſh,

roundish, and is placed within the cup; the style is straight and slender, and is of the length of the flower; it always bends toward one side, and is terminated by a globose stigma: the fruit is a dry oval berry of three cells, and is covered with the hairy and glutinous cup of the flower; the seeds are single and roundish. There is only one species.

LINNEAN *system of botany*. See BOTANY, FLOWERS, and SEXUAL *System*.

LINNET, *linaria*, in *Ornithology*, a genus of birds, of which there are several species. The general characters of the genus are these: the birds of it are somewhat smaller than the chaffinch: their general colour is a greyish-brown; their tail is a little forked, the outer feathers of it having white extremities: and they all sing very sweetly. We have in England four species of this bird.

1. The common brown *linnet*, well known to every one. These birds are much esteemed for their song; they feed on seeds of different kinds, which they peel before they eat: the seed of the *linum* or flax is their favourite food, whence the name of the *linnet* tribe.

2. The *linaria rubra major*, or greater red-headed *linnet*: the FRINGILLA *cannabina* of Linnæus. This has a fine red head, a grey neck, a dusky reddish-brown back, and its breast and belly are somewhat reddish. The female of this species, however, has no redness in its head or breast, but has somewhat of a greenish cast on the brown of its back, and is yellowish on the breast, with some brownish spots. It is a common braid in the birdshops in London, when a male bird is distinguished from a female by a red breast, as in the case of this bird, to stain or paint the feathers, so that the deceit is not easily discovered, without close inspection. This species of *linnet* is frequent on our sea-coasts, and is often taken in the time near London. It is a familiar bird, and becomes chearful in five minutes after it is caught.

3. The *linaria rubra minor*, or lesser red-headed *linnet*: the FRINGILLA *linaria* of Linnæus. This is the least of all the *linnets*, and on the back is of the same colour with the common *linnet*; the back part of its head is red, and also its breast, but the lower part of its belly is whitish. In this species, the female as well as the male, has a red head; that of the male being ornamented with a rich shining spot of a purplish red, and that of the female of a saffron colour; and both have their beaks much sharper, and their feet and legs blacker than in the larger kind. This is a gregarious bird, whereas the larger species commonly flies single. This seems to be the species known about London by the name of stone red-poll.

4. The last species is the *linaria montana*, or mountain-*linnet*. This is the largest of all the *linnets*, according to Willoughby's description, though Mr. Pennant says that it is in fize rather inferior to the common *linnet*. Its beak is very small; its head and back are of the same colour with those of the common *linnet*, and the feathers of its breast and belly are black, edged with white; the rump of the male is of a fine and beautiful red, and thus distinguishes it from the female. This species is common in Derbyshire, but seems not so frequent in other places. However it is taken in the fame manner near London with the *linnets*, and called a *twite*. It breeds, according to Mr. Pennant, only in the northern parts of our island. Ray and Pennant.

It is remarkable of the *linnet*, that when it builds in hedges, and when in furze-bushes on heaths, in both which places the nests are very common, they are made of different materials. When they build in hedges, they use the finest filaments of the roots of trees, and the down of feathers and thistles; but when they build in heaths, they use moss, principally, for the outer part, finishing it within with such things as the place will afford, chiefly with wool and hair. These birds will have young ones three or four times a year, especially if they are taken away before they are able to leave the nests. They lay five whitish eggs, spotted like those of the gold-finch.

When they are intended to be taught to whistle tunes, or to imitate the notes of any other bird, they are to be taken from the old one when they are not more than four days old; for at this time they have no idea of the note of the old ones, and will readily be taught to modulate their voice like any thing that is most familiar to their ears, and within the compass of their throats. The honourable Mr. Barrington observes, that in order to be certain that a nestling will not have the call of its species, it should be taken from the nest when only a day or two old; though a bird of this age requires great trouble in breeding, and the chance is greatly against its being reared. There requires more care in the feeding them when they are taken thus young, than when they are left in the nest till nearly fledged, but they will be reared very well upon a food half bread and half rape-feed, boiled and bruised: this must be given them several times a day. It must be made fresh every day, and given them sufficiently moist, but not in the extreme. If it be in the least sour, it gripes and kills them; and if too stiff, it is as mischievous, by binding them up.

They must be hung up as soon as taken from the nest, under the bird whose note they are intended to learn; or if they are to be taught to whistle tunes, it must be done by giving them lessons at the time of feeding; for they will profit more while young in a few days, than in a long time afterwards, and will take in the whole method of their notes before they are able to crack hard seeds. Some have attempted to teach them to speak, in the manner of the parrot, or other birds, and they will arrive at some sort of perfection in it with great pains.

Mr. Barrington mentions a *linnet*, which, being taken from its nest when only two or three days old, almost articulated the words *pretty boy*, as well as some other short sentences. See SONG *of birds*.

LINOZOSTIS, in *Botany*, a name given by the ancient Greek writers to two plants very different from one another; the one is the *mercurialis*, or English mercury, a plant common in uncultivated places, and eaten by many boiled in the manner of asparagus; the other the *epithimum*, or dodder, growing upon the plants of flax. Theophraftus, Dioscorides, and the ancient Greeks, use the word in the firft fenfe, and the modern Greeks in the latter.

The Latin authors call this *linozoftis*, or *epithimum*, sometimes *cuscuta lini*, and *podagra lini*, looking on it as a diseafe which chokes the plant it grows on, and caufes gouty tumors on the ftalks. See DODDER.

LINSEED, or LINE-SEED, a fort of grain, being the feeds of the common FLAX, which enters the compofition of feveral medicines, and yields, by expreffion, an oil, that has moft of the qualities of nut-oil, and is according generally ufed, in lieu thereof, in painting, and for burning.

Thofe who manufacture it in large quantities have mills turned by horfes or water, for the more expeditious difpatch of their work.

That drawn without the affiftance of fire, is of much eftcem in medicine, and fuppofed good in the cure of catarrhs, coughs, afthmas, and other diseafes of the breaft, &c.

The quantity of *linfeed* annually imported into England, Scotland and Ireland, is not lefs than 240,000 bufhels.

Linfeed, from which the oil has been expreffed, boiled in milk, and applied warm in a cloth to burnes, is much recommended in the Satyr. Sibelius. fpecim. 4. obf. 4.

Thefe feeds, in this ftate, are frequently employed in emollient and maturating cataplafms. The feeds, boiled in water, yield a large proportion of a ftrong flaxen-like mucilage; but to rectified fpirit they give out little or nothing. Thefe feeds have been fometimes ufed, in a feafon of fcarcity, inftead of grain; but they appear to be an unwholefome as well as unpalatable food. Tragus relates, that thofe who fed upon them in Zealand, had the hypochondres in a fhort time diftended, and the face and other parts fwelled; and that not a few died of thefe complaints.

LINSEED, *infufion of*. See INFUSION.

LINSPINS, or LINCHPINS, are fmall pins of iron, which keep the wheel of a cannon, or waggon, on the axle-tree; for when the end of the axle-tree is put through the nave, the *linfpin* is put in to keep the wheel from falling off.

LINSTOCK, a fhort ftaff of wood, about three feet long, having at one end a piece of iron divided into two branches, each of which has a notch to hold a piece of match, and a fcrew to faften it there; the other end being alfo fhod with iron, and pointed, to ftick into the ground, or in the deck when it is ufed at fea. It is ufed by the gunners in firing cannon. It is frequently ufed in fmall veffels, in an engagement, where there is commonly one fixed between every two guns, by which the match is always kept dry and ready for firing.

LINT, in *Surgery*, is the fcraping of fine linnen, ufed by furgeons in dreffing wounds. It is made into various forms, which acquire different names, according to the difference of their figures.

Lint made up in an oval, or orbicular form, is called a PLEDGET; if in a cylindrical form, or in the fhape of a date or olive-ftone, it is called a TOSTIL.

Thefe different forms of *lint* are required for many purpofes; as, 1. To ftop blood in frefh wounds, by filling them up with dry *lint* before the application of a bandage; though if fcraped *lint* be not at hand, a piece of fine linen may be torn into fmall rags, and applied in the fame manner. In very large hæmorrhages the *lint*, or rags, fhould be firft dipt in fome ftyptic liquor, alcohol, or oil of turpentine, or ftrinkled with a ftyptic powder.

2. To

2. To agglutinate and heal wounds; to which end *lint* is very serviceable, if spread with some digestive ointment, or balsam, or dipt in some vulnerary liquor. 3. In drying up wounds and ulcers, and forwarding the formation of a cicatrix. 4. In keeping the lips of wounds at a proper distance, that they may not hastily unite, before the bottom is well digested and healed. 5. They are highly necessary to preserve wounds from the injuries of the air. Small portions of *lint* tied round with a thread are chiefly used in dressing wounds and ulcers of the deeper kind. They are always applied to the bottom of such wounds, the remaining cavity being filled up with other portions of *lint*. By this means, the immediate removal of the dressings is not only provided for, but the possibility of leaving any part of them in the bottom of the wound is prevented.

In very large wounds, and especially in amputations of the limbs, which operations are frequently required in the army and navy, at times when *lint* is very scarce, it will be very sufficient to dress the bare bone and face of the wound with scraped *lint*, filling up the cavity with tow, and covering all with a large compress.

Surgeons of former ages formed compresses of sponge, feathers, wool, or cotton, linen being scarce; but *lint* is far preferable to all these, and is at present universally used. Heist. Surg. Introd. sect. 54.

LINTEL, in *Architecture*, the piece of timber which lies horizontally over door-posts and window-jambs; as well to bear the thickness of the wall over it, as to bind the sides of the walls together.

LINUPAR, in *Botany*, a name used by some of the writers of the middle ages, to express the water-lily. The Arabians gave this genus of plants the name of NILUFAR, and this word *linufar* is only formed of that, by transposing some of the letters.

LINUM, in *Botany*. See FLAX.

LINUM *carpasium*, *carpasian flax*, or *linen*, a term often occurring in the old writers, and used by different authors in very different senses.

The first use we find made of the word, is for the expressing a kind of *flax* which was finer and smaller, as well as brighter and more glossy than any other. Pliny uses the word in this sense, and tells us, that such *flax* was principally brought from Spain; and that both it, and the *linen* made of it, were, at his time, called by the name *carpasian*: from this it became a custom to call all very fine flax, or fine *linen*, *carpasian linen*, and the word signified no more than delicate, or fine.

The modern Greeks use the word in this sense, and Suidas expresses the finest *linen* veils by the term *carpasian*. The author of the Periplus Maris Erythræi, who was contemporary with Pliny, calls the *flax*, of which the Indian *linens* were made, *carpasos*; but none of the older Greeks have the word. This author is not, however, to be appealed to for ascertaining the purity of the language of the ancients; for it is plain that he has taken in many words which are not good Greek, nor ever were used by any author of credit, but are the mere technical terms of the tradesmen and merchants of that time.

Pausanias uses the word *carpasinon linum* in a very different sense from all these; for with him it is made to express the *flax* made of the stone ASBESTOS, and the *linen* made of this, which was thrown into the fire to be cleaned. Solinus uses the word also in the same sense: he says, that in Carystos there was found that kind of *flax* which remained unhurt in the fire; and Hieronymus Mercurialis thinks that the *carbasus* of the ancient Romans was a word properly used only to signify the *carpasian flax* of Pausanias, which was not to be destroyed by the fire, and was the true *linum incombustibile*, or threads of the asbestos stone, or *linen* made of that material. This, however, is not the sense of the word in later times, for we find it evidently used for all *linen* manufactures of whatever kind.

LINUM, *carystium*, in *Natural History*, a name given by Pausanias to the ASBESTOS. It was found plentifully, in this author's time, near Carystos, a town in the Negropont, and thence obtained its name.

LINUM *catharticum*, *purging-flax*, in *Medicine*, makes a common purge among the country people. It is almost as rough as that of *gratiola*.

It is a species of wild *flax*, distinguished by the name of meadow-*flax*, with small flowers which appear in July, and commonly called mountain-*flax*, growing without culture on chalky hills and dry pasture grounds in many parts of England, and is taken in infusion in ale.

This herb is said to be an effectual and safe cathartic: an infusion of a handful of the fresh leaves in whey or white wine, or a dram of the leaves in substance with a little cream of tartar and aniseeds, are directed for a dose. Linnæus recommends an infusion of two drams of the dry leaves as a mild laxative.

It is greatly recommended by some in dropsies; and to prevent its griping they mix anise or some other of the carminative seeds with it. It is given in most chronic cases, where people's constitutions are strong enough to bear it, and often with great success.

LINUM *vivum*, or *incombustible*, cloth made of a fossile, stony substance, of a whitish colour, and woolly texture, separable into threads, or filaments, which will endure the fire without consuming. See ASBESTOS.

As to the art of managing this mineral, and of spinning and weaving it, &c. the accounts we have are various. Marco Polo, the Venetian, gives us the manufacture of the *linum*, found in the province of Chinchintbelas in Tartary, from one Curfica, a Turk, superintendant of the mines of that country, as follows. The lanuginous mineral, being first dried in the sun, is then pounded in a brass mortar, and the earthy part separated from the woolly, which is afterwards well washed from filth; being thus purged, it is spun into thread like other wool, and after woven into cloth, which if foul or spotted, they cleanse, he says, by throwing it into the fire for an hour's time, whence it comes out unhurt, as white as snow: which very method, according to the account given us by Strabo, seems to have been used, in ordering the Cretan amianthus; with this addition, that after it was pounded, and the earthy part separated from the woolly, he says it was combed; and so does Agricola. Signior Ciampani, after describing four sorts of the *linum*, whereof he had specimens in his museum; the first sent him from Corsu, the second from Sestri di Ponente, the third coarser and darker than the rest, and the fourth from the Pyrenean; and after observing, that though he kept it three weeks in a glass-house fire, yet he found it unaltered, though it could not preserve a stick, wrapped in it, from the fire; he proceeds to shew the manner of spinning, and making it into cloth, which he effected thus:—He first laid the stone in water, if warm the better, for some time to soak; then opened and divided it with his hands, that the earthy parts might fall out of it, which are whitish like chalk, and serve to bind the thready parts together. This makes the water thick and milky. That operation he repeated six or seven times, with fresh water, opening and squeezing it again and again, till all the heterogenous parts were washed out, and then the flax-like parts were collected, and laid in a sieve to dry. As to the spinning, he first shews a method discovered to him, which is thus:—Lay the *linum*, cleansed as before, between two cards, such as they card wool withal, where let it be gently carded, and then clapped in between the cards, so that some of it may hang out of the sides; then lay the cards fast on a table, or bench; take a small reel, made with a little hook at the end, and a part to turn it by, so that it may be easily turned round; this reel must be wound over with white thread: then, having a small vessel of oil ready, with which the fore finger and thumb are constantly to be kept wet, both to preserve the skin from the corrosive quality of the stone, and to render the filaments thereof more soft and pliant; by continuing to twist about the thread on the reel in the asbestos hanging out of the cards, some of the latter will be worked up together in it; and, by little and little, the thread may, with care, be woven into a coarse sort of cloth; and, by putting it into the fire, the thread and oil will be burnt away, and the incombustible cloth remain.

But finding this way, of uniting the stone with the thread, very tedious; instead of the thread, he put some flax on a distaff, and, by taking three or four filaments of the asbestos, and mixing them with the flax, he found, they might be easily twisted together, and the thread thus made much more durable, and strong; so that there is no need of carding, which rather breaks the filaments, than does any good: only open and separate the filaments, after washing, on a table, and take them up with the flax, which is sufficient.

As to the making of paper, he says, in the washing of the stone there will remain several short pieces in the bottom of the water, of which paper may be made in the common method. He concludes with the best way of preserving the cloth, or any thing made of the linen, which, by reason of its excessive dryness, is very apt to break, and twist; and it consists in keeping it always well oiled, which is the only preservative. When the cloth is put in the fire, the oil burns off, and the cloth comes out white and purified. See ASBESTOS.

LION, *Leo*, in the Linnæan system of *Zoology*, is a species of quadrupeds, belonging to the FELIS or *cat* kind, with a long tail and pale-red or tawny body.

The head of the *lion* appears very large, in proportion to its body, and is the most fleshy of the heads of all the known animals; its jaw-bones also are remarkably large; the breast also appears very large, but this is only owing

to the great quantity of long hair that covers it, for the ſternum is ſmaller than that of moſt animals of the ſame ſize; the tail, which is very long, appears alſo of the ſame thickneſs all the way, but this is wholly owing to the growth of the hair; the tail itſelf is largeſt at the baſe, and thence goes taper to the point; but the hair being very ſhort near its baſe, and continuing to grow longer all the way, as that decreaſes in thickneſs, is ſo exactly proportioned in its growth, that it always gives the whole tail this regular appearance. The length of the largeſt *lion* from noſe to tail is above eight feet; the tail is four feet. See *Tab.* III. *of Quadrupeds*, N° 27.

The long hair that grows about the neck and breaſt, and makes what is called the mane of a *lion*, only differs from the hair of the reſt of the body in length, having no greater thickneſs or rigidity, like that of the manes of other animals. The claws of the *lion* have no caſes, as Pliny pretends that they have, for the animal to withdraw them into in walking; but Plutarch, Solinus, and ſome others, are much more in the right in ſaying that the *lion* draws them up backwards when he walks, and places them cloſely among the articulations of the toes.

The tongue of the *lion* is very rough and rigid, being covered with a great number of prominences of a hard matter, reſembling that of a cat's claws, and theſe are much in the ſhape of thoſe claws, and nearly of the ſame ſize, the baſe of each being a round fleſhy prominence on the ſurface of the tongue.

The eyes of the *lion* are clear and bright, even after the creature is dead. The common obſervation that this creature ſleeps with its eyes open, is founded on this, that it has a very thick membrane lodged in the greater canthus of the eye, which it can extend over the whole eye upon occaſion, as birds do their *membrana nictitans*, and thus will have no occaſion to ſhut its eye-lids, in order to exclude the light. It is very remarkable, that the common cat has all the ſingular ſtructure of the ſeveral parts as the *lion* has, its claws, feet, tongue, and eyes, being of the ſame kind, and its internal parts bearing as ſtrong a reſemblance.

The heart of a *lion* is much larger than that of any other creature of the ſame ſize, being ſix inches long, and four in diameter, in the largeſt part, and terminating in a very ſharp point; and the brain is as remarkably ſmall.

The *female* has no mane, or long hairs upon the neck and breaſt, which ſo remarkably characteriſes the *lion*. The noſe alſo is longer in the *female*, and the head more flatted in the upper part; the claws alſo are much ſmaller than thoſe of the male *lion*. This creature, when full grown, is about three feet high, from the fore-feet to the ridge of the back, and about five feet long from the end of the noſe to the inſertion of the tail, which is about two feet and a half long; the claws are of a fibrous texture, the fibres being very hard in themſelves, but eaſily ſeparable from one another. In other particulars, the *female* very little differs from the *lion*. See *Tab.* III. *of Quadrupeds*, N° 28.

The *lion* is an inhabitant of all parts of Africa, and the hot parts of Aſia, ſuch as India and Perſia, and ſome few are found in the deſerts between Bagdat and Baſſorah, on the banks of the Euphrates; but they moſt abound in the torrid zone, where their ſize is the largeſt, and their rage moſt tremendous, being inflamed by the influence of a burning ſun on a very dry ſoil. It is obſerved, that, though they reign abſolute maſters over every beaſt, their rage diminiſhes and their timidity increaſes as they approach the habitation of the human race. They have been alſo known to ſpare the weaker animals, and many inſtances are related by A. Gellius, Ælian, and Pliny, &c. of their gratitude. *Lions* are capable of being tamed; and the monarch of Perſia is ſaid on days of audience, to have two large *lions* chained on each ſide of the paſſage to the room of ſtate, led there by keepers in chains of gold. The *lion* preys on all kinds of animals; having rouſed them into view by his roar, he ſtarts on his prey, ſtriking it with his talons and tearing it to pieces. He alſo invades the folds, leaping over the fences with his prey, and his ſtrength is ſo great, that he can carry off a middling ox with the utmoſt eaſe. He ſometimes ſeizes his prey by ſurpriſe, and mankind falls a victim to his hunger, more through neceſſity, as it is ſaid, than choice. The Arabs have a notion of his ſparing the tender ſex, but Dr. Shaw informs us in his Travels, p. 244, that the *lion* obſerves no diſtinctions in theſe days. The fleſh is often eaten in Barbary, and is ſaid to reſemble veal in taſte. Pennant's Brit. Zool. p. 165, &c.

The French, when they had once a ſick *lion*, attempted to recover him from his ſickneſs by ſuch foods as nature never intended him, that is, by the tender and pure fleſh of young animals, without any of the external coat. They gave him young lambs ſkin'd alive for this purpoſe; but nature not having given this animal the ſubtlety to flay his food, and the hair, wool, feathers, &c. being as neceſſary to theſe beaſts of prey with the fleſh, as that fleſh itſelf, the new food bred too much blood, and proved a worſe diſeaſe than that he had before, ſo that he ſoon died.

LION, *ſea*. See SEA-*Lion*.

LION-*pucceron*, in *Natural Hiſtory*, the name given by Mr. Reaumur to a genus of worms which deſtroy the *pucerons* in the ſame manner that the *formica leo* does the ants.

Theſe little inſects are a prey alſo to a ſort of worm hatched from the egg of a two-winged fly. This has no legs, and is of ſeveral colours. See VER-*pucceron*.

Though theſe *lion-pucerons* be all hexapodes, yet they are of different origin; ſome being produced from the eggs of a four-winged fly, others from thoſe of a beetle. As the *formica leo* has two horns, the extremities of which ſerve him by way of mouths, our *lion-pucceron* has the ſame kind alſo; but as the former of theſe inſects can only move backwards, and is forced to make ſnares for his prey, not being able to hunt it, this creature runs very nimbly in the common way, and ſeizes its prey, without having recourſe to ſuch ſtratagems.

The body of the *lion-pucceron* is longer than that of the *formica leo*, and is flat; the breaſt is the thickeſt and broadeſt part of it, and from this it gradually tapers off to a point at the tail; it has two legs fixed to the breaſt, the other four to the anterior rings of the body, and when it moves, the poſterior end of the body ſerves it in the place of a ſeventh leg, for it always bends it downward, and draws it along the ſurface it walks upon. The back of this creature is not ſmooth or gloſſy, but is every where rough, and full of wrinkles, and ſeems as if every ring of it was compoſed of ſeveral other ſmaller rings.

This is the general deſcription of the creature, treating of it in the general way, theſe characters ſuiting all the kinds of it. There are others, however, by which the whole claſs may be divided into three principal kinds.

Theſe are much more voracious devourers of the *pucerons*, than the worms which feed on them. A ſmall *pucceron*, ſeized by one of them, is eaten in an inſtant, and the very largeſt is not the work of half a minute for them. Theſe creatures are very ſmall when firſt produced from the egg, and yet they immediately begin to feed. They are ſo ravenous of food alſo, that whenever they can they catch and eat one another. But as the *pucerons*, among which they live, are eaſier to be caught, they uſually eſcape one another's fury pretty well; unleſs where there is a ſcarcity of the *pucerons*, or when they offend one another.

It is eaſy to conceive that a creature, which feeds ſo very faſt, muſt ſoon arrive at its full growth; and this is the caſe with theſe animals, for within five or ſix days of their being hatched from the egg, they are ready for their final tranſformation, or the putting on the form of the animals to whoſe eggs they owed their origin. In order to this, the creature leaves the place where he has hitherto fed, and ſeeks the folds of a leaf, or ſome other ſuch convenient receptacle, where it ſpins a web of very fine ſilk, every way ſurrounding its body with it, and under this cover paſſes the ſtate of a nymph or chryſalis. The ſilk of this web is not only very ſtrong, but the threads are very cloſely laid together, ſo that it is much firmer than the webs of any of the caterpillar kind. It is of a roundiſh figure, and is ſomewhat ſmaller than a pea.

This round figure is owing to the form into which they roll up their body, which ſerves as a mould for it; and the orifice, out of which the ſilky matter is produced, is at the extremity of the poſterior part of the body. The creature continues in this ſtate about three weeks, if it be in the beginning of ſummer that it goes into it; but if toward autumn, it remains in it all the following winter; and is afterwards, in ſpring, ſeen to come out in the form of a very beautiful fly, of a remarkable large ſize, in proportion to the creature it is produced from, and the web out of which it comes. It is a very long bodied one, and much reſembles the libella or dragon-fly, only that its wings are larger in proportion to its body: theſe wings are of a moſt delicately fine ſtructure, the ſmall gawfe being coarſe and thick in compariſon to them. Theſe, when the creature is at reſt, are placed in an angle over the body, and form a ſort of canopy or tent for it, but they are ſo perfectly tranſparent that the body is eaſily ſeen through them. The body and breaſt are all green, and that of a very beautiful tinge; but the moſt remarkable beauty of this creature is in its eyes; theſe are large and prominent, and are of a fine gold colour, and of greater luſtre than the moſt highly poliſhed metal.

The eggs of this fly are a very ſingular object, and cannot have eſcaped the eye of any perſon who is converſant among the inſects which live on trees; though of the many who have ſeen them, perhaps few or none ever found what they really were. It is common to ſee on the

the leaves and pedicles of the leaves of the plum-tree, and several other trees, as also on their young branches, a number of long and slender filaments, running out to about an inch in length, and being of the thickness of a hair; ten or twelve of these are usually seen placed near one another, and a vast number of these clusters are often found on the same tree. The end of each of these filaments is terminated by a sort of swelling or tubercle of the shape of an egg. People who have observed these, have generally supposed them to be of vegetable origin, and that they were a sort of parasitical plants, growing out of others, as the mistetoe, mosses, &c. from the oak and other trees. They very much resemble in figure those species of mouldiness, which Malpighi and others have figured under the shape of little mushrooms, only they are much larger than those little plants, and bear the heat of the sun and other accidents uninjured, which would destroy the tender plants of that kind. There is a time, when these egg-like balls, which terminate every one of these filaments, are found open at their ends, and in this state they very much resemble flowers, and they are in this state figured by some authors under the name of flowers of a singular kind, found on the leaves of the willow. All this, however, is wholly erroneous, and the pursuing the history of our *lion-pucerons*, shews their true origin to be from the fly of that creature. What these authors took for flowers of the willow were only the egg of this fly, out of which the young animals had been hatched, and had made their escape. The leaves and branches on which these eggs are found, are usually seen covered over with the *pucerons*; and the creature providing a place where her young shall find nourishment as soon as hatched, places her eggs in the midst of these harmless and defenceless animals, fixing each on a slender pedicle, yet sufficiently strong to bear its weight. If these eggs be nicely examined, a worm may be discovered in them while yet whole; but the most certain way of judging of them, is, to put several of them into a box, in which case every one of them is found at a proper time to hatch, and to give an insect; which, when viewed by the microscope, appears plainly to be a *lion-pucerons* in all its parts, and requiring only increase in size, without any change of shape, to be one of those we have already described, as feeding so voraciously on the *pucerons*. Reaumur's Hist. Ins. vol. vi. p. 142.

LION, *ant*, in *Zoology*. See FORMICA *Leo*.

Conilia LION'S *foot, cotunnoides*, in *Botany*, a genus of the *syngenesia polygamia aequalis* class. Its characters are these: the flower is composed of many hermaphrodite florets, included in one common scaly empalement, which is permanent and elegant; the florets are of one leaf, tongue-shaped, indented in five parts, and they have each five short hairy stamina; the germen is situated below the flower, and becomes a single oval seed, compressed and crowned with bristles, inclosed in the empalement. There are two species.

LION'S *leaf, leontice*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the empalement of the flower is made up of six very narrow leaves; the flower has six oval acute petals, and six nectaria, which are fixed by small foot-stalks to the base of the petals; it has six stamina; in the centre is placed an oval germen, which becomes a globular, swollen, succulent berry, with one cell inclosing two or three globular seeds. Miller reckons two species, and Linnæus four.

LION'S *tail, leonurus*, in *Botany*, a genus of the *didynamia gymnospermia* class. Its characters are these: the flowers have one petal of the lip kind, the upper lip cylindrical, hairy, and entire; the lower lip reflexed and cut into three parts; it has four stamina, two of which are shorter than the other; in the bottom of the tube, are situated four germina, which become four oblong angular seeds, sitting in the empalement. Linnæus has joined the species of this genus to the PHLOMIS, and has applied this title to the *cardiaca*. See MOTHER-*wort*.

LIONCELES, in *Heraldry*, a term for lions when there are more than two of them borne in any coat of arms, and no ordinary between them.

LIONINE, or LIONAGE, in the history of the *Coins* current in Ireland, a name given to certain coins, imported privately from France and other places. There were beside these many others of the same sort, impressed with eagles, roses, and the like, and called by names signifying those impressions. They were a very base and poor sort of money; the penny *lionine* or *lionine*, not coming up to the value of the halfpenny of the coin of the kingdom. They were discountenanced in the year 1300, and good money being struck there, it was made death, and confiscation of goods, to import any of them: and the run of them was thus stopped.

LIP, in *Anatomy*. See LIPS.

LIP *of a horse*, in the *Manage*, is the skin that covers the sides of the mouth, and surrounds his jaws. A horse is said to arm or guard himself with his *lips*, when his *lips* are so thick, that they cover their bars, and keep off the pressure of the curb.

LIPA, of νειπω, *fat*, a word used frequently by Hippocrates to express any thing fat or oily. He calls certain stools, which have a fatty appearance, by this name. These are esteemed a sign of great colliquation. He also applies it to a sort of fatty substance, often seen swimming on the surface of the urine like a spider's web: this the same great author gives as a sign of a consumption.

LIPARÆUS *lapis*, in the *Natural History of the Ancients*, the name of a stone usually found in Liparis, one of the Æolian Islands, and brought thence in the time of the Greeks among the pumices, of which that place always afforded them a large quantity.

It was a small stone, about the bigness of a filbert, of an irregular and uncertain shape, and porous and friable constitution, like that of the pumices, but more easily falling to pieces on rubbing between the fingers than even the softest of them; the colour was a dusky grey, and the whole external surface plainly shewed that it had suffered changes by the means of fire. The stone at present, however, is so little regarded, that the writers on such subjects have even forgot to name it. They are sometimes brought to us, to this day, among the pumices from the burning mountains, but are not regarded.

LIPARIS, in *Ichthyology*, the name of a fish of the general order of the anguilliformes, or eel-shaped, and most approaching to the blanda, of any species. Its head is shaped somewhat like that of a rabbit. It is brought to the table among other small fish, but is of an insipid taste, and generally either offends the stomach, or urges to stool. It is caught in the Mediterranean and other seas. The name is originally Greek, and is formed of the adjective λιπαρος, *fat*.

The *liparis* is a species of the CYCLOPTERUS in the Linnæan system.

LIPARIS is also used by some for the fish, called by authors the GUNNELLUS, and by the people of Cornwall the *butter-fish*.

LIPARIS, in *Botany*, a name given by some authors to the pinguicula, butterwort, or Yorkshire fanicle.

LIPARIS *austriaca*, in *Ichthyology*, the name of a small fish, common on the coasts of Yorkshire and some other parts of England, and called in English the *snail*, and LIMAX *marinus* by some authors. It is about five fingers long; on its back and sides it is of a bright brown, and on the belly of a fine white: these are its colours, when fresh taken, for when it has been kept ten or twelve hours, the whole surface of the body, except the fins, becomes of a paler and bright brown. The head is thick, and not flat, but rounded; it has no teeth, but its jaws are both rough like files.

The whole fish, head as well as body, is very soft and unctuous, and easily melts into a sort of oily liquor. It is caught principally at the mouths of great rivers where they open into the sea.

LIPOTHYMIA, or LIPOPSYCHIA, in *Medicine*, a sudden diminution, or failure, of animal and vital actions; otherwise called a *swooning* or *deliquium*.

The word *lipothymia* comes from the Greek λειπω, *deficio*, and θυμος, *animus*; and *lipopsychia* from ψυχη, and ψυχω, *the soul*.

This disease is usually confounded with the SYNCOPE, but is really different from it in many particulars.

The *lipothymia* is a very considerable abolition of the vital and animal faculties, at least to appearance; and the syncope is a plenary or total abolition of them, as far as appears to us at the time. It is easy to see, however, that these are only two different stages of the same distemperature. The *lipothymia* is sometimes an idiopathic, sometimes a symptomatic disease, and most frequently attends the scurvy, malignant fevers, and other disorders: the syncope is idiopathic, and attacks persons in health as well as those that are diseased. The *lipothymia* is always easily distinguished from a convulsed state of the body, by this, that the limbs are all flaccid in it. The syncope differs from death only in degree: and the body being flaccid in this, and growing rigid under the last convulsions in death, is the only distinction of them in extreme cases.

Causes of it. The general causes of swooning are sudden transitions from heat to cold, breathing hot foul *phlogisticated* AIR, great fatigue, excessive weakness, loss of blood, long fasting, fear, grief, and other violent passions of the mind.

Signs of it. The *lipothymia* is usually preceded by a remarkable anxiety about the heart, and this is succeeded by an immediate loss of life and motion for a time: the senses, and the animal motions, and even the pulse,

seeming all to be loſt for a time; and the heart flutters weakly, or trembles, and reſpiration is ſcarce ſenſible. In the ſyncope, the reſpiration as well as the pulſe ſeem wholly impeded, and the patient appears wholly dead; the face looks as pale as in a corpſe, and the limbs are wholly flaccid, and without motion. The extremities grow cold, and the eyes are either ſhut, or turgid, and inflamed; the mouth is ſometimes ſhut, but not clenched firmly together as in convulſions, and ſometimes it continues frightfully open; and as ſoon as the paſſion comes to himſelf he uſually ſighs ſeveral times, and reſpiration ſeems very much laboured.

Perſons ſubject to it. The idiopathic *lipothymy* is a very uncommon complaint, and the perſons ſubject to it are thoſe of weak nerves, delicate conſtitution, and of a tender and ſenſible diſpoſition, who are eaſily affected by the ſeveral paſſions, and particularly by fear; or ſuch as have been before frequently ſubject to it in diſeaſes, or are of a melancholic habit. People who uſe inceſſant ſtudy for a long time on many occaſions, alſo ſometimes fall into it, women with child are alſo ſubject to it from the preſſure of the breaſt from the abdomen; and unmarried women, when they faint at meals, give too much cauſe to ſuſpect this to be the caſe with them. Some people who are paſſionate, and ſuppreſs violent fits of it while at their meals, fall into faintings alſo.

The ſymptomatic *lipothymy* is a very common diſorder, and ariſes from a great number of different cauſes. Women who have ſuppreſſion of the menſes are very frequently ſubject to it. People fatigued with violent emetics alſo often fall into it, as do alſo perſons exhauſted by violent hæmorrhages, by profuſe ſweats, diarrhœas, violent pains of any kind, and by want of food. People, on the contrary, who are very voracious, and load the ſtomach with great quantities of food as often fall into it; and women after hard child-birth, or too great a flux of the lochia, are very ſubject to it. People who have taken poiſons, and ſuch as have taken violently cooling medicines alſo ſometimes are ſubject to it; and thoſe, who in fevers, ſuddenly cool themſelves, and check their ſweats, or who once load the ſtomach with great quantities of food immediately after recovering from illneſſes. The approach of epidemical malignant fevers is often preſaged by faintings; and finally, people are ſometimes ſubject to them from omitting any cuſtomary evacuations.

Prognoſtics in it. An idiopathic *lipothymy*, which happens in healthy, but very tender and ſenſible, or melancholic perſons, and has had a fright, or ſome other paſſion for its origin, is a thing of no great conſequence for the preſent; but it is apt to grow upon people if not taken care of, and they will be perhaps always ſubject to it afterwards. *Lipothymies*, when ſymptomatic, are of much more conſequence. In chronic diſeaſes they are leſs dangerous ſymptoms than in acute ones, if attended with faintings in the beginning; for theſe often prove dangerous. In other ſtages of acute diſeaſes, faintings are always bad ſymptoms; but when they are owing to the ſuppreſſion of ſome habitual excretion, during the courſe of the diſeaſe, they are of leſs danger than when they appear without ſuch cauſes. All faintings that attend other diſeaſes are however to be regarded only as ſymptoms, not treated diſtinctly; and when the diſtemper which occaſioned them goes off, they naturally follow it. Syncopes that often return upon a perſon, and continue for a long time, frequently leave fevers behind them. Syncopes from hæmorrhages are often dangerous, eſpecially in perſons not accuſtomed to them, and to ſuch as are of a timid diſpoſition; whence women in child-bed, who are ſubject to faint, are to be carefully watched, for they ſometimes die in theſe fits.

Method of cure. In idiopathic *lipothymies*, ſtimulating glyſters, the ſprinkling of cold water upon the face, and the penetrating ſmells, ſuch as thoſe of the volatile ſalts, ſpirit of hartſhorn, free air, and Hungary-water, all tend to recover the loſt motion. To theſe are to be added undreſſing, or looſening the cloaths, lying down in a warm bed, frictions, ſternutatory powders, and the laying a little pepper, or a ſmall morſel of ſome pungent volatile ſalt upon the tongue. The hands and face ſhould alſo be ſprinkled with vinegar; and the patient ſhould have a ſpoonful or two of water, if he can ſwallow, with about a third part of vinegar mixed with it poured into his mouth: if theſe ſhould not remove the complaint, it will be neceſſary to bleed the patient and to give him a clyſter: but with reſpect to perſons who are weak and delicate, and ſubject to nervous diſorders, bleeding is dangerous; perſons who faint in cloſe rooms ſhould be immediately carried into the open air; their temples ſhould be rubbed with ſtrong vinegar, or brandy, and volatile ſpirits or ſalt held to the noſe. They ſhould be laid on their backs with their head low, and have a little wine or other cordial poured into their mouths, as ſoon as they are able to ſwallow it. If they have been ſubject to hyſteric fits, caſtor or aſſa-fœtida ſhould be applied to the noſe, or burnt feathers, horn, or leather &c. After the patient is, by theſe means, brought to himſelf, a glaſs of warm wine, with ſome tincture of ſaffron, is very proper to recruit the ſtrength; and if there be danger of a fever coming on, that is to be guarded againſt, by giving powders of mirre, crabs eyes, diaphoretic antimony, and a little cinnabar. In caſes where faintings happen from an undue repletion of the ſtomach, or from a weakneſs of the primæ viæ, with crudities lodged there, and attended with eructations, the uſe of digeſtive medicines is proper; and vomits ſhould be now and then given with them. When the faintings happen from the violence of emetic medicines, burnt wine, with the ſpices, is to be taken occaſionally in the day-time, and a moderate doſe of the theriaca at night. When faintings have been brought on by violent paſſions, the patient ſhould be ſuffered to remain at reſt, and made to ſmell to ſome vinegar: after he is come to himſelf, he may drink freely of warm lemonade, or balm tea, with ſome orange or lemon put in it. If the fainting fits have been long and ſevere, the ſtomach and bowels may be cleanſed by a vomit or an emollient clyſter; and when the operation of theſe is over, the nitrous and abſorbent medicines ſhould be given for a day or two, to prevent a fever, which often attends faintings from ſuch cauſes. When they happen to people exhauſted by repeated hæmorrhages, or by diarrhœas, profuſe ſweats, or other evacuations, the analeptics are the proper medicines to carry them off, and reſtorative electuaries, with coral and the like, are to be given; and the frequent eating of jellies, nouriſhing broths, ſago gruel with wine, new milk, and other things of a light and cordial nature recommended by way of prevention. All that can be done in the fit is to let the patient ſmell to a boule of Hungary-water, eau de luce, or ſpirits of hartſhorn; to rub his temples with brandy, or to lay a compreſs dipped in it to the pit of the ſtomach. The crudities of the primæ viæ muſt be cleared off by digeſtives and purging medicines; the mind muſt be unbent from ſtudy, and kept free from the violence of all paſſions; the neceſſary and habitual excretions muſt be, by all means, promoted; and the patients ſhould always have ſalts, and volatile ſpirits about them, to uſe on occaſion of being threatened with a fit. Finally, moderate exerciſe is always to be adviſed. In the time of the fit ſtimulating glyſters are never to be given, before it has continued a quarter of an hour; and in general, where there remains any ſign of life, they are not neceſſary; and during the time of the fit, an internal medicine muſt be given with the greateſt caution; for they are apt to paſs into the aſpera arteria. People, juſt recovered out of a fainting fit, are not to be ſuffered to ſleep, if they ever ſo much deſire it; and after the paroxyſm is thoroughly over, a chearfulneſs of temper will do more towards a thorough cure, and the prevention of returns, than all the medicines in the world. If a fever comes on immediately after the fainting, then the uſe of a glaſs of wine, ſo beneficial on all other occaſions of this kind, is not to be allowed, but recourſe is immediately to be had to antifebrific medicines. Vomits are very proper in faintings occaſioned by paſſion or terror, in the time of eating a hearty meal, or immediately after it; for it is much better that the food ſhould be thrown up undigeſted, than remain ſo in the ſtomach.

Many people are ſubject to faintings after bleeding; in this caſe the arm ſhould be but gently tied up, and they ſhould never be blooded after a full meal, nor get up immediately after the bleeding is over.

It is very obſervable, that in faintings ariſing from a preſent cauſe, as in the laſt mentioned article of bleeding, the patient has as at firſt ſome power of motion, though on a confuſed principle, and will often, before he faints, violently attempt to prevent the ſurgeon from tying up the arm; but in thoſe faintings, which are preſages of future miſchief, the patient always falls down at once to the ground, and has no power of motion, or ſenſe of it, in its approach. Junker's Conſp. Med. p. 673, and Buchan's Dom. Med. p. 479.

LIPPIA, in *Botany*, a genus of the *didynamia angioſpermia* claſs. Its characters are theſe: the empalement of the flower is permanent, roundiſh, compreſſed, and divided into four notches; the flower hath one petal, which is of the ringent kind; and hath four ſhort ſtamina, two of which are longer than the other; and oval germen, which afterward turns to a compreſſed capſule with one cell, opening with

with two valves, which appear like the scales of the empalement, inclosing two seeds which are joined. Linnæus enumerates three species of this plant.

LIPPITUDO is used, by Celsus, for a disease in the eyes, otherwise called ophthalmia.

LIPPITUDO is also used, by modern writers, for a disorder popularly called *blear-eyed*, arising from a decay of the natural moisture of the eyes, which then feel dry, and appear red and angry. See SCLEROPHTHALMIA.

LIPS, *labia*, the edge, or exterior part, of the mouth; or that musculous extremity which shuts and covers the mouth, both above and below.

The *lips*, besides the common integuments, consist of two parts: the *exterior*, hard and musculous; the *interior*, soft, spongy, and glandulous, covered with a fine membrane, which seems to be both a continuation of the epidermis, and of that pellicle which covers the glandulous membrane of the cavity of the mouth, the fore and protuberant parts of which are red, and called *prolabia*; the substance that forms these parts being a collection of very fine, long, villous papillæ, is extremely sensible, and very painful, when the outer membrane is by any accident destroyed. The internal membrane of the upper *lip* forms a small middle FRÆNUM, above the first dentes incisorii. Authors generally content themselves with calling the substance of the prolabia, spongy; but, in reality, it is glandulous, as appears by the scrupulous and cancerous humours to which it is subject. The muscles, of which the outer parts of the *lips* consist, are either *common* to them with other parts, or *proper* the common are, the *semi-orbicularis*, of which the superior is often broader than the inferior, having also this peculiarity, that all its fibres do not go to the corner of the mouth, but terminate by degrees between the middle and the extremities of the arch of the *lip*, nearly like the semi-oval fibres of the upper palpebræ; but the inferior is commonly more uniform in the disposition of its fibres; the *supra-semi-orbicularis* being fibres, which increase the breadth of the two lateral portions of the superior semi-orbicularis upward; the BUCCINATORES, which are two in number, each of them situated transversely between the posterior part of the two jaws and the corner of the mouth; and the ZYGOMATICI *majores*, which are two muscles situated, one on each side, between the zygoma and the corner of the mouth. The upper *lip* has four pair of proper muscles, viz. the *zygomatici minores*, which are two small slender muscles, lying above the great *zygomatici*, and almost parallel to them; the two *caninæ*, each of which is fixed by a broad insertion in the upper jaw, above the socket of the *dens caninus*, in a depression below the inferior edge of the orbit, near the *os malæ*, running down from thence a little obliquely, and crossing the lower extremity of the *zygomæus major*, which covers it at this place; and terminating at the extremity of the arch of the semi-orbicularis superior, and communicating by some fibres with the triangularis; the *incisorii laterales*, each of which is a sort of biceps, its upper part being divided into two portions, which unite below; and the *incisorii medii*, which are two small short muscles situated near each other, below the septum narium. The proper muscles of the lower *lip* are four pair; viz. the *triangulares*, each of which is fixed by a broad extremity in the outside of the basis of the lower jaw, from the masseter to the hole near the chin, seeming to be a continuation of the caninus major; the *triangularium collateralis*; the *incisorii inferiores*, each of which is fixed by the superior extremity on the alveoli of the lateral incisores of the lower jaw; and the *cutanei*, forming a kind of fleshy membrane, that covers the whole foreside of the throat and neck, from the cheek and chin, all the way down below the clavicles; besides the *quadratus*, which forms the thick part of the chin, below the under *lip*. The common muscles of the *lips* either draw both the corners of the mouth at once, or only one at a time, according to the different direction of their fibres. The proper muscles pull the different parts of the *lips*, in which they are inserted; the buccinators, in particular, may serve to move the food in mastication. Winslow. See ATTOLLENS, DEPRIMENS, and DEPRESSOR *labiorum*, ZYGOMATICUS, ORBICULARIS, &c.

All these parts are served with blood by some branches of the carotids, which the veins carry back to the external jugulars. Their nerves come from the fifth, sixth, and eighth pair of the head, and some from the *par accessorium*. The *lips* have a great share in the action of speech, and are of good use in taking in the food, &c.

Hare-LIP, a disorder, in which the upper *lip* is in a manner slit or divided, so as to resemble the upper *lip* of a hare; whence the name.

Sometimes the division is so large, that it appears as if part of the *lip* was wanting; and sometimes again the division is double. A like fissure is also sometimes made in the lower *lip* by a wound that has been neglected, or improperly treated: this last species of the disorder is termed the spurious *hare-lip*; the true kind is born with the infant. The less and more equal the fissure of the *hare-lip* is, it is generally so much the more easily cured. In some infants, the division of the *lip* is so large and irregular, that there can be but little hopes of a cure, which may, however, be easily performed on the very same *lip*, when adult. Sometimes too we meet with a tooth projecting forward into the fissure; in this case it cannot be cured, without taking out the tooth. In a recent *hare-lip*, or one made by a wound, the cure is to be performed by the knotted future. See *Interrupted* SUTURE, and WOUND.

In curing the *hare-lip*, where part of the *lip* is wanting, no attempt can be made to supply what is deficient, but only to unite those parts which are divided; by taking off the skin from the edges of the fissure, and then causing them to unite and grow together, by passing through them two or three needles, made of gold or silver, pointed with steel, from the right to the left, beginning with the upper part of the fissure, and inserting them at about a straw's breadth from each other. The surgeon having thus entered the needle, and cleansed the bleeding *lips* with a spunge, he takes a piece of strong waxed thread or silk, and fastening it about one end of the needle, he winds it over the other end, and back again, and afterwards secures it by a knot; by this means the edges of the *lips* are brought close together, and the upper part or surface kept smooth and even. To heal the wound internally, it is dressed with soft lint, dipped in honey of roses, and put between the gums and *lip*; but this practice can only be followed with adults; the external part of the wound is at the same time dressed with balsam of Peru, or some other vulnerary unguent, covered with lint and compress, and over that a sticking plaster, with four heads, two of which are fastened on the left side of the *lip*, and two upon the right, and the whole secured by a sling or fillet. Whose extremities may be fastened about the head, either by a knot or pins. But it must here be observed, that when the fissure appears large and deep, so that the two parts of the *lip* cannot be easily joined, it will be necessary, before the above operation, to divide the frenulum of the upper lip from the gum, with a pair of scissars, but without wounding the gum, or uncovering the jaw. Though the hæmorrhage is often very plentiful in performing these operations on young infants, yet it is not dangerous, since it prevents an inflammation, and generally ceases after tying the bandages.

The dressings ought not to be moved before the third day, unless some accident makes it necessary: and then it must be done with great caution, to avoid separating the parts in contact. If the *lips* of the wound appear conjoined, three or four days after the operation, you may then venture to draw out the middle needle, when there are three, or the upper one, when there are only two; and two or three days after draw out the other: the cure must be completed, by dressing every day as at first.

LIPS, *wounds of*. Wounds of the *lips* are made either with sharp or with blunt instruments, or else with bullets. Those of the first sort, whether longitudinal or transverse, are generally to be cured by the dry future. The patient, while under cure, must avoid talking and chewing; his diet therefore must be spoon-meat. But in cases where the wound is very large, the bloody future is sometimes necessary. In wounds of the *lips* made by blunt instruments, by falls, or by bullets, the shattered parts must be brought to digestion; and the *lips* of the wound, after being cleaned, brought together, either by means of sticking plasters, or by the future used in the *hare-lip*. Heister's Surg. p. 81.

LIPS, *cancer of the*. See CANCER.

LIPS is also applied to the two extreme parts of the *pudendum muliebre*; between which is the *rima*, or fissure of the part.

These are more peculiarly called *labia pudendi*; being soft, oblong bodies; of a peculiar substance, not found in any other part of the body.

LIPS are also used to signify the two edges of a wound.

LIPTOTES, in *Rhetoric*, a figure, wherein, by denying the contrary of what we intend, more is signified than we would seem to express. Thus in the following verse of Virgil.

Quid precibus, quod me ipse animo non sperni, Amynta?

See Vossius, Rhet. lib. iv. p. 183.

LIPYRIA, a name given by some medical writers to a dangerous species of fever, in which the outside of the flesh is cold, while the inside is very hot.

LIQUAMEN *spirituum*, in *Natural History*, a name given by some authors to the liquid matter remaining in the pans in which the common vitriol is made; after which no more of that salt will shoot. It is otherwise called *liquamen of* VITRIOL.

LIQUAMUMIA, a term invented by some of the dispensatory writers, to signify human fat.

LIQUEFACTION, an operation, by which a solid body is reduced into a liquid; or the action of fire or heat on fat, and other fusible bodies, which puts their parts into a mutual intestine motion.

The *liquefaction* of wax, &c. is performed by a moderate heat; that of fal tartari, by the mere moisture of the air. All fats liquefy; and, mixed with alkalies, becomes inodorated by a very laborious fire, in the making of CASTILE soap.

In speaking of metals, instead of *liquefaction*, we ordinarily use the word FUSION.

LIQUET. See NON LIQUET.

LIQUID, a body which has the property of fluidity; and, besides that, a peculiar quality of wetting other bodies immerged in it, arising from some configuration of its particles, which disposes them to adhere to the surfaces of bodies contiguous to them. See FLUID.

LIQUIDA, *gravity of*. See DENSITY.

LIQUIDAMBAR, AMBER, *ambrella*, *liquidum*, *succiferæ*, *storax*, *gummi*. See the respective substantives.

LIQUID, among *Grammarians*, is a name applied to certain consonants opposed to *mutes*.

L, *m*, *n*, and *r*, are *liquids*. See L, M, N, &c.

LIQUID *amber*, in *Botany*, *sweet gum*, a genus of the *monœcia polyandria* class. Its characters are these: it hath male and female flowers on the same tree; the male flowers are disposed in long, loose, conical catkins; these have four-leaved empalements, no petals, but a great number of short stamina joined in one body; the female flowers are situated at the base of the male spike, collected in a globe, and have a double empalement; they have no petals, but an oblong germen fastened to the empalement, which turns to a roundish capsule of one cell, with two valves at the top, which are collected in a ligneous globe, containing many oblong acute pointed seeds. There are two species.

LIQUIDATE, *to*. See ACTION.

LIQUIDATION, the act of reducing and ascertaining either some dubious disputable sum, or the respective pretensions which two persons may have to the same sum.

LIQUOR. See DRINK, FLUID, &c.

LIQUORS, *fermented*. See FERMENTED *liquors*.

LIQUORS, *red*, among the *Dealers in Brandy*. See SPIRIT and TEST-*liquors*.

LIQUOR *anodynus mineralis*, the name given by Hoffman to a *liquor* of his own invention, famous at this time in Germany, and supposed by Sprengrave to be made in this manner: take oil of vitriol and Indian nitre, of each four ounces; diſtill the ſpirit gradually from this by a retort; pour two ounces of this ſpirit cautiouſly and ſucceſſively into fifteen ounces of ſpirit of wine highly rectified; diſtill this, and there comes over a very fragrant ſpirit. This is to be again diſtilled, to render it perfectly pure, adding ſalt to it a ſmall quantity of oil of cloves, and a quantity of water, equal to that of the ſpirit; after this, as ſoon as the watery vapours begin to ariſe, the whole proceſs is to be ſtopped, and the ſpirit kept alone in a bottle well ſtopt. This has great virtues, as an anodyne, diaphoretic, antiſeptic, and carminative. It is not certain that it is exactly the ſame with Hoffman's, that author having never publiſhed his manner of making it; but it appears the ſame to the ſmell and taſte, and has the ſame virtues.

M. Macquer ſays, that it is a mixture of very rectified ſpirit of wine, of æther, and of a little of the ſweet oil of vitriol; and that it is made by mixing an ounce of the ſpirit of wine, which riſes firſt in the diſtillation of æther, with as much of the *liquor* which riſes next, and which contains the æther, and afterwards by diſſolving in the mixture twelve drops of the oil which riſes after the æther has paſſed. This *liquor* has preciſely the ſame virtues with the æther, which phyſicians now ſubſtitute for it. See ÆTHER.

LIQUOR *of flints*. See FLINTS.

LIQUOR, or *ſmoking ſpirit of Libavius*, is a marine acid, very concentrated, ſmoking, and impregnated with nitre ſpirit. It is made by well mixing an amalgam of four parts of tin and five parts of mercury with an equal weight of corroſive ſublimate, by triturating the whole together in a glaſs mortar. This mixture is to be put into a glaſs retort, which is to be placed in a reverberatory furnace. To the retort is to be luted, with fat lute, a receiver, with a ſmall hole in it, in the ſame manner as is done for the diſtillation of concentrated mineral acids; the diſtillation is begun with a gradated and well managed fire. A very ſmoking *liquor* paſſes into the receiver, and towards the end of the diſtillation a very thick and even concrete matter. When the operation is finiſhed, the *liquor* in the receiver is to be poured quickly into a cryſtal glaſs bottle, with a glaſs ſtopper. When this bottle is opened, a white, copious, thick, and poignant fume iſſues, which remains long in the air without diſappearing. Chem. Dict. See ÆTHER.

LIQUORS, *Stygian*. See STYGIAN *liquors*.

LIQUORS, *clearing of*. See CLARIFICATION.

LIQUORICE, *Liquiritia*, in *Botany*, a genus of the *diadelphia decandria* class. Its characters are these: the flower has a permanent empalement of one leaf, divided into two lips; the flower is of the butterfly-kind, having a long erect ſtandard with oblong wings, and a two-leaved keel, which is acute; it has ten ſtamina, nine joined, and one ſtanding ſingle; in the bottom is ſituated a ſhort germen, which becomes an oblong or oval compreſſed pod with one cell, including two or three kidney-ſhaped ſeeds. There are three ſpecies.

The common *liquorice* is a plant propagated in many parts of England to very great advantage. It delights in a rich light ſandy ſoil, which ſhould be three feet deep at leaſt; for the greateſt advantage conſiſts in the length of the roots. The greateſt quantities of it propagated in England are about Pontefract in Yorkſhire, and about Godalming in Surry; though there is no inconſiderable quantity propagated in the gardens about London.

The ground deſigned for *liquorice* muſt be well dug, and dunged the year before, that the dung may be thoroughly rotted in it; and juſt before it is planted, the earth is to be dug three ſpades deep, and laid very light. The plants to be ſet ſhould be taken from the ſides or heads of the old roots, and each muſt have a very good bud, or eye, otherwiſe they are very ſubject to miſcarry; they ſhould alſo be about ten inches long, and perfectly ſound. The beſt ſeaſon for planting them is the end of February, or the beginning of March, and this muſt be done in the following manner: the rows muſt be marked by a line drawn across the bed, at two feet diſtance, and the plants muſt be ſet in theſe by making a hole of their full depth and ſomething more, that the eye of the root may be an inch below the ſurface: they muſt alſo be ſet at two feet diſtance from each other in each row. When this is done, the ground may be ſowed over with onions, which not rooting deep, will do the *liquorice* roots no injury for the firſt year. In October, when the ſtalks of the *liquorice* are dead, a little very rotten dung ſhould be ſpread over the ſurface of the ground. Three years after the time of planting, the *liquorice* will be fit to take up for uſe; and this ſhould be done juſt when the ſtalks are dead off; for if taken up ſooner, the roots are very apt to ſhrink greatly in their weight. The roots about London look browner than thoſe which have been propagated in a leſs rich ſoil; but then they are much larger, and grow quicker to their ſize. Miller.

New green *liquorice* ſhould be chooſen ſmooth and even, about the thickneſs of the middle-finger, ſtudy without, yellowiſh within, eaſy to cut, and of an agreeable ſmell. The root carefully dried and powdered is of a richer and more agreeable taſte than when freſh, and of a full yellow colour, with a caſt of brown. The *liquorice* powder commonly ſold is of a weaker taſte, and a paler and lighter yellow colour, probably from a mixture of other ſubſtances.

This root being lightly boiled in water, till the fluid has acquired a deep yellow tincture, and the water at length evaporated over a moderate fire, there remains a black, ſolid ſediment, of a pleaſant ſmell, of a dark reddiſh brown colour in the maſs, and, when drawn out into ſtrings, of a golden colour, which we alſo call *liquorice*, or *liquorice juice*, or ſometimes *Spaniſh juice*. Its quantity amounts to near half the weight of the root. Long boiling impairs the ſweetneſs of the juice, and gives it an unpleaſant bitterneſs.

The whitiſh and yellowiſh *liquorice* juices are good for nothing, being uſually no other than compoſitions of ſugar, ſtarch, a little gum tragacanth, and *liquorice* powder.

The *liquorice* root yields its ſweetneſs alſo to rectified ſpirit; but the quantity of ſpirituous extract amounts only to about one half of the aqueous; and rectified ſpirit, digeſted on the aqueous extract, diſſolves about one half of it.

The native *liquorice* juice is very ſweet upon the palate, even more than ſugar, or honey; and is yet accounted a great quencher of thirſt; on which account Galen preſcribes it in dropſies. It is very balſamic and detergent; inſomuch that there is ſcarce any medicinal compoſition for diſeaſes of the breaſt, in which it is not an ingredient.

LIQUORICE, *ſcotch*. See *Bitter* VETCH.

LIQUORICE, *wild*, *Liquorice* VETCH, or *Milk* VETCH, *aſtragalus*, in *Botany*. See ASTRAGALUS. See alſo CAPRARIA.

LIQUORICE-*wood*, *knobbed-rooted*. See GLYCINE.

LIRIODENDRUM, in *Botany*. See TULIP-*tree*.

LISIAN-

LISIANTHUS, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are, that the flower is encompassed by a kind of ventricose tube, with recurved segments; the empalement is heel-shaped: the stigma has two lobes: and the fruit is an oblong capsule, with two cells. There are two species.

LISSA, or THYNNUS LESSA, in *Zoology*, a name by which some authors have called the fish more usually called *glissa*, a large sea-fish of the tunny kind.

LIST, in the *Manufactures*, denotes the border of a stuff, or that which bounds its width on each side.

Du-Cange derives the word from *licia*, which, in the age of corrupt Latin, was used for the inclosures of fields and cities, as being anciently made with cords interlaced; or from *lista, area campum circumdans in quo decertant pugiles*; as including the ground about the manner that a *list* does a piece of cloth.

All cloths, and stuffs of silk, wool, or cotton, have *lists*. *Lists* contribute to the goodness of the stuff, and farther serve to shew their quality; which has given occasion to several regulations relating to their matter, colour, work, &c.

LIST is also used to signify the inclosed field, or ground, wherein the ancient knights held their justs and combats. It was so called, as being hemmed round with pales, barriers, or stakes, as with a *list*.

Some of these were double, one for each cavalier; which kept them apart, so that they could not come nearer each other than a spear's length. See TOURNAMENT, and DUEL.

LIST, LISTEL, or LISTELLO, in *Architecture*, called also CINCTURE, FILLET, SQUARE, and REGLET, is a little square moulding, serving to crown or accompany larger mouldings; and, on occasion, to separate the flutings of columns.

LIST, in the *Sea Language*, the same with LURY.

LIST, *civil*. See CIVIL *list*, and REVENUE.

LISTENING, according to Robault, consists in extending or bracing the tympanum of the ear, and putting it into such a condition, as that it shall be the more affected by any tremulous motion of the external air. See EAR.

LISTENING, in the *Manege*, as when we say a horse goes a *listening* pace. See ECOUTE.

LISTENING *trumpet*. See TRUMPET.

LISTING, or INLISTING, in *Military Language*, denotes the retaining and enrolling soldiers, as volunteers, for the national service. When any person is *inlisted* as a soldier, he shall within four days be taken before the next justice of peace, or chief magistrate of a town; and before him shall be at liberty to declare his dissent to such *inlisting*; and on such declaration, and returning the *inlisting* money, and paying 20s. for the charges expended on him, he shall be forthwith discharged, in presence of such magistrate. But if he shall refuse or neglect in twenty-four hours to return and pay such money, he shall be deemed to be *inlisted*, as if he had given his assent before the magistrate. If he declare that he voluntarily *inlisted* himself, the magistrate shall certify under his hand, that such person is duly *inlisted*, setting forth the place of his birth, age, and calling, if known; and that the second and fifth sections of the articles of war against mutiny and desertion were read to him, and that he has taken the oath mentioned in the said articles of war; and if any person so certified as duly *inlisted* shall refuse to take the said oath of fidelity before such magistrate, the officer, from whom he hath received such money, may detain and confine him till he shall take it; and every military officer that shall herein offend, shall be cashiered and displaced from their office, and disabled from holding any military post, and forfeit 50*l*. See FORFEITURE *service*.

LITANY, an old church term, applied to the processions, prayers, and supplications, used for appeasing the wrath of God, averting his judgments, or procuring his mercies.

The word comes from the Greek λιτανια, *supplicatio*; of λιτανευω, *I beseech*. Perion would go farther, and derive the λιτανια, or λιτανευω, of the Greeks, from the Celtic *lit*, *fault*, *calamity*.

Ecclesiastic authors, and the Roman order, by the word *litany* usually mean the people who compose the procession, and assist at it: and Du-Cange observes, that the word anciently signified PROCESSION.

Simeon of Thessalonica mentions, that, in the ancient *litanies* the people went out of the church, to denote the fall of Adam; and returned into it again, to shew the return of a pious soul to God, by repentance.

LITANY, in a modern sense, denotes a form of prayer, sung or said in churches; consisting of several periods, or articles; at the end of each whereof is an invocation in the same terms.

Before the last review of the common prayer, the *litany* was a distinct service by itself, and used some time after the morning prayer was over. At present it is made one office with the morning service, being ordered to be read after the third collect for grace, instead of the intercessional prayers in the daily service.

LITCHI, in *Botany*, the name of an Oriental fruit very common in China, and greatly esteemed by the Chinese. They say it is of the exact middle temperature between hot and cold, and that, beyond all other vegetables, it gives vigour and strength to the body; they also commend it for the gravel, when properly prepared. This is a fruit that must be nicely watched, to find the time of its ripening, and when that comes it must be gathered, for it soon decays.

LITE, the name of a plaster much commended by the ancients: it consisted of verdegrise, wax, and resin. Whatever virtues this plaster possessed, might be probably found in the meanest plaster of the shops in general, and the late reformation made by the London Pharmacopœia, the virtues being generally given by our wholesale dealers with verdegrise, and not with the juice of the herb from which it took its name.

LITERÆ *communicatoriæ*, in *Church History*, letters granted by the bishops to penitents, when the time of their penance was finished, by which they were again received into the communion of the faithful.

LITERAL *degree*. See ALGEBRA.

LITERAL *chandler*. See CHARACTER.

LITTERALIS *calculus*. See CALCULUS.

LITERARY *property*, is that property which an author, or his assignee, may be supposed to have in his own literary compositions; so that no other person without his leave may publish or make profit of the copies. In case of a bargain for valuable consideration, or a free gift of the copy right, the retention is plainly contained in the original proprietor, or the whole property is transferred to another. It has been a question much agitated of late in the superior courts of judicature, and at length determined by the house of lords against authors and their assignees, whether the copyright of a book belongs to the author by common law. But, exclusive of such copyright as may subsist by the rules of the common law, the statute 8 Ann. cap. 19 has protected by additional penalties, the property of authors and their assigns for the term of fourteen years, and hath directed, that if, at the end of that term, the author himself be living, the right shall then return to him for another term of the same duration: and this is the sole right now vested in the proprietors of copies. A similar privilege is extended to the inventors of prints and engravings, for the term of twenty-eight years, by 8 Geo. II. cap. 13. and 7 Geo. III. cap. 38.

LITERARY *criticism*. See CRITICISM.

LITERATI, *learned*, lettered, an epithet given to such persons, among the Chinese, as are able to read and write their language.

The *literati* alone are capable of being made mandarins.

LITERATI is also the name of a particular sect, either in religion, philosophy, or politics; consisting principally of the learned men of that country; among whom it is called *jukiau*, i. e. *learned*.

It had its rise in the year of Christ 1400, when the emperor, to awaken the native affection of the people for knowledge, which had been quite banished by the preceding civil wars among them, and to the ap emulation among the mandarins, chose out forty-two of the ablest among their doctors, to whom he gave a commission to compose a body of doctrine, agreeable to that of the ancients, which was then become the rule, or standard, of the learned. The delegates applied themselves to the business with very great attention: but some fancied them rather to have wrested the doctrine of the ancients, to make it consist with their's, than to have built up their's on the model of the ancients.

They speak of the Deity, as if it were no more than mere nature, or the natural power or virtue that produces, disposes, and preserves the several parts of the universe. It is, say they, a pure, perfect principle, without beginning or end; it is the source of all things, the essence of every being, and that which determines it to be what it is. They make God the soul of the world: they say, he is diffused throughout all matter, and produces all the changes that happen there. In short, it is not easy to determine, whether they resolve God into nature, or lift up nature into God; for they ascribe to it many of those things which we attribute to God.

This doctrine, in lieu of the idolatry that prevailed before, introduced a refined kind of atheism. The work, being composed by so many persons of learning and parts, and approved by the emperor himself, was received with infinite applause by all the people. Many were pleased with it, because it seemed to subvert all religion; others approved

proved it, because the little religion that it left them, could not give them much trouble. And thus was formed the sect of the *Literati*; which consists of the maintainers and adherents to this doctrine.

The court, the mandarins, and the persons of fortune and quality, &c. are generally retainers to it; but a great part of the common people still hold to their worship of idols.

The *literati* freely tolerate the Mahometans, because they adore, with them, the king of heaven, and author of nature; but they bear a perfect aversion to all sorts of idolaters among them: and it was once resolved to extirpate them. But the disorder this would have occasioned in the empire prevented it: they now content themselves with condemning them, in general, as heretics; which they do solemnly every year at Pekin.

LITHAGOGI, of λιθος, *stone*, and αγω, *I bring away*, an epithet given by some medical writers to such medicines as work by urine, and are supposed to have the virtue of expelling the stone.

LITHANTHRAX, of λιθος, *stone*, and ανθραξ, *coal*, in *Natural History*, is used as the name of the common pit coal. See COAL.

LITHARGE, composed of λιθος, *a stone*, and αργυρος *silver*, a metalline substance, formed of the spume of lead; used in the composition of plasters, to give them a due consistence: for, it is lead deprived of great part of its phlogiston by fire, and in a state of imperfect vitrification.

This preparation of lead is of great use in roasting the stubborn ores of gold, silver, and copper; for it melts all kinds of stones and earth into glass, sooner than the metals; and by this means the metal, which is heavier, will fall through the glass, which is a thin and light substance, and will be collected under it into a regulus, with only a few dusty scoriæ adhering to it. But if it be copper that is thus separated, a small portion of it is always destroyed; and if gold or silver, a like small portion is always lodged and detained in the scorie.

But as the *litharge* penetrates through all sorts of vessels, and while melting rises into a scum, that often runs over their edges, the assayers never use it alone, but always mix with it such substances as may give it a clamminess, such as flints, sand, clay, or the like: they mix two parts of *litharge* with one part of any of these substances, and add some nitre, or common salt, that the whole may run the more easily. They shut up the vessels, which must be made very thick and solid, with a small cover or lid, cut close, and placing this in a wind-furnace, they keep it in fusion a quarter of an hour, looking at times into the ash-hole, to see if the glass have not escaped through the vessel, and run down thither. Very often it is found sweating through the sides of the vessel, like water, and falling in drops into the ash-hole; and in this case, there is no way to preserve the remainder, but to take the vessel out of the fire.

When the whole is cool, the vessel must be broke, and at the bottom there will be found a small quantity of a regulus of lead, revived by means of the salt; in the middle, the glass of lead, which must be kept for use; and at the top a saline crust, which is to be thrown away.

Some authors speak of two kinds of *litharge*; the one *natural*, the other *artificial*.

LITHARGE, *natural*, they say, is a mineral, sometimes found in lead mines, reddish, scaly, brittle, and somewhat resembling white-lead. This *litharge* is so exceeding rare, that the shops sell none but the

LITHARGE, *artificial*, which is of two kinds; viz. that *of gold*, and that *of silver*; or rather, it is the same, with this difference, that the one has undergone a greater degree of fire than the other.

Indeed naturalists are not very well agreed what the *artificial litharge* is: some consider it as a metallic scum, called on the surface of lead, when melted; after having served to purify gold, silver, or copper.

Others consider it as a metallic soot, or smoke, arising from those metals mixed with the lead used in purifying them; which, sticking to the top of the chimneys of furnaces, is there formed in a kind of scales.

Lastly, Others consider it as the lead itself used in refining of those metals, and especially copper; which last opinion appears the most credible: and the rather, on account of the great quantities of these *lithargers* brought from Poland, Sweden, and Denmark; where copper mines are much more frequent than those of gold and silver. The drossy or recrementitious parts, rising to the face of the ore, are the *litharge*; and, according to the degree of calcination, become of divers shades of a red colour: the deep is called *litharge of gold*, and the pale, *litharge of silver*.

Litharge may be easily revived into lead; accordingly, much of that which is produced by refining in great is reduced, by being melted upon burning coals. The part which is least altered by mixture with other metals is thus reduced, and thus good and saleable lead is obtained. The rest of the *litharge* of these refineries is sold and used for various purposes.

Lithargers are deficcative, detersive, and cooling: they make the consistence of several plasters. The potters use them to give a beautiful gloss to their ware; they are employed in the composition of some glasses, for they are very fusible, and assist the fusion of other substances; and they are also used by painters, dyers, skinners, and glaziers. When mixed with wine, they give it a bright sprightly colour, but render it extremely unwholesome. See LEAD.

LITHARGE, *plaster of*. See EMPLASTRUM *commune*.

LITHARGE, *vinegar of*. See VINEGAR *of Lead*.

LITHIASIS, λιθιασις, in *Physic*, the disease of the stone. See STONE and CALCULUS.

LITHIDIA, in *Natural History*, the name of a large class of fossils, including the flint and pebble kinds.

The *lithidia* are defined to be stones of a debased crystalline matter, covered by, and surrounded with an opake crust, and frequently of great beauty, and considerable brightness within, though of but a slight degree of transparence, approaching to the nature of the semipellucid gems, and like them found not in very large masses.

The bodies of this class are divided into two general orders, and under those into three genera. The first order of the *lithidia* contains those composed of a crystalline matter, but slightly debased, and that ever by one and the same earth, though diffused through them in different degrees, and always free from veins. The second order comprehends those of a more debased crystalline matter, blended with different portions of differently coloured earths. Of the first of these orders there is only one genus, which is that of the common FLINT.

Of the second order there are two genera. 1. The MOCHOIDES, which are of one plain and simple colour; and, 2. The *calculi*, which are composed of crusts of several different colours. Both these genera are comprised under the common English names of PEBBLES. Hill's Hist. of Foss. p. 505.

LITHOBOLIA, λιθοβολια, in *Antiquity*, a festival celebrated by the Trœzenians, in memory of Lamia and Anxesia, two virgins, that coming from Crete to Trœzene, in a time of tumult and sedition, became a sacrifice to the fury of the people, by whom they were stoned to death.

LITHOBOLIA, or *lapidation*, was also a common punishment inflicted by the primitive Greeks upon such as were taken in adultery.

LITHOCOLLA, or LITHOCOLLUM, formed of the Greek λιθος, *stone*, and κολλα; *glue*, a cement used by the lapidaries to fasten their precious stones, in order for cutting them.

It is composed of resin and brick-dust. For diamonds, they use melted lead, putting them into it before it be quite cold: for other cements, they mix marble-dust with strong glue; and, to fasten their sparks, add the white of an egg, and pitch. See CEMENT.

LITHODÆMON, or LAPIS *diæmonius*, a name given by some authors to JET.

LITHODENDRON, a name by which, according to Dioscorides, many of the ancients express the common red coral.

LITHOGENESIA, a term used by some authors to express the formation and origin of STONES.

LITHOLABON, a name given by some chirurgical writers to an instrument used in the operation of lithotomy; it is a forceps intended for taking hold of the stone.

LITHOMANTIA, λιθομαντια, in *Antiquity*, a species of divination performed with stones. Sometimes the stone called *sideritis*, was used: this they washed in spring-water in the night by candle-light: the person that consulted it, was to be purified from all manner of pollution, and to have his face covered: this done, he repeated divers prayers, and placed certain characters in an appointed order: and then the stone moved of itself, and in a soft, gentle murmur (or as some say) in a voice like that of a child, returned an answer. By a stone of this nature, Helena is reported to have foretold the destruction of Troy.

LITHOMARGA, *stone marle*, a name given by some authors to a spurry substance highly debased by earth, which is found in great plenty in the caves of the Hartz Forest in Germany, and used there in medicine, under the name of the *nucleus fossilis*, or fossile unicorn's horn, from its sometimes emulating that figure. See *Mineral* AGARIC.

LITHONTRIPTICON *Tulpii*, the name of a famous diuretic medicine, invented by Tulpius, and given with great success in cases of the stone, but requiring great judgment and caution in the administering it.

The preparation is this: take a drachm of cantharides without

without their wings, and 3 drachm of leſſer cardamoms without their huſks, powder them fine, and pour upon them an ounce of rectified ſpirit of wine, and half an ounce of ſpirit of nitre: ſet them to infuſe, without heat, for five or ſix days, ſtirring them from time to time. The vial muſt not be ſtopped cloſe; becauſe, if it be, the continual fermentation will burſt it. The doſe is from fourteen to fifteen, or twenty drops, in a glaſs of wine and water. It is to be taken in a morning, an hour after eating a meſs of broth, and may be repeated for three or four days.

It is remarkable, that this mixture never ceaſes fermenting for many years; but if it be too faſt corked, will break the glaſs, if but ſlightly ſtopped, it only throws out the cork with an explosion. Mem. de l'Acad. Par. 1709. p. 358. edit. Par.

LITHONTRIPTICS, from the Greek λίθος *ſtone*, and θραύω, *I break*, medicines proper to diſſolve the ſtone in the bladder, and kidneys. See CALCULUS and STONE.

The reward which the parliament of England gave to Mrs. Stephens, the inventreſs of ſome medicines, which were ſaid to be a perfect and certain cure for the *ſtone*, made the generality of the world believe, that they were really as efficacious as they were pretended to be; but it appeared, on examination, that the opinion of a cure in the very inſtances on the ſucceſs of which the reward was given, was erroneous; and that the *ſtones* had all the time remained in the bladders of the patients, though ſuppoſed to have been pulled, after being diſſolved and waſhed away by the medicines.

The principal inſtance of a ſuppoſed cure was Mr. Gardiner. This man was, in December, 1748, examined by able ſurgeons, and found to have a ſtone in his bladder; after this he took Mrs. Stephens's medicines for eight months without intermiſſion; and at the end of that time he declared himſelf free from all his uſual complaints; and on ſearching him there could no ſtone be found in the bladder. Mr. Gardiner died about three years afterwards, and his body was opened. When the bladder was examined, there were found in it ſix preternatural apertures of different ſizes; but the largeſt capable of admitting the end of a finger. Each of theſe apertures led to a ſeparate bag formed by an enlargement of the internal membrane of the bladder, protruded between the fibres of its muſculous coat. Theſe bags were eaſily ſeen on the back part of the bladder a little above the veſicular feminales, and when viewed on the outſide, they ſeemed to be but two, though in reality equal in number to the openings within, and divided from one another by the duplicature of the internal membrane, which formed a ſeptum between each of them. Philoſ. Tranſ. N° 469. p. 12.

As to Mrs. Stephens's medicine, it is a compoſition of ſoap and lixivia made of different aſhes, which every body knows to be highly cauſtic; and is therefore condemned by Dr. Mead, ſince its corroſive quality muſt be injurious to the bladder. However, under proper management, he thinks it may be of ſome ſervice in expelling gravel by the urinary paſſages; though it will never be able to break calculi of the hardneſs of ſtone: and beſides, its long continued uſe muſt be attended with great danger, for the reaſons above given. And as for its ſubſtitute, the ſoap-leſs, though it be a medicine of a more commodious form for taking, yet it will not prove much ſafer in its conſequences, for the ſame reaſons.

Dr. White of Edinburgh, after conſidering the inconveniencies, and ſometimes the miſchiefs alſo of this celebrated ſpecific, reſolved to omit the ſoap, and try what virtues LIME-*water* might have in diſſolving the calculus. His firſt experiments were made on ſeveral fragments of calculi, with lime-water *from* the common quick-lime; and afterwards reſolved to try the power of animal-lime, he repeated them with lime-water made with oyſter-ſhells and cockle-ſhells, well calcined, by pouring ſeven or eight pints of water on one pound of the freſh calcined ſhells. The experiments ſucceeded with both ſorts; but he ſoon found, that the oyſter and cockle-ſhell lime-water poſſeſſed a much greater power of diſſolving the calculus, than that of the ſtone-lime.

He therefore propoſes the drinking of ſhell-lime-water to the quantity of four pints, every day, for adults; and for children leſs in proportion; and he concludes with inſtances of the happy effects of this method. However, as ſtones of great hardneſs can never be diſſolved by any medicine whatſoever, Dr. Mead recommends, in theſe caſes, a new method of cutting for the ſtone. See LITHOTOMY.

Dr. Hartley has publiſhed, in the London Gazette, the following receipt for making a *lithontriptic* electary. Take five pounds of Alicant ſoap, ſtravd, and one pound of oyſter-ſhell-lime: put them into a tin veſſel, and pour upon them five quarts of water; make the water boil, till the ſoap be perfectly diſſolved in it, and then ſtrain all into a glazed earthen veſſel. Expoſe this maſs to the air, ſtirring it every day till it becomes both mild to the taſte, and of a proper conſiſtence to be formed into pills, or long pellets, without ſticking to the fingers. This may be expected to happen in two or three months. If it becomes ſufficiently mild before it has acquired a due conſiſtence, it may be brought to this, by being heated over the fire, in a tin veſſel: if it acquires a too hard conſiſtence, before it is ſufficiently mild, it muſt be ſoftened with water. This is what the Doctor calls the *lithontriptic* maſs or electary; which he orders to be made in a tin veſſel, becauſe a braſs or copper one would make it emetic.

He gives another more expeditious way of making it, which is this: pour two gallons of water upon a pound of oyſter-ſhell-lime, ſtir it two or three times, and when it has fallen to the bottom, pour off the clear part of the water. Repeat this fifteen or twenty times, or till the clear water, which is poured off, be almoſt taſteleſs; leaving about five pints of water upon the lime, after the laſt ablution. Then pour this mixture of water and ſlaked lime upon five pounds of Alicant ſoap, ſtravd, and proceed as directed in the firſt receipt. The maſs, prepared in this manner, will be fit for uſe in a few days, or even immediately; but then the Doctor prefers the foregoing receipt, where time can be allowed for it.

If the maſs of ſoap, and oyſter-ſhell-lime, diſſolved in either of the above mentioned ways, be made of the conſiſtence of an electary, it is then called the *lithontriptic* electary; which for cure is more convenient than the maſs, for thoſe who deſire to take the medicine diſſolved in a liquid vehicle, as milk, water ſweetened with honey or ſugar, water flavoured with brandy or rum, and ſmall beer.

Where a perſon is ſuppoſed to have a large ſtone in the kidneys or bladder, he ought to take every day as much of the maſs or electary, as contains two ounces of the ſoap, unleſs his pain and provocation to make water be violent; in which caſe it will be proper to begin with about half this quantity, and to increaſe it as he can bear. The medicine ought alſo in this caſe to be diluted in an extraordinary degree.

By this medicine, the Doctor thinks the generation of gravel and gravel-ſtones, may be eaſily prevented. See STONE.

It is likewiſe recommended in diſorders of the ſtomach and bowels, ariſing from, or attended with acidities there; and in gouty habits. The patient may, in many of theſe caſes, begin with ſuch a quantity every day as contains an ounce of ſoap, and afterwards increaſe or leſſen this quantity, as he finds occaſion.

LITHOPÆDION, a word uſed by ſome medical writers, to expreſs a preſent calculous concretion in the bladder.

The ſtone, in this caſe, is ſuppoſed to be more eaſily worked upon by medicines, than when of longer ſtanding; but the cruſtated ſtructure of theſe ſtones, when examined, plainly ſhews that they arrive at their bigneſs only by ſlow degrees, and therefore, that there is properly no ſuch thing as a recent calculous concretion capable of giving pain.

LITHOPHAGI, of λίθος, *ſtone*, and φαγεῖν, *to eat*, a name given to thoſe who are capable of eating and digeſting ſtones; inſtances of which are given by Boyle, Exp. Phil. p. ii. eſſ. iii. p. 80. Bulwer, Artificial Changeling, p. 307. and Paulian, Dict. Phyſique, art. *Digeſtion*.

LITHOPHYTA, in the Linnæan ſyſtem of *Natural Hiſtory*, belong to the genus of CORALLINA, in the claſs of zoophytes. Modern diſcoveries ſufficiently evince, that they are the habitations of animals, as well as the CORAL, and that the animals in this particular ſubſtance occaſion the vertical pain. See KERATOPHYTA.

One of the moſt remarkable ſpecies of the ſmall *lithophyta* we have any where an account of, is that deſcribed by Mr. Ellis in the Philoſophical Tranſactions, N° 486. p. 1430.

LITHOPHYTON, *τροφὸς*, a name given by Mr. Marchant to a ſpecies of plant, approaching to the muſhroom-kind, reſembling that fungous production, compared by ſome authors to the cluſters of the Æthiopian pepper.

Mr. Marchant's curious obſervations on this little regarded ſubject give many valuable hints towards the explaining the vegetation of great numbers of the other plants, whoſe fructification is leſs obvious to the eyes, and may lead to a knowledge of many of the fructifications of ſea-plants; which all our enquiries, on other foundations, have as yet left us unacquainted with.

This gentleman having cut down a maple in his garden, found after ſome months a number of little tubercles, of a fungous ſubſtance on the ſtump; they ſomewhat approached to the figure of an olive, with its ſtalk, and were then of a brown colour.

The outside of these tubercles was porous, and they appeared somewhat spongy through rigid, and on squeezing a little there issued out of the pores a small quantity of an aqueous humidity; the inside, when it was cut open, appeared composed of fine and closely compacted fibres. These plants, as they may properly be called, stood the whole winter, and in the following spring were found to be grown to their full size, which was about an inch and half long, and half an inch thick; they stood in clusters of near twenty together, and resembled a set of irregular and ill-proportioned fingers, and when pressed were found to be much harder than while young. Mem. Acad. Par. 1711.

The pores on their surface, which still continued visible, and were very different from any known plant of the mushroom-kind, gave the observer hopes of a discovery of something new in the fructification, and the stump of the tree being now perfectly dry, and unable to furnish any more nourishment to them, he cut them all off, with part of the stump, and carried them to his closet for observation.

Each plant was nearly circular in figure, and terminated in a roundish or pointed end, and had at several distances two or three circular lines, by means of which it resembled a toe or finger with its joints. The outer skin was now become wrinkled, and the pores were all surrounded with a sort of cutaceous rim, and within them there often appeared a number of fine slender filaments, having the appearance of stamina. On cutting the plants vertically, these pores were all found to correspond with certain round cavities within the plant, which were lined with a black matter. These cavities were formed in a white fibrous matter; all the fibres of which took their origin at the centre, and tended to the circumference, and of these was the whole inner substance of the plant composed.

Some months after this, on cutting more of these plants, the round cavities, in some of them, were found filled with a black matter, in form of a powder, composed of small granules, and looked as if filled up with very fine gunpowder. The help of a microscope shewed this matter to be composed of small black particles, resembling the seeds of the vanilla pods, only vastly less, and not so flaming. On the whole, Mr. Marchant, notwithstanding the external resemblance of this plant to some of the mushrooms, thinks, that when closely examined, it approaches more to the nature of the marine *lithophytons*.

It grows, as he observes, on hard bodies, without any appearance of roots in the manner of those sea-plants. Its bark, or outer covering, seems a sort of cutaneous or tuberous substance, much more resembling the bark of the sea-*lithophytons* than that of any land-plants: and its pores surrounded with cutaceous rims, and answering to certain cavities containing seeds within the body of the plant, bring it to a near resemblance with the sea-*lithophytons*, though they do not at all resemble any known land-plant.

LITHOPHOSPHORUS *Sublimis*, in *Natural History*, a name given by some authors to a species of spar, which, when it has been heated over the fire, retains a property of giving light in the dark. This is a quality that seems more or less in degree to be inherent in several sorts of spars. The Bononian stone is a fossil of this kind; and several of the green spars of the German mines have been found to possess this quality in some degree.

The *lithophosphorus* here meant has the appearance of a common purple spar. There is another kind, of an opake white colour, so common about the edge of the Hartzforest, that it is used as a flux for some of the coppery ores, readily burning into lime, and then acting as an alkali, and absorbing their sulphurs; this kind, when moderately heated, shews an elegant light on being put into a dark room, but when it is heated too much it bursts to pieces.

LITHOPTERIS, *flone-fern*, in *Natural History*, a name given by Mr. Lhwyd to some of the *fossile* PLANTS of the fern kind.

LITHOSPERMUM, in *Botany* See GROMWELL.

LITHOSTROTA, among the *Ancients*, pavements made up of small pieces of cut marble of different kinds and colours. See TESSELATED.

LITHOSTROTION, in *Natural History*, the name of a species of fossile coral, composed of a great number of long and slender columns, sometimes round, sometimes angular, joined nicely to one another, and of a starry or radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens. See *Tab. of Fossils, Class* 7.

LITHOTOMY, formed of λιθος, *stone*, and τεμνω, *I cut*, in *Surgery*, an operation performed upon a human body, in order to extract the stone out of the bladder.

It appears, that cutting was in use for the stone even in the time of Hippocrates, though we are perfectly in the dark as to the manner in which they performed it: it was, however, wholly disused in the after ages; insomuch, that in the beginning of the fifteenth century, there was no body durst practise it. The faculty of medicine at Paris were obliged to petition the parliament, to obtain leave to make a trial on a criminal condemned to death, who had the stone in the bladder: the operation succeeding, the practice became popular.

When a STONE is suspected to be lodged in the bladder, besides the common symptoms of this case, it is useful for a surgeon to make a farther examination, by introducing a catheter, or sound, into the bladder, by which it is possible to feel the stone. In order to this, *Mr.* Sharp directs the following method: the patient being laid on a horizontal table, with his thighs elevated, and a little extended, puts the instrument, with the concave part towards you, until it meets with some resistance in *perinæo*, a little above the anus; then turning it without much force, push it gently on into the bladder, and if it meets with an obstruction at the neck, raise its extremity upwards, by inclining the handle of it towards you; and if it does not then slip in, withdraw it a quarter of an inch, and introduce your fore-finger into the rectum, lift it up, and it will seldom fail to enter. There is some art in turning the sound, in the proper place of the urethra, which surgeons not well versed in this operation cannot so well execute; therefore they may pass the instrument, with the concave side always towards the abdomen of the patient. If the stone is large, the operator, by introducing the sound, may perceive it strike against it, though he cannot thus certainly determine whether it be large or small. Sometimes the operator cannot discover a stone by examination, though there be one; for instances occur in which it is lodged in a fac. Before a patient is examined, he may use a little exercise, such as riding or jumping, by which means the stone may fall down to the neck of the bladder, and be more readily discovered. It is observed, that after the operation, children relapse more frequently than adults; and that adults run greater hazards in the operation than children do.

There are four principal ways of performing the operation; the *apparatus minor*, *apparatus major*, *apparatus altus*, and the *lateral* operation.

The first is by cutting through the perinæum near the suture, on the left side, after the stone, by the fingers of the operator, has been brought to that part. This is called *cutting upon the gripe*; but it is almost disused, because it subjects the patient to great hazards and inconveniencies.

This method was prescribed and practised by Celsus, and by Guido Cauliaco, and hence sometimes denominated the Celsian and the Guidonian method. Heister observes, that this method is practicable in boys under fourteen years of age, because the stone in them may be brought to the perinæum. He says, that he always performed it on children; and that it may be practised on adults, when the stone causes a suppression of urine, by its adhering to the neck of the bladder, but otherwise it is dangerous.

In the *great apparatus*, which is that ordinarily practised, after the patient is conveniently placed and bound, the operator introduces a proper instrument through the urinary passage into the bladder, in order to search for the stone; which being found, that instrument is withdrawn, and another grooved one is introduced the same way; which, bulging in the perinæum, serves to direct the knife to the neck of the bladder: after the incision, a third instrument is thrust into the aperture, till it join the former that was last introduced through the urinary passage, at which time that is withdrawn, whilst this remains to guide the forceps directly into the bladder, to bring away the stone. This way is called *cutting upon the staff*. It was invented by Franciscus De Romanis, a celebrated Italian physician of Cremona, and afterwards improved and published by his pupil Marianus Sanctus, and denominated Marianus's method; and from the large number of instruments used in it, *apparatus major*. But since other methods have been introduced, it has been called the vulgar or old method.

The third method, called also the *high operation*, because it is performed above the ossa pubis in the superior and anterior part of the bladder, and the *sectio hypogastrica*, because the place of the section is in the middle of the hypogastrium, first practised by Pet. Franco, has been since described, and strenuously pleaded for by a chirurgical writer, Rosset; but it soon fell into oblivion; from which it was only recalled about the year 1719, by Mr. Douglas, a surgeon of London, who collecting what scattered hints he could find relating to it, and improving them

them with his own observations, paved the way for its being brought into regular use, which before it never had been. He was soon followed by Mr. Cheselden, and some others. Of thirty-one patients cut by them in this manner, in a few years, twenty-five recovered. It is true, Mr. Cheselden afterwards quitted this method for the lateral operation. Of late years, the French have begun to adopt the high operation; and M. Morand, a surgeon of Paris, has written a book on the subject, chiefly taken from the English writers.

He argues, that the methods of Celsus, Frere Jacques, Raw, and Cheselden, are in the main the same. See Mem. de l'Acad. des Sciences, 1731.

Mr. Cheselden's method is described in his Anatomy, chap. xi. of the fifth edit.

The manner of proceeding herein, is this: after the bladder is inflated with a sufficient quantity of warm water, and the patient conveniently placed, the operator slowly makes an incision above the os pubis, along the linea alba, till he gets sight of the bladder, into which he directly plunges his knife, and afterwards draws out the stone.

The advantages attending this method, are, that it is performed in a very short time; that the wound easily heals; that the dilaceration of parts frequent in the other ways is prevented; and that there is no danger of the incontinencia urinæ. On the other hand, it is thought to be chiefly practicable upon young persons, and such as are lean; the wound in old and fat persons being apt to mortify: moreover, if the operator be not very cautious, he may easily let out the intestines. But Dr. Mead assures us, that now not only children and youths, but also persons advanced in years, may submit to this operation, without great danger; and in case the stone prove too big to be extricated without tearing the neck of the bladder, it is now no longer necessary to split the stone, before the extraction; the invention of which is ascribed to Ammonius, a Greek physician, who from thence was surnamed *lithotomus, the lithotomist*.

Mr. Houlton has collected a great many instances of stones lodged in ures formed in the bladder, from which it was impossible to extract them, without tearing the bladder, or cutting on one side of the os, which M. Garengeot did once with success. In some of the cases which he mentions, the vessels of the bladder were in appearance grown into the stone, and the extraction of the stone was attended with a mortal hemorrhage. See Mem. de l'Acad. de Chirurg. tom. i.

The distension of the bladder with a liquor in performing the high operation for the *stone*, is attended with difficulties, especially in women. Dr. Kulm has therefore contrived an elevatory catheter for that sex. The bending of the instrument is fitted to the turn of the os pubis, and its great curve, instead of being only furrowed, is pierced quite through. He introduces this with its convexity to one side, then gently raises it to the hypogastrium, and cuts securely upon it. See Nov. Act. Erudit. Lipsi Mart. 1732.

To these may be added the *lateral operation*, invented by Frere Jaques, a religious of the third order of St. Francis, towards the close of the last century, and practised by him with great reputation in the Franche Compté. But this reputation it lost again at Paris; which, however, did not hinder Mr. Raw, anatomy-professor at Leyden, from undertaking to rectify what was amiss in it: in which he succeeded, insomuch that the method is now known by his name, which has taken place of that of the first inventor. See Hist. Acad. Roy. Scien. ann. 1699. p. 34; item, an. 1728. p. 31.

Various improvements have been made in this method, and it is yet continued in practice. Mr. Sharp directs it to be performed in the following manner, from Mr. Cheselden, who adopted and improved it: the patient being laid on a table, with his hands and feet tied, and the staff passed, as in the old way, let an assistant hold it a little slanting on one side, so that the direction of it run exactly through the middle of the left erector penis, and accelerator urinæ muscles; then make an incision through the skin and fat very large, beginning in one side of the scam in perinæo, a little above the place wounded in the old way, and terminating a little below the anus, between it and the tuberosity of the ischium. This wound must be carried on deeper between the muscles, till the prostate can be felt, when searching for the staff, and having it properly, if it hath slipped, turn the edge of the knife upwards, and cut the whole length of that gland from within outwards, at the same time pressing down the rectum with a finger or two of the left hand, by which precautions the gut will escape being wounded; after this introduce the forceps to take out the stone. After the operation is finished, if there be an hæmorrhage from the prostate gland, a silver canula, three or four inches long, covered with fine rag, may be introduced into the bladder, and left there two or three days, for it rarely fails to check it: the patient may also take an opiate. If the wound does not bleed, a little dry lint, or a pledget of digestive may be laid in it. If a pain be felt near the bladder, soon after the dressings are finished, a bladder of warm water may be applied over it; and if it increase, as there will be much danger from it, bleeding and clysters will be necessary.

Among Cheselden's emendations, Douglas enumerates these: if he finds the patient's pulse low after the operation, he applies blisters to the arms, which effectually raise his spirits: if the wound becomes callous, he lays on a piece of blister-plaster to erode it, by which new flesh pullulates, and the wound unites: if the wound be putrid, he mixes a little verdegris with some digestive ointment.

Women are rarely afflicted with a stone in the bladder; but when they are, it may generally be extracted through the urethra, which may be gradually dilated to an incredible size. Stones have been extracted through dilated urethræ, which weighed more than five ounces.

Mr. Gooch, in his Cases, &c. vol. ii. p. 183, &c. gives an instance of extracting a stone four ounces in weight, through an incision which he made from the vagina into the bladder. This procedure was attended with very little trouble, either to himself or the patient: the ulcer soon healed by the use of soft balsamic injections, and no inconvenience was observed after the parts were healed. Sharp's Operations of Surgery, Heister's Surgery, part ii. sect. 5. See NEPHROTOMY. For a view of the instruments used in *Lithotomy*, see *Tab. Surgery*.

LITHOXOS. See COLAPTICE.

LITHOXYLUM, in *Botany*, a term used by Linnæus to express a heterogeneous substance on fern-plants, or marine productions, which has incrustations in imperfect points. See KERATOPHYTON.

LITHOZUGIA, in *Natural History*, the name of a genus of fossils, of the class of the SERAPIA, composed of a crystalline matter a little debased, and containing within them various extraneous bodies, as pebbles, &c.

Dr. Woodward has ranked this genus among the pebbles, because of the pebbles they contain; which is by no means a sufficient reason for confounding two such different fossils; the *lithozugia* approaching to the nature of flint.

Mercatus and other naturalists have called the *lithozugia*, *scalati lapides*; and among English lapidaries they are known by the name of *pudding-stones*. See OCULATUS *lapis*.

Of this genus we have three species.

Besides these, there are other *lithozugia* of a coarser texture, approaching to the nature of quarry stone; of these we have four species. Hill's Hist. Foss. p. 562, 562.

LITHUS, a name given by some authors to the magnet.

LITMUS, or LACMUS, in the *Arts*, is a blue pigment, formed from ARCHIL. It is brought from Holland at a cheap rate; but may be prepared by adding quick-lime, and putrified urine, or spirit of urine distilled from lime, to the archil previously bruised by grinding. The mixture, having cooled, and the fluid suffered to evaporate, becomes a mass of the consistence of a paste, which is laid on boards to dry, in square lumps. It is only used in miniature paintings, and cannot be well depended on, because the least approach of acid changes it instantly from blue to red. The best *litmus* is very apt to change and fly.

LITOTES, Λιτότης, in *Rhetoric*. See LITOTES.

LITTER, *lectica*, a kind of vehicle borne upon staffs; anciently esteemed the most easy and genteel way of carriage.

Du-Cange derives the word from the barbarous Latin *lecterium, straw or bedding for beasts*. Others will rather have it come from *lectus, bed*, there being ordinarily a quilt and a pillow to a *litter*; in the same manner as to a bed.

Pliny calls the *litter* the traveller's chamber; it was much in use among the Romans, among whom it was borne by slaves kept for that purpose; as it still continues to be in the East, where it is called a PALANQUIN.

The Roman *lectica*, made to be borne by four men, was called *tetraphorum*; that borne by six, *hexaphorum*; and that borne by eight, *octapherum*.

The invention of *litters*, according to Cicero, was owing to the kings of Bithynia: in the time of Tiberius they were become very frequent at Rome, as appears from Seneca; and even slaves themselves were borne in them, though never by more than two persons, whereas men of quality had six or eight.

LITTLE *bairam*. See BAIRAM.

LITTLE *capitan*. See CAPITAN.

LITTLE *mass*. See MASS.

LITTORAL *fossils*, among writers of *Natural History*, are such

such sea-shells as are always found near the shores, and never far off in the deep.

Those which are found in the bottom of the sea, remote from the shore, are called *pelagium*.

LITUITES, a name given to the stones formed in the lituus-shell.

LITURGY, denotes all the ceremonies in general belonging to divine service.

The word comes from the Greek λειτουργια, *service, public ministry*; formed of λαος *people*, and εργον, *work*.

In a more restrained signification, *liturgy* is used among the Romanists to signify the mass; and among us the common-prayer.

All who have written on *liturgies* agree, that in the primitive days, divine service was exceedingly simple, only clogged with a very few ceremonies, and consisting of but a small number of prayers; but, by degrees, they increased the number of external ceremonies, and added new prayers, to make the office look more awful and venerable to the people. At length things were carried to such a pitch, that a regulation became necessary; and it was found proper to put the service, and the manner of performing it, into writing, and this was what they called a *liturgy*.

Liturgies have been different at different times, and in different countries. We have the *liturgy* of St Chrysostom, that of St. Peter, of St. James, the *liturgy* of St. Basil, the Armenian *liturgy*, the *liturgy* of the Maronites, of the Cophtæ, the Roman *liturgy*, the Gallican *liturgy*, the English *liturgy*, the Ambrosian *liturgy*, the Spanish and African *liturgies*, &c.

In the more early ages of the church, every bishop had a power to form a *liturgy* for his own diocese; and if he kept to the analogy of faith and doctrine, all circumstances were left to his own discretion. Afterwards the practice was for the whole province to follow the metropolitan church, which also became the general rule of the church: and this Lindwood acknowledges to be the common law of the church; intimating, that the use of several services in the same province, which was the case in England, was not to be warranted but by long custom. The *liturgy* of the church of England was composed in the year 1547, and established in the 2d year of King Edward VI. stat. 2. and 3 Ed. VI. cap. 1.

In the fifth year of this king it was reviewed; because some things were contained in that *liturgy*, which shewed a compliance with the superstition of those times, and some exceptions were taken against it by some learned men at home, and by Calvin abroad. Some alterations were made in it, which consisted in adding the general confession and absolution, and the communion to begin with the ten commandments. The use of oil in confirmation, and extreme unction were left out, and also prayers for souls departed, and what tended to a belief of Christ's real presence in the eucharist. This *liturgy* so reformed, was established by the act of 5 and 6 Ed. VI cap. 1. However, it was abolished by Queen Mary, who enacted that the service should stand as it was most commonly used in the last year of the reign of King Henry VIII. The *liturgy* of 5 and 6 Ed. VI. was re-established with some few alterations and additions, by 1 Eliz. cap. 2. Some farther alterations were introduced, in consequence of the review of the Common Prayer Book, by order of King James, in the first year of his reign; particularly in the office of private baptism, in several rubricks and other passages, with the addition of five or six new prayers and thanksgivings, and all that part of the catechism which contains the doctrine of the sacraments. The book of Common Prayer, so altered, remained in force from the first year of King James, to the fourteenth of Charles II. But the last review of the *liturgy*, was in the year 1661, and the last act of uniformity enjoining the observance of it, is 13 and 14 Car. II. cap. 4. See COMMON *Prayer*. Many applications have been since made for a review, but hitherto without success.

LITUS, in *Medicine*, the same as LINIMENT.

LITUUS, among *Antiquaries*, the staff used by the augurs, made in form of a crozier.

We frequently see it on medals, along with other pontifical instruments. Aulus Gellius says, it was bigger in the place where it was crooked, than elsewhere.

LITUUS, in *Natural History*, a name given to a genus of shells of the class of the *polythalamia*, or those which consist of several consentaneous or chambers, parted from one another by shelly diaphragms, and communicating with one another by means of a siphunculus, which runs through the whole length of the shell. To this general character of the class, it is to be added, that the *lituus* is always a conic shell, running in a strait line from the mouth, through a great part of the length, and from the end of this strait part to the extremity, twisting into the shape of a cornu Ammonis, or spiral shell of that kind.

It is thus named from its resembling the instrument called *lituus* among the ancients. The stony matter often found cast in this shell, and resembling all its lineaments, is called by authors *lituites*, as those stones formed in the pecten *pectinites*, and those in the echini marini *echinites*.

LIVE *caves*, in *Mining*, a phrase used by many people, to express such caverns in the earth as have but little communication with the external air, and are found to abound with mineral productions. The workers in the lead-mines on Mendip-hills distinguish the numerous caverns in those places into the *live* or *quick caves*, and the *dead caves*; the latter are such as admit the air into them two or three ways, and are barren of any thing valuable; the others have only one passage, and that but narrow and winding, and generally lie at great depths. These abound in numerous elegant productions. They almost always contain ore in some form or other, and usually abound in elegant spars. Mr. Beaumont mentions one of these in the Philosophical Transactions, which lay at thirty-five fathom perpendicular depth, to which there was found a fine liver-coloured earth, of the nature of bole armenic, which in many places shoot up in a wonderful manner into a sort of spires of the height of three or four inches, formed with *ridges* and furrows, and usually covered with spar at the top; sometimes all the way down, to the bed of earth. Phil. Trans. N° 229.

LIVE *over*, in *Botany*. See OVERSE.

LIVE *to ground*. See VIOLET.

LIVER, in *Anatomy*, a large, glandulous viscus, of a dark red colour, a little inclined to yellow, situated immediately under the diaphragm, partly in the right hypochondrium, which it almost fills, and partly in the epigastrium; stretching itself over the right side of the stomach, towards the left hypochondrium, and reaching behind the cartilago ensiformis, growing gradually thinner and narrower; it serves to purify the mass of blood, by making a secretion of the bilious humour it contains. *See Tab. Anat. (Splanchn.) fig. 1. lit. a & fig. 3. lit. b. (Angiol.) fig. 4. lit. a a a, &c. fig. 5.*

Plato, and others of the ancients, fix the principle of love in the *liver*; whence the Latin proverb, *Cogit amare jecur*: and in this sense Horace frequently uses the word, as when he says, *Si torrere jecur quæris idoneum*. The Greeks, from its concave figure, called it ἧπαρ, *vaulted, suspended*; the Latins call it *jecur*, q. d. *jacitur cor*, as being near the heart. The French call it *foie*, from *focus*, *fover*, or fire-place; agreeable to the doctrine of the ancients, who believed the blood to be boiled and prepared in it. Erasistratus, at first, called it *parenchyma*, i. e. *effusion*, or *mass of blood*: and Hippocrates, by way of eminence, frequently calls it the *hypochondrium*.

The upper part of the *liver* is convex, and perfectly smooth: the under is concave, and somewhat more uneven, having four large fissures; one, through which the umbilical ligament passes; a second on the left side, receiving the pylorus, and the beginning of the duodenum; a third on the right side, near the margin, in which the gall-bladder is lodged; and the last in the upper part, affording the passage to the vena cava.

Its figure is somewhat approaching to round, with thin edges, not altogether even, but notched in some places. Its magnitude is various in different subjects, according to the proportion of the body; though in a fœtus, or very young animal, it is always larger, in proportion, than in adults. In dogs, and other animals of the quadruped kind, it is divided into several distinct lobes; but in men it is generally continued; having one small protuberance, which some account a little lobe. It is sometimes, however, observed, in men, to have been divided into two or three lobes.

The two lateral parts are usually called the lobes, and distinguished above by a membranous ligament, and below by a considerable fissure lying in the same direction with the superior ligament. The right or great lobe of the *liver*, which lies in the right hypochondrium, rests on the right kidney, and covers a portion of the arch of the colon and pylorus; about two thirds parts of the small or left lobe, lie in the middle of the epigastrium, and the remaining thick part advances over the stomach, towards the left hypochondrium. This small lobe is situated almost horizontally; the great lobe is very much inclined, and its thick extremity runs down almost in a perpendicular direction to the right kidney, on which it lies.

The *liver* is connected to several parts, but especially to the diaphragm, to which it is fastened by a broad, thin, but strong semicircular ligament, called the *suspensory ligament*, derived from the common capsula of the porta and gall-bladder. The continuity of this ligament, being interrupted by the perforation of the vena cava, has given occasion to some anatomists to divide it into two. It is likewise,

likewise, by another strong ligament, which has its original from the external coat of the *liver*, or, which amounts to the same, from the peritonæum, tied to the cartilago xiphoides; and by a third, which is formed out of the umbilical vessels, which, in adults, dry up, and become a ligament, it is connected to the tendons of the abdominal muscles in the linea alba, at the navel. These several ligaments serve to keep it in its due situation: besides which, it has some other connexions by the blood-vessels.

When the stomach is empty, or when we fast longer than ordinary, it is commonly said that the stomach pinches us: as the *liver* is not then sustained by the stomach and intestines, it descends by its own weight, and chiefly by means of the suspensory ligament, pulls the diaphragm along with it: it is in that place, therefore, that we have this uneasy sensation, and not at the superior orifice of the stomach, as is commonly believed.

The *liver* has a motion, though not proper to itself, but depending on that of the diaphragm; to which being very firmly connected, it must needs obey its motion: and in expiration be drawn up, and in inspiration be let down again. It is covered with a thin smooth membrane, derived from the peritonæum, which may be separated from the substance of the *liver*, though not without some danger of laceration. The substance of the *liver* is vascular and glandulous; which latter part is very soft and friable, and pretty easily scraped off from the vessels, to which the glands every way adhere, as it were in bunches; which has made the anatomists call the considerable ones, *the internal lobes of the liver*.

The glands adhering thus to the vessels, and constituting those lobes, are wrapped up together in proper membranes; whence this appearance of distinct lobes. Every one of these glands, according to Malpighi, is compofed of six unequal sides, or faces. They are all clothed with their proper membranes, and have each an excretory duct; several of which, joining together, form little trunks, which run all along with the branches of the porta; and these again, uniting, form longer trunks, which are always found full of bile, and constitute the porus biliarius; which, being distributed all over the *liver*, receives, in the foregoing manner, the bile; which is separated by these glands; and, terminating in the meatus hepaticus, and in the ductus communis, at length discharges the bile into the duodenum.

Besides this discharge by the porus biliarius, which is supposed to be the great one, the *liver* also delivers part of its bile into the gall-bladder, by a duct, called the *cysti-hepatic duct*, first discovered by Dr. Glisson; by means whereof, there is an immediate communication between the porus biliarius and the gall-bladder; a particular description of which laft part see under the words GALL, CYST-HEPATIC, &c.

Each lobule of the *liver* consists of an external friable, yellowish-red, cortical substance, and of an internal soft, pulpous, medullary part. The medullary substance is the pulpy extremities of the biliary ducts, proceeding from the cortical part. See Mr. Ferrein in Hist. de l'Acad. des Scienc. 1733.

The blood in the hepatic artery has bile secreted from it, and its remaining blood is conveyed by veins into the vena portarum, where a second secretion is made from it. Besides, the secretion of bile made from the hepatic artery and vena portarum, Mr. Ferrein has seen biliary ducts coming from the left ligament of the *liver*, the diaphragm, coats of the gall-bladder, and part of the vena cava; all which are visible upon injecting coloured liquors into the trunks of the hepatic ducts. The bile is equally bitter and strong in the smallest biliary canals as in the larger trunks; the thick yellow bile, sometimes found in the trunks, being the cystic bile, remounting from the common into the hepatic duct, on which account the hepatic is often larger than the common duct. The lymphatic vessels may be traced to the extreme branches of the vena portarum, and to the biliary ducts, by injecting liquors into the larger trunks of the external lymphatics. Ferrein, ubi supra.

Besides these gall-vessels, which are peculiar to the *liver*, it abounds with blood-vessels, especially veins; whereof the porta and cava are disseminated through the whole substance of it. And here it is particularly remarkable of the porta, that after the manner of arteries, it shoots itself from a trunk into branches; and being at last lost in capillaries, delivers the blood into the cava, by which it is immediately reconveyed to the heart.

The porta is formed out of the concurrence of divers veins, which, meeting together, make one of the most considerable venous trunks of the body, as to its bulk; though, contrary to the course of other veins, it runs not far in a trunk, but is soon distributed again by ramifications into the *liver*.

The blood conveyed into the *liver* by the porta, after the manner of the arteries, is received again, after having been purged of its bile in the glands of the *liver*, into innumerable veins, which empty themselves into the cava; and are vulgarly, though improperly, called *branches* of the cava; but they ought to be esteemed the proper blood-vessels of the *liver*, as the emulgents are of the kidneys; and which, as all the rest do, excep t the pulmonary vein, empty themselves into the cava; the common channel by which the blood returns to the heart.

The arteries, which are called the *hepatic*, come from the right branch of the coeliac. Dr. Glisson thinks the porta does so much the office of an artery, that no more arteries are necessary than those which furnish nourishment to the membranes and capsulæ; but Dr. Drake judges they serve for the nourishment of the whole part. These arteries are much bigger in men, than in other animals. Mr. Cowper had several preparations, wherein the stem of each hepatic artery was as large as a goose-quill, and the branches in the *liver* everywhere equal in magnitude to those of the porus biliarius, which they accompany. Dr. Drake conjectures, that in this viscus in a human body, a larger stream, and more direct impetus, of arterious blood is required to drive on the venous, because of the erect posture, than in animals of a horizontal position of body. For which reason horses, &c. though of much larger size, and having much bigger *livers*, have these arteries much smaller than men; and not only so, but curled like the tendrils of a vine, to break the impetus, which, in that posture, is not so necessary as in the erect. The *liver* has its nerves from the hepatic plexus, formed on the right hypochondrium by the branches of the intercostal, which, wrapping themselves about the arteries, make a sort of net-work; and after spreading themselves on the membrane and surface, disappear. The lymphe-ducts are numerous, though not easily discernible in human subjects, for want of live dissections; but in other animals, that may be dissected alive, they become very conspicuous, by applying a ligature to the porta, and the biliary duct.

LIVER, *for the use of the, in the secretion of bile*, see BILE.

Those things which increase or lessen the proportion of the weight of the heart to the weight of the body, do at the same time lessen or increase the proportion of the weight of the *liver* to the weight of the HEART. And consequently, when an animal grows fat from much food, much sleep, and little exercise, its heart lessens, and its *liver* increases; and, on the contrary, when an animal grows lean from little food, little sleep, and much exercise, its heart increases and its *liver* lessens. When the weight of the heart is too little for the weight of the body, the *liver* enlarges beyond its just magnitude, and presses too much on the contiguous parts, particularly on the stomach, intestines, and diaphragm, and by the pressure lessens the capacities of the stomach, intestines, and thorax; whence the appetite grows less, the peristaltic motion less, and respiration more difficult and uneasy.

The weight of the *liver* in proportion to the quantity of blood, is less at a medium in wild beasts than in tame, and in round fish than in flat fish.

In most chronical diseases the *liver* is larger than in health, as has been found by dissections. And it seems probable, that the weight of the heart, and quantity of blood, in those distempers, are both less than in health: most chronical diseases arising from too much food and too little exercise, lessen the weight of the heart and quantity of blood, but increase the *liver*. Hence, when this part is grown too large by intemperance and inactivity, it may be lessened and brought to a healthful magnitude by temperance and exercise. It may indeed also be emptied by art, but nothing can prevent its filling again, and consequently secure good and constant health, but an exact diet and exercise. Thus purging and vomiting may lessen the *liver*, but cannot prevent its increasing again, so long as persons live too full and use too little exercise. Dr. Robinson's Diss. on the Food, &c. of Hum. Bod. p. 111, &c.

The *liver* in fishes is generally very large in proportion to the rest of the body, and is generally placed in the left side of the abdomen; but this is not the case in all. In figure and proportion it differs greatly in the different kinds; it is in some simple and undivided, as in the pleuronectes, petromyzon, salmons, &c. In some it is divided into two lobes, as in pearch, and most of the cartilaginous kinds. As also in the torpedo, the squali, the lamiæ, the periophus, the psalthachs of authors, the cluper, the eels, the stromateus of Rondeletius, the dolphins, and all some of the hyeri. In some it is divided into three lobes, as in the cyprini, some of the gadi, the scorpænæ, the rays, the squatinæ, the tunny, the gasterosteus, and the labri, or Solen doree. Artedi, Ichthyol.

In regard to proportion, it is in some fish much shorter than the abdomen; as in pearch, clupea, osmari, coregones, salmons, esoces, and the greater part of fishes. In some it is nearly of the same length with the abdomen, as in the gasterosteus, &c.

The gall-bladder, which is an appendage to the *liver*, is never wanting in any kind of fish, but it is very differently situated in the different kinds. In the cartilaginous fishes, it is immersed in the substance of the *liver*; in other fish, it sometimes adheres closely to the lower part of it, as in the esoces, cyprini, pearch, and the greater part of fishes. In others it is hung to the *liver* by a long neck, as in the murænæ, conger, and ammodytes.

Liver, *abscess in the*. Abscesses in the *liver* have been usually accounted mortal, and wholly beyond the reach of remedy; we have, however, in the History of the Academy of Paris, an account of a very remarkable one, perfectly cured by Mr. Souiller, a surgeon of Montpelier, in the following manner. The patient was a young gentleman of about fourteen, who had contracted a violent fever, by putting his feet while very hot into some cold water. The consequence of this fever was a large tumor in the middle of the epigastric region, which raised the xiphoide cartilage, and pushed it two inches out of its place, and terminated below, two inches under the navel. The common means failing to do any service, the patient was sent to Montpelier, where the beforementioned surgeon opened the tumor; on this the *liver* was found abscessed in its anterior or convex part, and a cavity was found there capable of receiving half a hen's egg, and there issued out of it on a gentle pressure a thick and bloody, sometimes a yellowish bitter and inflammable matter. This last was true bile, and both with this and with the other discharge, there always came away small portions of the substance of the *liver*, and the small extremities of numbers of vessels might be perceived, some sanguineous, some bilious.

The great business for the surgeon, in this case, was the getting the matter out of the abscess, the preventing its remaining in the substance of the *liver*, or being again received into the blood. For this purpose, Mr. Souiller invented a particular canula, made very soft at the end, where it was to be passed into the *liver*, and having there six lateral holes capable of receiving the matter. This canula was of silver, and under its other end there was placed a thin plate of lead, to receive the matter which was discharged through it, which would otherwise have excoriated any part on which it fell. The abscess, which was, by this means, always kept perfectly clean, soon began to heal; the fever went off by degrees, the patient every day grew into a better state, and finally, the wound was cicatrized, and all perfectly cured in a very short time. Hist. Acad. Par. 1736.

One thing observable in the course of the cure, was the refutation of a common opinion, that the bile is neither bitter nor coloured, till it gets into the gall bladder; for, in this case, it was discharged yellow and bitter from the wounded vessels of the *liver*.

Wherever an abscess or imposthume is formed in the *liver*, all methods should be tried to make it break and discharge itself outwardly, as fomentations, poultices, ripening cataplasms, &c. Sometimes the matter of an abscess comes away in the urine, and sometimes it is discharged by stool; but these are efforts of nature, which no means can promote. When the abscess bursts into the cavity of the abdomen at large, death must ensue; nor will the event be more favourable when the abscess is opened by an incision, unless in cases where the *liver* adheres to the peritonæum, so as to form a bag for the matter, and prevent it from falling into the cavity of the abdomen; in which case, opening the abscess by a sufficiently large incision, will probably save the patient's life. Buchan. Dom. Med. p. 335. See Hepatitis.

Liver, *infarctions of the*. See Hepatis *Infarctio*.

Liver, in *Antiquity*, was much used in divination. See Hepatoscopia.

Liver *of antimony*, in *Chemistry*, results from the detonation of antimony with an equal weight of nitre. These two matters reduced into powder are to be mixed together, and put into a large crucible. The mass is then to be kindled, and the detonation to be made. When it has detonated, it is to be kept in fusion and then cooled. When the crucible is broken, at the bottom two distinct matters are found, which may be separated from each other by the stroke of a hammer. The upper matter is a saline scoria, nearly of the same nature as the scoria of the regulus of antimony. This is a true antimonial *liver* of sulphur, mixed with a certain quantity of vitriolated tartar. The lower matter is heavier. It is opake, compact, red and brittle. This is the *liver* of antimony. Its colour and appearance have been supposed similar to those of the *livers* of animals, whence its name. It is principally composed of the metallic part of antimony, half deprived of its sulphur, and dephlogisticated by nitre. This substance is of no use in chemistry, nor in medicine since the kermes mineral and emetic tartar have been introduced. Dict. Chem. See Antimony.

Liver *of arsenic*, is a combination of white arsenic with liquid fixed vegetable alkali, or by the humid way. The operation for making *liver* of arsenic is easy and simple: to strong and concentrated liquid, fixed alkali, previously heated, fine powder of white arsenic must be added, till the alkali is saturated, or has lost its alkaline properties. While the alkali dissolves the arsenic, it acquires a brownish colour, and a singularly disagreeable smell; and the mixture gradually thickens into a gluey consistence. Dict. Chem. See Arsenic.

Liver *of sulphur* is the combination of sulphur with alkaline matters; and this combination may be made either in the dry or humid way. In the dry way, or by fusion, a mixture of equal parts of fixed alkali and sulphur is put into a crucible and quickly fused. The melted mass is then poured on a greased stone, and then the *liver* of sulphur congeals and acquires a brown colour. It is to be required to be kept dry, it must be soon broken to pieces, and put, while it is hot, into a bottle well-corked, because it readily imbibes moisture from the air. In the humid way, which is less common, concentrated liquid fixed alkali, and fine powder of sulphur are to be boiled together, till the alkali has dissolved as much as it can: the liquor is then to be filtrated and evaporated.

Liver of sulphur is an important combination in chemistry, because it is in general a very powerful solvent of metallic matters; all which, excepting zinc, it attacks, particularly in fusion. It seems to dissolve gold more effectually than other metals. It dissolves also vegetable coals, even by the humid way; and the solution is of a green colour. Particular kinds of *livers* of sulphur may be formed by the combination of volatile alkali, of quicklime, or of absorbent earths, all which attack sulphur more or less. Dict. Chem. See Sulphur.

M. Navier has lately discovered, that the *liver* of sulphur, and particularly of *liver* of sulphur of Mars, hath the most salutary effects as an antidote against arsenic, corrosive sublimate, verdigrease and lead. Nav. Contre Poisons de l'Arsenic, &c. 1777.

Liver-*wort*, *hepar*, in *Botany*, the name of a large genus of *cryptogamia flagri*, according to Linnæus, but of mosses according to other writers: the characters of which are these: they have the most perfect fructification of all the mosses, having evident flowers as well as seeds; their flowering heads are of various figures, and have a number of monopetalous flowers in them, divided into a different number of segments; these have several filamentary, and among them have a large quantity of a farina, which when examined by the microscope appears of a globular figure; the seeds are produced in other parts of the plant, and are contained in certain cups, which stand without pedicles on the surface of the leaves; these are sometimes on the same individual plant, with the flowering heads, but sometimes they are on different plants of the same species.

Besides these and the flowering heads, there are also in some species of *lichen*, certain other heads of the shape of a button, standing on pedicles, and containing neither flowers nor seeds; these are always found on such plants as have no male flowers; the pedicles of these, as well as of the male flowers, are usually naked, or without any covering at the base. To this it may be added, that the leaves of the *lichens* are less pellucid, and more like the leaves of the larger plants than those of the other mosses; and that they are of an irregular and indeterminate figure, spreading themselves every way upon the ground, and sending out roots from the underside in various places. Dillen. Hist. Muscor. p. 516.

The *lichens*, being a numerous family of plants, are by Dillenius divided into different orders.

The first order comprehends the pileated *lichens*, or such as have not the starry flowering heads of the more common kinds, of these there are only five known species.

The second order of the *liver-worts* comprehends those which have radiated or stellated heads.

The third order of the *lichens* comprehends those, the flowers and seeds of which are less accurately distinguished than those of the former kinds.

There is scarcely any genus of plants, of which botanical writers have given more various accounts than that which is the subject of this article. Mr. Ray has interspersed the *lichens* among other mosses, under the character of *muscis floribus seu asperis*. Dr. Morison separated them from the herbaceous mosses; and, from the analogy they had with the fungus tribe, formed them into a genus under the name of *muscis fungus*, and enumerated above fifty species of them, dividing them into five orders, according to their different appearances. Tournefort was the first who adapted the generical term *lichen* to them,

in

in consequence of his joining them to the *lichen* of the shops. Dr. Dillenius called them *lichenoides*, appropriating the word *lichen* to the liver-wort of the shops. Micheli, after Tournefort, adopts the term *lichen*, and comprehends all the species under it, except one or two which he calls *lichenoides*. This author describes the liver-wort of the materia medica under the name of *marchantia*. In his Nova Plantarum Genera, they are divided into thirty-eight orders or subdivisions. Dr. Haller retains Micheli's term, and enumerates one hundred and sixty kinds, in his Enumeratio Stirpium Helvetiæ, dividing them into seven different orders. Linnæus, and the followers of his method, who seem to have established their generical character from Micheli's discoveries, retain also his generical title. Micheli enumerates two hundred and ninety-eight species, but Linnæus recounts only ninety-five species belonging to this genus, which he distributes into nine orders, according to their different appearance, little or no regard being had to what are usually called the parts of fructification: they are as follow, 1. *Leproſi tuberculati*. 2. *Leproſi ſcutellati*. 3. *Imbricati*. 4. *Foliacei*. 5. *Coriacei*. 6. *Umbilicati, ſquamulati quaſi ſubrotæ*. 7. *Scyphiferi*. 8. *Fruticuloſi*. 9. *Filamentoſi*. Dillenius, in his Hiſtoria Muſcorum, has divided this Michelian genus into three, under the names of *muſci, coralloides*, and *lichenoides*. Under the firſt he comprehends the hairy tree-moſſes; under *coralloides*, he deſcribes thirty-nine ſpecies, diſtributed into three orders, and the genus of *lichenoides* comprehends one hundred and thirty-five ſpecies, divided into two orders, and ſubdivided into diſtinct ſeries or claſſes. Dr. Hill has diſpoſed them into two genera, *viz. Uſnea*, comprehending the hairy tree-moſſes; *phyſcia*, including the flat-branched tree-moſſes, lung-wort and others; *cladonia*, containing the archel and coralline moſſes; *pyxidium*, the cup-moſſes; and *placodium*, the cruſtaceous moſſes. The plants of this extenſive genus are very different in their form, manner of growing, and general appearance; on which account, thoſe authors, who preſerve them under the ſame name, were conſtrained to arrange them into different orders and ſubdiviſions, for the eaſier diſtinction of the ſpecies. So far as the parts of fructification are diſtinguiſhable in theſe plants, they appear in different forms upon different ſpecies; on ſome, in the form of tubercles; on others, in the form of little concave diſhes, called *ſcutellæ*; on others, of oblong flat ſhields or pelts. All theſe are conceived by Micheli and Linnæus to be receptacles of male flowers. The female flowers and ſeeds are ſuſpected by the ſame authors to be diſperſed in the form of farina or duſt, upon the ſame plants, and in ſome inſtances in ſeparate ones. Dr. Watſon has diſtributed them into ſeveral orders: viz. 1. The *lichens filamentoſi*, conſiſting of mere ſolid filaments, of a ſolid but flexible texture, having the appearance of fructification in the form of ſcutellæ, or flat round bodies growing from the ſides or extremities of theſe filaments, to this order he has reduced the uſnea of Dillenius and Hill, ſeveral of the ſpecies of the fifth order of *lichens* of Micheli, and the *lichenes filamentoſi* of Linnæus: 2. The *lichenes fruticuloſi*, conſiſting of a tough flexible matter, formed into ramifications, in ſome ſpecies almoſt ſimple, in others reſembling ſmall ſhrubs; in ſome of the ſpecies the branches are quite ſolid, in others tubular. This order comprehends the third of Dillenius's genus of *coralloides*, the whole *cladonia* of Hill; the ſecond and ſeveral ſpecies of the third order of Haller's *lichens*; ſeveral ſpecies of the fifth, and the whole ſixth order of Micheli; and the *lichenes fruticuloſi* of Linnæus. The orchel or argol belongs to this order. 3. The *lichenes pyxidati*, conſiſting of a firm tough flexible matter, formed into ſimple tubular ſtalks, whoſe tops are expanded into the form of little cups. This diviſion contains the cup-moſſes of authors; the ſecond order of *coralloides* of Dillenius; great part of the firſt order of *lichens* in Haller; the ſeventh, eighth, ninth, and tenth order of Micheli, and the *lichenes ſphyphiferi* of Linnæus. 4. The *lichenes cruſtacei*, conſiſting of a dry and friable matter, more or leſs thick, formed into flat cruſts, very cloſely adhering to whatever they grow upon. This diviſion contains the firſt order of the *lichenoides* of Dillenius; the fifth, ſixth, and ſeventh orders of Haller's *lichens*, the *lichenes leproſi* and cruſtacei of Linnæus, and ſeveral of the placodium of Hill. 5. The *lichenes ſubcacti ſcutellati*, conſiſting of a more lax flexible matter, formed into a foliaceous appearance, having the parts of fructification in the form of *ſcutellæ*. This diviſion contains, in general, the whole firſt ſeries of the ſecond order of *lichenoides* in Dillenius; the firſt diviſion of the ſecond ſeries, and the latter part of the ſecond diviſion, of the ſame; the *lichenes* imbricati and umbilicati of Linnæus, and many of the *placodium* of Hill. 6. The *lichenes craſſi ramoſi plani*, conſiſting of a firm tough matter, diſpoſed into flat and thin ramifications growing erect, and bearing their *ſcutellæ* upon the edges, ſurfaces, and at the extremities. This diviſion comprehends the flat-branched tree-moſſes of authors; many of the fourth order of Haller's *lichens*; the firſt part of the ſecond diviſion of the two ſeries in Dillenius; and the *phyſcia* of Hill; and 7. The *lichenes peltati*, conſiſting of a tough or coriaceous matter, diſpoſed into a foliaceous appearance; on the edges of which, in general, the parts of fructification are placed, in the form of ſtalkleſs oblong bodies, in theſe moſſes called ſhields or pelts. This diviſion contains the third ſeries of the ſecond order of Dillenius's *lichenoides*; the *lichenes coriacei* of Linnæus, and ſeveral of the *placodium* of Hill. The aſh-coloured ground liver-wort of Ray, ſo famous for the cure of the bite of a mad dog, belongs to this order. See an elaborate article on this ſubject in the Phil. Tranſ. vol. l. art. 91. p. 652.

There are two ſpecies of *liver-wort*, which have been, in a more diſtinguiſhed manner, uſed in medicine: viz. the common broad-leaved *liver-wort*, or *hepatica fontana*, and the aſh-coloured ground *liver-wort*. The firſt ſort grows on the ſides of wells, and in moiſt ſhady places, not only on the ground, but on ſtones, bricks, or wood. The ſecond ſort grows on commons and open heaths, where the graſs is ſhort, in moſt parts of England, eſpecially in declivities and the ſides of pits.

The Engliſh name *liver-wort* expreſſes the good opinion the world has had of it in all diſorders of the liver. It is grown out of uſe with us at preſent, but the German phyſicians preſcribe it, and it is ſaid with ſucceſs in jaundices, and alſo in bedtics. There are authors alſo who recommend it greatly in inflammatory fevers, in cutaneous eruptions, and in a gonorrhœa, but we have not ſo good accounts of the benefit received by it in theſe as in the other. Externally, it is recommended for ſtaunching the blood in freſh wounds; given in powder, in a doſe of about two ſcruples, it is excellent to ſtop the bleeding at the noſe, profluvia of the menſes, or any other hæmorrhages; it acts by incraſſating the blood. There are ſome families in the weſt of England who prepare a medicated drink, which they pretend to be a cure for cancers, in which this plant is the principal ingredient. The ancients recommended it as a remedy againſt laſſitude; they uſed it in baths and ointments. It has an Engliſh name, *cheeſe-rennings*, from its property of coagulating, or curdling freſh milk, and by a dry diſtillation it yields a manifeſt acid. See LAVER-*broad*.

The grey-ground *lichen* is famous for its virtues againſt the bite of a mad dog. It makes the baſis of the *pulvis antilyſſus* of the diſpenſatories.

The *lichen* is a principal ingredient in Dr. Mead's recipe for the bite of a mad dog. See MADNESS.

LIVER-*wort, noble, hepatica*, a ſpecies of the ANEMONE.

LIVERY, properly ſignifies a colour, to which a perſon has ſome particular fancy, and by which he chooſes to diſtinguiſh himſelf, or his retainers, from others.

Liveries are uſually taken from fancy, or continued in families by ſucceſſion. The ancient cavaliers, at their tournaments, diſtinguiſhed themſelves by wearing the *liveries* of their miſtreſſes: thus people of quality make their domeſtics wear their *livery*.

Father Meneſtrier, in his Treatiſe of Caroufals, has given a very ample account of the mixtures of colours in *liveries*. Dion tells us, that Cenomaus was the firſt who invented green and blue colours for the troops which, in the circus, were to repreſent land and ſea-fights.

The Romiſh church has alſo her ſeveral colours and *liveries*; white, for confeſſors and virgins, and in times of rejoicing; black, for the dead; red, for the apoſtles and martyrs; blue or violet, for penitents; and green, in times of hope.

Formerly, great men gave *liveries* to ſeveral, who were not of their family or ſervants, to engage them in their quarrels for that year; but this was prohibited by the ſtatutes 1 Rich. II. 1 Hen. IV. cap. 27. 2 & 7 Hen. IV. 8 Hen. VI. cap. 4. 8 Ed. IV. cap. 2. and no man, of whatever condition, was allowed to give any *livery*, but to his domeſtic officers, and counſel learned in the law. However, moſt of the above ſtatutes are repealed by 3 Car. I. cap. 4.

LIVERY, in *Law*, alſo denotes the delivery of poſſeſſion to thoſe tenants which held of the king in *capite*, or by knights ſervice. See POSSESSION.

LIVERY is alſo uſed for the writ, which lies for an heir to obtain the poſſeſſion or ſeiſin of his lands at the king's hands. By 12 Car. II. cap. 24. all wardſhips, *liveries*, &c. are taken away.

LIVERY *of ſeiſin*, is a delivery of poſſeſſion of land or tenements, or things corporeal, to him who hath right, or probability of right, to them.

Livery of ſeiſin, is a ceremony uſed in the common law,

in conveyance of lands, tenements, &c. where an eſtate in fee-ſimple, fee-tail, or other freehold, paſs; and is a teſtimonial of the willing departing of him who makes the *livery*, from the thing whereof the *livery* is made, as well as of a willing acceptance by the other party, of all that whereof the firſt has diveſted himſelf. *Livery of ſeiſin* is either in *deed* or in *law*.

The uſual manner of *livery of ſeiſin* in *deed* is thus performed. If it be in the open field, where is no houſe nor buildings, and if the eſtate paſs by deed, the feoffor, feoffor, or his attorney, openly reads it, or declares the effect of it; and after that is ſealed, the feoffor takes it in his hand, with a clod of earth, or a twig or bough, which he delivers to the feoffee, in the name of poſſeſſion, or ſeiſin, according to the purport of the deed. If there be a houſe or building on the land, the ceremony is to be done at the door of it, none being then left within; and the ring of the door is delivered to the feoffee, who enters alone, ſhuts the door, and preſently opens it again. If it be a houſe without land or ground, the *livery* is made, and poſſeſſion given, by delivery of the ring of the door and deed only; and where it is without deed, either of lands or tenements, there the party declares by word of mouth, before witneſſes, the eſtate he parts with; and then delivers ſeiſin, or poſſeſſion, as aforeſaid: in which caſe the land paſſes as well as by deed, by virtue of the *livery of ſeiſin*.

If the conveyance or feoffment be of divers lands, ſcattered in one and the ſame county, *livery of ſeiſin* of any parcel in the name of the reſt, ſufficeth for all; but if they be in ſeveral counties, there muſt be as many *liveries* as there are counties. If the lands be out on leaſe, though all lie in the ſame county, there muſt be as many *liveries* as there are tenants. In all theſe caſes it is prudent to endorſe the *livery of ſeiſin* on the back of the deed, ſpecifying the manner, time, and place of making it, together with the names of the witneſſes.

LIVERY, in *Law*, is where the fame is not made on the land, but only *in ſight* of it; the feoffor ſaying to the feoffee, "I give you yonder land, enter and take poſ-"ſeſſion." However, this *livery* in law cannot be given or received by attorney, but only by the parties themſelves.

Anciently, there were a pair of gloves, a ring, knife, an ear of wheat, &c. delivered in ſign of *livery* and *ſeiſin*.

LIVERYMEN *of London*, are a number of perſons choſen out of the freemen of each COMPANY. Out of this body the common-council, ſheriffs, aldermen, and other officers for the government of the city, are elected; and they only have the privilege of giving their votes in common-hall for members of parliament, &c. from which the reſt of the citizens are excluded. If any one of the company refuſe to become a *liveryman*, he may be fined, and an action of debt will lie for the ſum.

LIVERYMEN, in *Natural Hiſtory*, a name given by authors to a ſort of caterpillars, remarkable for their variety of colours. Theſe are of that claſs of caterpillars, which live in communities, and build themſelves neſts to defend them from the injuries of the weather. They may be ranked among the proceſſionary kinds, always following one another with great order in their marches; but what is moſt ſurpriſing, is to ſee them ſtraggle very far from their neſts, and this often, by ſeveral repeated windings and turnings, without loſing their way. Their art, in doing this, deſerves notice, and is the ſame by which Theſeus got out of the labyrinth of Crete. Phil. Tranſ. N° 470. p. 459.

Theſe creatures ſpin all the way they go. The firſt ſpins a thread as he crawls along, the ſecond follows him in the ſame track, and a third follows that, and ſo on, all ſpinning as they go; and their threads being all laid cloſe together, by means of their all purſuing the ſame track, they at length furniſh a fine ſhining track all the way they have gone. Theſe make a ſort of path, and ſeveral of theſe paths are ſeen running ſeveral ways from the neſt, which is the common center of them all. By means of theſe paths the creatures are able, at pleaſure, to run back directly to the neſt through all the ways they have gone from it.

If any one of theſe congeries of threads be broken in any part, all the caterpillars that are beyond that part, will be found at a terrible loſs, and running about in different directions, when they come to the place, without any knowledge of the true road to the neſt, till they are led by ſome one, who happens to find the way to the other broken end of the path, and by drawing his threads across the breach, unites the path again; as ſoon as this is done, all the reſt go on the ſame road, and arrive at the neſt.

LIVIA, in *Zoology*, a name given by ſome authors to a particular ſpecies of pigeon called *peleas* by the Greeks. It is very like the common pigeon in ſhape, but is ſomewhat ſmaller, its legs are red, and its beak white, except that it is a little purpliſh about the noſtrils.

It is all over grey, but that the ends of its tail-feathers are black, and there is a purpliſh and greenith variegation about the ſides and ſhoulders. And its wing-feathers have ſome white variegations, as has alſo the lower part of the neck. It is ſuppoſed by Mr. Ray, and ſome others, to be the ſame with the TASSAROLLA of the Italians, or *columba turbida*.

LIVONICA *terra*, in the *Materia Medica*, a kind of fine bole uſed in the ſhops of Germany and Italy, of which there are two ſpecies, the yellow and the red. The diſtinguiſhing characters of which are theſe.

The yellow Livonian earth is a pure and perfectly fine bole, of a ſhattery friable texture, conſiderably heavy, and of a dull duſky yellow, which has uſually ſome faint bluſh of reddiſhneſs in it. It is of a ſmooth ſurface, and does not ſtain the hands; it adheres firmly to the tongue, and melts freely in the mouth, leaving no gritlineſs between the teeth, and ferments not at all with acid menſtrua. In a moderate fire it acquires ſome additional hardneſs, and a darker colour. It is eſteemed a ſudorific and an aſtringent.

The red Livonian earth is an impure bole, of a looſe texture, and of a dull red. It is of a ſmooth ſurface, breaks eaſily between the fingers, and ſlightly ſtains the hands. It melts freely in the mouth, has a very ſtrongly aſtringent taſte, but leaves a gritlineſs between the teeth, and is alkaline. It acquires a conſiderable hardneſs in the fire, and becomes of a paler colour with a ſtrong caſt of yelloviſh-brown.

Theſe earths are both dug out of the ſame pit, in the place from whence they have their name, and in ſome other parts of the world. They are generally brought to us made up into little cakes, and ſealed with the impreſſion of a church, and an eſcutcheon with two croſs keys, and is recommended in diarrhœas, dyſenteries, &c.

LIVRE, a French money of account, conſiſting of twenty ſols; each ſol containing twelve deniers.

The origin of the word is derived hence, that anciently the Roman *libra*, or pound, was the ſtandard by which the French money was regulated; twenty ſols being made equal to the *libra*. By degrees the *libra* became a term of account; ſo that any coin juſt worth twenty ſols was a *livre*, or *libra*; and ſince the time of Charlemagne, all contracts have been made on the foot of this imaginary coin; though the ſols have frequently changed their weight and alloy.

The *livre* is of two kinds, *Tournois*, and *Pariſis*.

LIVRE *Tournois*, as above, contains twenty ſols Tournois, and each ſol twelve deniers Tournois.

LIVRE *Pariſis*, is twenty ſols Pariſis, each ſol Pariſis worth twelve deniers Pariſis, or fifteen deniers Tournois; ſo that a *livre Pariſis* is equivalent to twenty-five ſols Tournois; the word *Pariſis* being uſed in oppoſition to *Tournois*, on account of the rate of money, which was one fourth higher at Paris, than at Tours.

One penny ſterling was equal to thirteen and a half deniers Tournois; ſo that the Engliſh pound ſterling was equal to thirteen *livres* ſix ſols eight deniers, of French money; while the exchange was on the foot of fifty-four pence ſterling, to a French crown of ſixty ſols Tournois; which was the late par between England and France; but at preſent, the French crown is but equal to 27*d.* ſterling; on which footing the *livre* is but equivalent to 10*d.* ſterling. See COINS, and EXCHANGE.

There have ſince been pieces of gold ſtruck of twenty ſols value; and under Henry III. in 1575, pieces of ſilver of like value; both the one and the other were called *francs*; and thus the imaginary coin became real. It appears that the Romans alſo had a kind of money, which they called LIBRA, or *libella*; which was the tenth part of their denarius; ſo called, becauſe equivalent to an *as*, which, at firſt, weighed a *libra*, or pound of copper. Scaliger adds, that they uſed libra as a term of account, not as a coin: *Libra erat collecta ummorum, non ummus.*

LIXIVIOUS, LIXIVIAL, or LIXIVIATE, in *Chemiſtry*, is underſtood of ſalts extracted from burnt vegetables by lotion.

Lixivious ſalts are the fixed ſalts of plants, &c. extracted by exhaling the plants, or reducing them to aſhes, and afterwards making a lixivium of thoſe aſhes with water.

Mr. Boyle obſerves, that the difference between *lixivious* and common ſalts, conſiſts in this, that the former change the diſſolution of ſublimate in common water into a yellow colour, which the latter do not. See ALKALI and SALT.

LIXIVIUM, *ley*, a liquor made by the infuſion of wood-aſhes; and which is more or leſs pungent and penetrating, as it is more or leſs impregnated with ſalts, and fiery particles abounding therein.

What is left after the evaporation of such a liquor, is called a *lixivious salt*; such as all those are, which are made by incineration.

Lixiviums are of notable use, not only in medicine, but also in bleaching, sugar-works, &c. See BLEACHING, SUGAR, and POT-ASHES.

LIXIVIUM *martis*, in *Medicine*, a new form of medicine introduced into practice in the London Dispensatory. The manner of preparing it is to set the matter remaining in the retort after the sublimating the *flores martis*, in a damp place, where by means of the moisture of the air it will run into a liquor. See FLORES *martiales*, and IRON.

LIXIVIUM *saponarium*, *soap-lees*, a liquor now much used in medicine in cases of the stone; and when intended for this use, it is to be made something less strong than for the soap-boiler's use, and should be prepared in the following manner. Take Ruffia pot-ash, and quick-lime, of each an equal quantity; though pure alkaline salt requires commonly about twice its weight of quick-lime to render it completely caustic, which is known by the ley making no effervescence with acids: throw water on them by small quantities till the lime is fluked; then throw on more water, and ftir the whole together, fuffering it to ftand for a day or two, that the falt of the afhes may be diffolved; after fome time pour the liquor, filtered through paper, if neceffal, into another veffel. A true ftandard wine-pint of this liquor meafured with the greateft exactnefs, ought to weigh juft fixteen ounces Troy. If it be found on trial to be heavier than this, for every drachm it exceeds that weighs an ounce and a half of water is to be added to each pint: but if it be lighter than this, it muft be either boiled to this ftandard, or elfe poured upon frefh lime and afhes.

The makers of foft foap with us prepare their *lees* fo much ftronger than this, that to be reduced to this ftandard, it requires to be diluted with an equal quantity of fair water.

Quick-lime has the property of increafing confiderably the cauſticity of all fixed alkalis, by abforbing their fixable air or gas. See *Quick*-LIME.

This cauſtic ley evaporated to dryneſs, furniſhes an alkaline ſalt exceedingly acrid, which being melted in a crucible becomes what is called common CAUSTIC; becauſe when it is applied to the ſkin, it makes an eſchar, pierces it, and leaves an ulcer, the ſuppuration of which, when continued, is called an ISSUE. Cauſtic alkali has not only much greater diſſolving power, but is alſo much more deliquiſcent, and attracts much more powerfully the moiſture of the air, than ordinary alkali. This inconvenience is avoided by boiling down the ſoap ley only to one fourth part, and then, while the liquor continues boiling, ſprinkling in, by little and little, ſo much powdered quick-lime as will abſorb it ſo as to form a kind of paſte.

LIXIVIUM *tartari*, the name given in the London Diſpenſatory to the liquor called by moſt authors *oil of tartar per deliquium*. This is made of TARTAR, which is to be calcined to a whiteneſs, and then ſet in a damp place, where it will liquify by the moiſture of the air. The liquor thus procured is more pure than if the calcined tartar were diſſolved directly in water.

LIZARD, in *Aſtronomy*. See LACERTA.

LIZARD, in *Zoology*. See LACERTA.

LIZARD, *devil*. See MADOUJAS.

LIZARD, *fly-catching*. See GOBEMOUCH.

LIZARD'S *tail*, *ſaururus*, in *Botany*, a genus of the *hexandria tetragynia* claſs. Its characters are theſe: the flowers are diſpoſed in a katkin or tail; they have an oblong permanent empalement of one leaf; they have no petal, but have ſix long hair-like ſtamina, placed three on each ſide oppoſite, terminated by oblong erect ſummits; and an oval germen, with three lobes having no ſtyle, but crowned by three blunt permanent ſtigmas; the germen becomes an oval berry with one cell, including one oval ſeed. We have but one ſpecies in the Engliſh gardens, which is a native of North America, but is a plant of no great beauty. See PEPPER.

LIZIERE, the ſame with HERME, *foreland*, or *relais*.

When this ſpace is covered with a parapet, it is called a FAUSSE-*braye*, or low wall.

LLAMA, in *Zoology*. See GLAMA.

LLECH, the Welch name for a kind of monumental ſtone found in that country. See PILLAR.

LOACH, in *Ichthyology*, the Engliſh name of a fiſh, called alſo the *grendling*, and by the Germans the *ſmerle* or *ſmerling*. It is a ſpecies of the cobitis, and is diſtinguiſhed by Artedi, by the name of the *ſmooth-ſpotted cobitis* with a cylindric body.

LOAD, LODE, an Anglo-Saxon word, ſignifying *lead*, in *Mining*, is uſed, eſpecially in the tin-mines, for any regular vein or courſe, whether metallic or not; but moſt commonly *lode* means a metallic vein. See TIN.

It is to be obſerved, that mines in general are veins or cavities within the earth, whoſe ſides receding from or approaching to each other, make them of unequal breadths in different places, ſometimes forming large ſpaces, which are called *holes*; theſe holes are filled like the reſt with ſubſtances, which, whether metallic, or of any other nature, are called *loads*. When the ſubſtances forming theſe *loads* are reducible to metal, the *loads* are by the Engliſh miners ſaid to be alive, otherwiſe they are termed dead *loads*.

In Cornwall and Devonſhire the *loads* all hold their courſe from eaſtward to weſtward, though in other parts of England they frequently run from north to ſouth. The miners report, that the ſides of the *load* never bear in a perpendicular, but always overhang either to the north or ſouth above. The mines ſeem to have been ſo many channels, through which the waters paſs within the earth, and like rivers they have their ſmall branches opening into them, in all directions; theſe are by the miners termed the feeders of the *load*. Moſt mines have ſtreams of water running through them, and when they are found dry, it ſeems owing to the water having changed its courſe, which it ſeems ſometimes to have been compelled to by the *load*'s having filled up the courſe, and ſometimes to have fallen into other more eaſy channels. Phil. Tranſ. N° 401, p. 404. Price's Mineralogia Cornubienſis, 1778, p. 80, &c.

The *load* is frequently intercepted by the croſſing of a vein of earth, or ſtone, or ſome other metalline ſubſtance, in which caſe it generally happens, that one part of the *load* is moved to a conſiderable diſtance on one ſide. This tranſient *load* is, by the miners, termed a *ſtocking*; and the part of the *load* which is moved, is by them ſaid to be heaved. This fracture or heave of a *load*, according to Mr. Price ubi ſupra, p. 97, is produced by a ſubſidence of the ſtrata, from their primary poſitions, which he ſuppoſes to have been horizontal or parallel to the ſurface of the earth, and therefore ſhould more properly be called a depreſſion than a heave. This heaving of the *load* would be an inexpreſſible loſs to the miner, did not experience teach him, that as the *loads* always run on the ſides of the hills, ſo the part heaved is always moved toward the deſcent of the hill; ſo that the miner working toward the aſcent of the hill, and meeting a ſtocking, conſiders himſelf as working in the heaved part; wherefore, cutting through the ſtocking, he works upon its back up the aſcent of the hill, till he recovers the *load*, and *vice verſa*.

Sometimes, though not univerſally, the mine is lined with an intermediate ſubſtance between the *load* and itſelf. This is properly ſpeaking the wall of the *load*; though, in the common acceptation of that term, it ſignifies either ſuch intermediate ſubſtance, or the ſide of the mine where the *load* immediately unites itſelf to it. The ſprings in theſe parts are always hard, as they abound in ſtony or other mineral particles. From theſe particles, which are ſuſtained in large quantities in all theſe places, we frequently find the paſſages quite choaked up; the ſtony matter ſeparated from the water of the ſpring, gradually concreting to the walls of the mine, till it has in time blocked up the whole cavity, with a maſs of ſpar, of a coarſe texture and irregular figure: at other times this ſtony matter concretes more diſtinctly; in which caſe it ſeems to be governed in its formation by a plaſtic power, or peculiar modus of attraction, by which the particles before ſuſpended in the water are brought together under a peculiar form. This power in general ſo exerts itſelf over the harder particles of matter ſuſtained in the water, as to arrange them into the form of an hexangular pyramid, terminating an hexangular column of four, five, or more times its length. Thus is the common rock cryſtal formed; and when this power is unmoleſted, the columns of this body are carried to a great ſize.

Theſe cryſtals are of different tranſparences and colours, as the pure matter, of which they are compoſed, is more or leſs diſengaged from the mixture of foreign particles; or as thoſe, or other ſubſtances, are found capable of imparting theſe tinctures, or other qualities to them: but when the plaſtic particles are more numerous, there ſeems reaſon to believe that theſe very plaſtic particles, before they are fixed, are ſubject to the control and direction of any fixed plaſtic particle, within the verge of whoſe activity they happen to move. Notwithſtanding which, after they are once fixed, they exert their own plaſtic powers, and, in conjunction with the firſt plaſtic principle, govern the future concretion in ſuch manner, as to form a ſeemingly irregular cryſtal, though compoſed of two or more regular cryſtals.

Theſe cryſtalline concretions exert a ſtrong attraction on many metallic ſubſtances, ſo as frequently to contain lead, copper, and other metals, in very conſiderable quantities, embodied in them.

The waters of mines are, beſide cryſtal, impregnated alſo with

with a great quantity of sulphureo-saline particles, and these are in some of a vitriolic, and in others of an arsenical nature. The first of these, when pure, concrete into white cubes, resembling grains of silver; while the other, or arsenical sulphur, concretes into yellow cubes, resembling grains of pure gold. Both these concretions, whether single or in large confused clusters, are called by the miners *mundic*. The sulphureo-saline principle of concretion seems of the same nature with the plastic power in the formation of crystals; and these bodies, like the others, are in the same manner found sometimes simple, sometimes compound. On the sides of these the concretion may always be observed forming itself into threads, which in three sides run in different directions, but are always similar in the opposite sides. Phil. Trans. N° 401. p. 403. See MINERALOGY.

LOAD is also used for nine dishes of ore, each dish being about half a hundred weight.

LOAD, *master*, among *Miners*. See MASTER-*lead*.

LOAD, *turning a*. See TRAINING.

LOADING. See CARGO and LADING.

LOADMANAGE, in *Maritime Affairs*: the hire is sometimes so called, which the pilot of a ship receives of a master, for conducting a ship up the river, or into port.

LOADSTONE. See MAGNET.

LODESTONE, *floating*, an instrument invented and so called by Mr. Boyle, which he used to discover, whether guineas or other coins were counterfeit, by putting the instrument with the piece of coin to be tried and fastened to the bottom of it, into a tall glass or other vessel of water: marks being so made on the slender metalline pipe, which forms the upper part of the instrument, that the hollow ball which made the lower part of it, would sink much lower, at least two inches, if the coin be true gold, than if it be not: and according as the water reaches to one or other of the aforesaid marks, an estimate may be made, whether the piece of coin, if counterfeit, be made of tin, brass, copper, silver, or lead. The instrument might be applied to any coins, either of gold or silver, provided that they were of any considerable bulk. Birch's Hist. of the Royal Society, vol. iii. p. 115.

LOAM, in *Natural History*, the name of a class of fossile bodies, the characters of which are these: they are compound earths composed of dissimilar particles, hard, stiff, dense, harsh, and rough to the touch, not easily ductile while moist, readily diffusible in water, and usually composed of sand and a tough viscid clay.

Of this class there are two genera. 1. The THRAUSTOMICTRES; and, 2. The GLISCHROMICTRES. The first are composed of sand and a less viscid clay, and are of a friable or crumbly nature; the second are composed of sand and a more viscid clay, and are of a more tough and viscid texture. Hill's Hist. of Fossils.

Da Costa distinguishes them by their colour into black and white, which are not acted upon by acids; yellow *loams*, some of which are not acted upon by acids; and other alkaline, brown *loams*, some acted upon by acids, to which class belongs the Windsor *loam*, so well known and so much used for making bricks, building furnaces, flues, &c. and others alkaline; and the green *loams* not acted upon by acids. Hist. Fossils, p. 112, &c.

LOAM is also used for a sort of mortar made of this earth, by tempering it with water, straw, &c.

LOASA, in *Botany*, a genus of the *polyandria monogynia* class: the characters are, that the calyx is a five-leaved permanent perianthium; the corolla has five large and very wide petals; the staminæ are capillary filaments, longer than the nectarium, which is composed of five small leaves, the fruit is an oval germen, which becomes a single-celled, three-valved capsule, containing several small seeds; there is only one species.

LOBBY, in *Architecture*, is a small hall or waiting-room: it is also an entrance into a principal apartment, where there is a considerable space between that and a portico or vestibule, and the length or dimensions will not allow it to be considered as a vestibule or an anti-room. See ANTICHAMBER.

LOBE, *Λοβος*, among *Anatomists*, is applied to each of the two parts whereof the lungs consist.

This separation into *lobes* is of use in dilating the lungs, by causing them to receive more air, and preventing their being too much squeezed, when the back is bent. For this reason it is, that beasts, which are always inclining towards the earth, have more *lobes* in their lungs than men: even their *liver* is divided into *lobes*, whereas that of man is continued. See *Tab. Anat. Splanch. fig.* 14. *lit. d d*, &c. See LIVER.

LOBE is also used for the tip of the ear; which is more fat and fleshy than any other part thereof.

Du Laurent says, that the word *lobe*, in this last sense, comes from the Greek, *λοβεω, to shame*, or *be ashamed*; this part of the ear being said to blush when the person is ashamed.

LOBE is also used in speaking of fruits and grains.

Thus the bean consists of two equal parts, called *lobes*, which compose the body thereof, and are encompassed with the outer skin.—And all other grains, even the smallest, are divided, like the bean, into the two *lobes*, or equal parts; as Dr. Grew has shewn in his Anatomy of Plants.

LOBELIA, in *Botany*, a genus of the *syngenesia monogamia* class. Its characters are these: the empalement of the flower is indented in five parts; the flower has one petal, irregular, and the fruit is a capsule under the petal, with two cells, and two seeds: the species are twenty-eight according to Linnæus, who has joined this genus to the *Rapuntium*, or CARDINAL'S-flower of Tournefort, but Mr. Miller maintains that they should be distinguished.

LOBLOLLY, a sea-faring dish, otherwise called BURGOO.

LOBLOLLY-*boy*, in *Botany*. See GOUANIA.

LOBS, in *Mining*, are steps that ascend or descend within the mines, as stairs up to and down from a chamber.

LOBSTER, in *Zoology*, a species of the SQUILLA, according to some writers; but in the Linnæan system a species of the CANCER or CRAB. The common *lobster* is distinguished by a smooth thorax; short serrated snout; very long antennæ, and between them two shorter, bifid; claws and fangs large, the greater tuberculated, the lesser serrated in the inner edge; four pair of legs; six joints in the tail; and caudal fins rounded.

Lobsters inhabit all the rocky shores of our island, but chiefly in the deepest and clearest water at the foot of rocks that impend over the sea. In summer they are found near the shore, and thence to about six fathoms depth in water; in winter they are seldom taken in less than twelve or fifteen fathoms. They are brought in vast quantities from the Orkney isles, and many parts of the eastern coast of Scotland to the London markets. Sixty or seventy thousand are annually brought in well-boats, from the neighbourhood of Montrose alone. Some of them are taken by the hand; but most in pots, which are a sort of trap formed of twigs, and baited with garbage, resembling a wire mouse-trap, so that when the *lobster* gets in, there is no return. These are fastened to a cord sunk into the sea, and their place marked by a buoy. In the neighbourhood of Scarborough, the fishermen use a bag-net fixed to an iron hoop, about two feet in diameter, and suspended by three lines like a scale, and baited with fish guts tied to the bottom and middle of the net. They are caught in the night, and seldom in the day, unless the water be thick and opake. *Lobsters* begin to breed in the spring, and continue breeding most part of the summer. They propagate *more humano*, and are extremely prolific. Dr. Baster counted twelve thousand four hundred and forty-four eggs under the tail, besides those that remained in the body, unprotruded. See *Fecundity of Fish*. These eggs are deposited in the sand, where they are soon hatched. When they first appear under the tail of the female or hen *lobster*, they are very small and black; but become as large as ripe elder-berries before they are deposited, and change into a dark-brown colour. When she deposits her eggs, she is said to be in berry; and this is the case at all times of the year, but chiefly in winter; though they seem to come to life only during the warm summer months of July and August. *Lobsters* change their cruft annually; but the female does not cast her shell in the same year in which she deposits her eggs. Previous to this change, they appear sick, languid, and restless: they acquire a new coat in a few days; and whilst the shell is soft, they seek some lonely place for security, and they only grow in size when their shells are membranous and soft. *Lobsters* and CRABS will also renew their claws in a few weeks, if they are torn off by accident. They are said to fear thunder and any great noise, and are apt to cast their claws on such occasion. When frightened, they will spring tail-foremost, from a considerable distance to their hold in the rock; the fishermen can by them pass about thirty feet, and by the swiftness of their motion, suppose they may go much farther. They are more active in warm weather than cold.

The large *lobsters* are generally in their best season from the middle of October, till the beginning of May. Many of the small ones, and some few of the larger sort, are good all the summer. They are chosen for the table, by their being heavy in proportion to their size, and by the hardness of the shells on their sides, which, in perfection, will not yield to moderate pressure. Barnacles and other small shell-fish adhering to them, shew likewise their superior goodness. Cock-*lobsters* are in general better than the hens in winter: they are distinguished by the narrowness of their tails, and by their having a strong spine upon the centre of each of the transparent processes beneath the tail, which support the four middle plates

of

of their tails. The fifh of a *lobfter*'s claw is more tender, delicate, and eafy of digeftion than that of the tail. Pennant's Brit. Zool. vol. iv. p. 9. &c.

The fhell calcined and drank in wine, is faid to break and carry off concretions in the kidneys; and it is likely enough to have fome effect in fuch cafes, becaufe the fhells of fifh calcined, are a fort of lime; and the falts of lime are the grand diffolvents of ftony concretions. It is now well known, that whatever good effects Mrs. Stevens's medicine for the ftone may have, are owing to the falts of lime. See LIME-*water*, and LITHONTHRIPTICS.

Lobfters, as a food, are highly alcalefcent, and of conſequence muſt be very proper when an acid acrimony prevails in the ſtomach and general habit: but the contrary in caſe of a tendency to an alcaline putrefactive. They are eſteemed very nouriſhing and good in a conſumption. James.

LOBULE, LOBELLUS, in *Anatomy*, a little *lobe*.

Each lobe of the lungs is divided into ſeveral leſſer lobes, or *lobules*, which are faſtened on each ſide, to the largeſt branches of the trachea.—Each *lobule* conſiſts of a great number of little round veſicles, which have all a communication with one another. It is into theſe veſicles that the air enters, by the trachea, in inſpiration; ſtill quitting them again in expiration. See *Tab. Anat. (Splanch.) fig. 14. lit. f f*, &c.

LOBUS *echinatus*, in the *Materia Medica*, a name by which ſome authors have called the *burdock*, or bonour-nut

LOCAL, ſomething ſuppoſed to be tied or annexed to ſome particular place.

Thus, in *Law*, a thing is ſaid to be *local*, i. e. annexed or fixed to the freehold.—An action of treſpaſs for battery, &c. is tranſitory, not *local*; that is, it is not neceſſary that the place where battery was committed, ſhould be ſet down as material in the declaration; or if it be ſet down, the defendant cannot traverſe it, by ſaying, he did not commit the battery in the place mentioned in the declaration, and ſo avoid the action.

LOCAL, *choſe*. See CHOSES.

LOCAL *cuſtoms*, are thoſe peculiar to ſome lordſhip, or other diſtrict, and not agreeable to the general cuſtoms of the country. See CUSTOM.

LOCAL, *treſpaſs*. See TRESPASS.

LOCAL *problem*, in mathematics, is ſuch an one, as is capable of an infinite number of different ſolutions; becauſe the point, that is to ſolve it, may be indifferently taken within a certain extent; e. gr. any where in ſuch a line, within ſuch a plane figure, &c. which is called a *geometrical locus*.

A *local problem* may be either *ſimple*, as when the point ſought is in a right line; *plane*, as when the point ſought is in the circumference of a circle; *ſolid*, as when the point required is in the circumference of a conic ſection; or *ſurſolid*, as when the point is in the perimeter of a line of a *higher kind*, as the geometers call it.

LOCAL, or *artificial memory*. See MEMORY.

LOCAL *colours*, in *Painting*, are ſuch as are natural and proper for each particular object in a picture.

They are ſo called, to diſtinguiſh them from the clair obſcure, which conſiſts wholly of black and white.

LOCAL *motion*. See MOTION.

LOCATION, in the *Civil Law*, an act by which any thing is let out, on rent.

The ſecond title of the nineteenth book of the *Digeſt* is on the ſubject of *location* and conduction. *Location* and *conduction* are relative terms, and are uſed as well for the action of him that lets, as for that of him who takes on that letting.

LOCATION, *tacit*, is, when the perſon who takes, continues on the premiſes beyond the term of his leaſe; which, by the civil law he is allowed to do, at leaſt for the ſpace of a year, on the ſame terms.

LOCH, in the *Materia Medica*, a name given by Avicenna, and others to the gum lac. They call it alſo *keikem* and *kenkem*, and are too apt to confound it with the CANCAMUM, ſandarach, and other gums, with which they made their ſeveral ſorts of varniſh.

LOCH, or LOHOCH, in *Pharmacy*, a compoſition of a middle conſiſtence between a ſyrup and a ſoft electary; chiefly uſed for diſeaſes of the lungs.

The word is originally Arabic; but continues ſtill in uſe among the apothecaries.

The Latins call it *linctus*, and the Greeks, λειχὼν, becauſe the manner of taking it is by licking.

LOCHE, or *Sea*-LOCHE, a name uſed in ſome parts of England for the MUSTELA, called in other places, particularly in Cornwall, the WHISTLE-*fiſh*.

LOCHIA, or LOCHES, Λοχία, the evacuations conſequent on the delivery of a woman in child-bed.

As ſoon as the uterus is eaſed of its load, its fibres, as alſo thoſe of the peritonæum, the muſcles of the abdomen, &c. which have been extremely diſtended during the laſt period of geſtation, begin to contract themſelves, and their veſſels; particularly the uterus, which by this means expels the blood amaſſed in it.

The flux of the *lochia*, or of blood and humours from the uterus, about the time of parturition, is of two kinds; the one called *legitimate*, which happens after the excluſion of the foetus, as its proper time; the other *abortive*, which attends miſcarriages, and does not indeed follow them, but either precedes, or happens immediately in the act of abortion, and that uſually in a very violent and terrible manner. The legitimate is alſo often too copious.

Signs of it. The legitimate *lochial* flux is an excretion of blood from the genitals for eight, ten, twelve, or fourteen days after child-birth, and ſometimes for a longer time than that. During the firſt days, pure blood, grumous, and coagulated, is diſcharged, or at leaſt a fluid coloured with blood; after the fourth or fifth day, this diſcharge is attended with a diſagreeable, and ſometimes with a plainly foetid ſmell; in the ſucceeding days the humour becomes leſs bloody, and more and more yellowiſh, and after this it gradually becomes pale and watery, till it loſes all colour and ſmell: all this while alſo the flux becomes more and more moderate in quantity, till at length it wholly ceaſes of itſelf. This is the natural ſtate of this flux; but if the fecundines are too long retained, or if a part of them be torn off and left in the uterus, then the flux frequently exceeds its due bounds, and many pains and ſpaſtic motions are felt about the uterus, and throughout the abdomen.

In the *lochial* fluxes attending abortions, the blood uſually flows out gently and moderately before the act, then it comes on, during the excluſion of the foetus, with great violence. Sometimes alſo, when violent paſſions of the mind have preceded, it comes on with all this violence at the firſt attack, before the foetus is excluded; this is followed by the foetus, or falſe conception, whichever is in the uterus; and this is attended uſually with faintings, and with violent pains in the belly. Perſons ſubject to frequent abortions, have leſs trouble and pain with them than others, and the *lochial* flux is with them in leſs quantity.

The too great flux of the *lochia* is a thing of dangerous conſequence, and the perſons principally ſubject to it are thoſe of plethoric habits, and ſuch as are ſubject to violent paſſions; ſuch as are uſed to much wine, or other ſtrong liquors, and to high-ſeaſoned foods, as alſo ſuch as have omitted bleeding at the proper times during their being with child, and ſuch as have been accuſtomed to too copious fluxes of the menſes. In caſes of abortions, thoſe are moſt of all ſubject to immoderate fluxes of them, who have not been duly treated, or properly purged and cleanſed, after a former lying in. The principal occaſions of large fluxes of the *lochia* after child-birth, are either a plethoric habit, or the uſe of violent medicines to promote delivery, or the retention of part of the fecundines in the uterus.

Prognoſtics from it. The flux of the *lochia*, when moderate and regular, is of the utmoſt benefit to the perſon, and the ſuppreſſion of it is ever attended with danger. This is, of all other fluxes of blood, the moſt ſubject to exceed the uſual quantity; and in abortions, after the third month of pregnancy, is uſually greater than in parturitions at the full time. When this flux is immoderately great, the patient's ſtrength is conſumed by it in a very little time; and when it is not thus violent for a continuance, but returns, after ſhort intervals, with violent effects, it is a ſign that the womb is not properly cleanſed, and the perſon is afterwards frequently either barren, or ſubject to repeated abortions. In caſes of a threatened abortion, when there has once been a copious diſcharge of blood, there ſhould be no attempt made to retain the foetus in its place.

Method of treating. When the flux of the *lochia* is moderate, it requires no aſſiſtance from the phyſician, but nature is to be left to her own courſe; if they flow too immoderately, the patient ſhould be laid with her head low, kept cool, and the ſame means are to be uſed as in caſes of violent fluxes of the UTERUS. If the flooding proves violent, linen cloths, which have been wrung out of a mixture of equal parts of vinegar and water, or red wine, ſhould be applied to the belly, the loins, and the thighs: theſe muſt be changed as they grow dry; and may be diſcontinued as ſoon as the flooding abates. The medicines which have power to quiet the violent emotions of the blood are to be often repeated, ſuch are nitre, the alkaline abſorbents, as crabs eyes, and the like, and a little cinnabar: if theſe are inſufficient, recourſe is to be had to the milder aſtringents, ſuch as the *crocus martis antimoniatus*, and tincture of ſalt of ſteel, and the decoction, or extract of the common yarrow. In a violent flooding after delivery, Dr. Buchan ſays, that he has ſeen very good effects from the following mixture. Take of penny-royal water, ſimple cinnamon-water, and ſyrup of poppies,

pies, each two ounces, acid elixir of vitriol, a dram; mix them and take two table-spoonfuls every two hours, or oftener, if neceſſary. The abortive flux of the *lochia* is to be treated in the ſame manner with the too violent one attending parturition at the full time. The abortion is always to be haſtened, and the fœtus, mole, or whatever, to be taken out as ſoon as poſſible, when the flux becomes violent, leſt the patient faint and periſh under it. The way to prevent an immoderate flux of the *lochia* in parturition, is to bleed often during the time of pregnancy, and, if neceſſary, this may be done even juſt before delivery. The proper ligatures on the belly, after the exceluſion of the fœtus, are alſo of great ſervice in this view, and the keeping perfectly quiet, and avoiding much talking, are greatly conducive to it. The return of abortions is principally guarded againſt by a ſufficient cleanſing of the womb at the time, and by bleeding in the arm about that time of pregnancy at which the abortion happened before.

Child-bearing women are to be conſidered, after parturition, as wounded perſons, in whom fevers are very eaſily brought on, and every thing that makes any commotion in the blood is to be carefully avoided by them. Aſtringent medicines are to be avoided as much as poſſible in theſe caſes; and where they are found abſolutely neceſſary, the milder only are to be given, and attemperating medicines muſt always be given between; and if this is neglected, inflammatory fevers, hectics, and often dropſies, are the conſequence.

LOCHIA, *ſuppreſſion of the*. Theſe are either plenary or partial. In the plenary ſuppreſſion there is no blood diſcharged at all, or if there was a beginning of a proper diſcharge, it ſtops during the firſt day. In the partial ſuppreſſion, or, as it is called by ſome writers, *the imminution of the lochia*, they keep their period of eight, ten, or twelve days, but are in ſo ſmall a quantity, as to be ſcarce allowable under the name of a flux of this kind. In the judging of this imminution, it is neceſſary to conſider the natural ſtate and conſtitution of the patient; and if in the time of her not being pregnant, ſhe has been uſed but to ſmall diſcharges by the menſtrual flux, there is not to be expected a large flux of the *lochia*; if the perſon has had children before, inquiry is alſo to be made into the quantity diſcharged at thoſe times, and from that is to be determined what is to be expected. The perſons ſubject to *ſuppreſſions of the lochia* are principally thoſe of a plethoric habit, and whoſe veins are ſmall; thoſe who are of a timid diſpoſition, and eaſily ſubject to fear, ſorrow, and the like paſſions. Theſe are principally the natural cauſes of a *ſuppreſſion of the lochia*, but to theſe are to be joined many accidental and adventitious ones; ſuch as the ſudden cooling of the body, the giving very forcing medicines to forward the delivery, and the improper uſe of hot medicines. Theſe are often given to promote the *lochia*, when they are judged not to flow in ſufficient quantity, and they often produce a plenary ſuppreſſion of them, inſtead of a cure. Myrrh, ſaffron, and the volatile ſalts, when given injudiciouſly, are of this tribe. Sometimes alſo ſuppreſſions of them are brought on by violent paſſions, and by the repeated and forcible efforts the perſon has been obliged to make during a hard labour.

Prognoſtics from it. There is no kind of hæmorrhage, the ſuppreſſion of which is attended with ſuch great or ſuch imminent danger, as this of the *lochia*. The natural ſuppreſſions are uſually either from too great a quantity of blood, with a ſpiſſitude of it, or from a turgeſcence and violent emotion of it. In the firſt caſe, the ſymptoms which ſucceed are leſs violent, in the latter they are more terrible. Of the firſt kind are inquietude, toſſing and turning about, anxiety, and ſtraitneſs of the præcordia, pains of the head, and want of appetite. In the latter caſe, fevers of the inflammatory kind often immediately enſue, and ſometimes miliary and purple fevers, with great malignity; ſome alſo immediately fall into delirions of the moſt violent kinds, and into quinſies. Such are the ſudden effects of theſe ſuppreſſions; but beſide theſe, there are often left coagulations, or grumos of blood in the uterus; theſe prevent future conception, or prevent the fœtus, when conceived, from receiving due nouriſhment, and bring on, by that means, abortion; and when this is not the caſe, they ſubject the patient to various hyſteric and convulſive diſorders, and frequent faintings.

Method of cure. When the ſuppreſſion is but partial, and the *lochia* to flow, though in too ſmall a quantity; in this caſe the more gently ſtimulating medicines are to be given, and even theſe only in very ſmall doſes. The tincture of myrrh and ſaffron, and eſſence of amber, may in this caſe be mixt and given, twenty, or twenty-five drops at a doſe twice a day: theſe often have a very ſpeedy and happy effect. When the ſuppreſſion is plenary, and eſpecially when it has already held the patient ſome days, it is in vain to expect to bring on a regular diſcharge of them at once by ſtimulating medicines; the cauſes of the ſuppreſſion are then to be enquired into, and the febrile emotions of the blood allayed by febrifuges, and by nitrous medicines; and when the blood is reſtored to its proper ſtate, they will again begin to flow regularly. The common method of bleeding to bring them on again, is ſeldom attended with much ſucceſs; when indeed the patient has omitted bleeding at proper times during pregnancy, this ſometimes proves ſerviceable; but rarely when the blood is faulty in quality, rather than in quantity. The generality of the world are afraid of nitre in theſe caſes, leſt it ſhould bring on diarrhœas, but it is only an immoderate uſe of it, that is liable to this objection; for given in doſes of four, five, or ſix grains, it will rather prevent, than occaſion a diarrhœa in theſe caſes. Junker's Conſp. Med. p. 6c, &c. Buchan's Dom. Med. p. 584, &c. See DELIVERY, and INFLAMMATION *of the womb*.

LOCHIAL *fevers*, a term uſed by medical writers to expreſs ſuch fevers as ariſe from ſuppreſſions or imminutions of the *lochial* diſcharges in lying-in women, or from any other irregularities during the time of that diſcharge. Junker's Conſp. Med. p. 252.

LOCIS *communibus*. See COMMUNIBUS.

LOCK, a little inſtrument uſed for the ſhutting and faſtening of doors, cheſts, &c. only to be opened by a key. The *lock* is reckoned the maſter-piece in ſmithery; a great deal of art and delicacy being required in contriving and varying the wards, ſprings, bolts, &c. and adjuſting them to the places where they are to be uſed, and to the various occaſions of uſing them.

From the various ſtructure of *locks*, accommodated to their different intentions, they acquire various names. Theſe placed on outer doors are called *ſtock-locks*; thoſe on chamber-doors, *ſpring-locks*; thoſe on trunks, *trundle-locks*, *pad-locks*, &c.

Of theſe, the *ſpring-lock* is the moſt conſiderable, both for its frequency, and the curioſity of its ſtructure. Its principal parts are, the main-plate, the cover-plate, and the pin-hole: to the main-plate belong the key-hole, top-hook, croſs-wards, bolt-toe or bolt-nab, drawback ſpring tumbler, pin of the tumbler, and the ſtaples; to the cover-plate belong the pin, main-ward, croſs-ward, ſtep-ward, or dap-ward; to the pin-hole belong the hook-ward, main croſs-ward, ſhank, the pot or bread, bow-ward, and bit.

LOCK, or WEIR, in *Inland Navigation*, the general name for all thoſe works of wood or ſtone, made to confine and raiſe the water of a river: the banks alſo which are made to divert the courſe of a river, are called by theſe names in ſome places. But the term *lock* is more particularly appropriated to expreſs a kind of canal incloſed between two gates; the upper called by workmen the ſluice-gate, and the lower called the flood-gate. Theſe ſerve in artificial navigations to confine the water, and render the paſſage of boats eaſy both in paſſing up or down the ſtream.

To LOCK, in *Fencing*, is to ſeize your adverſary's ſword-arm, by twining your left arm round it, after you cloſe your parade, ſhell to ſhell, in order to diſarm him.

LOCKER, in a *Ship*, a kind of box or cheſt made along the ſide of a ſhip, to put or ſtow any thing in.

LOCKER, *Gaz. Lam.* See HELLEBORE, and TROLLIUS.

LOCKER, *ſhot*, in *Sea Language*. See GARLAND.

LOCKMAN, in the Iſle of Man, the officer who executes the orders of the government, much like our under-ſheriff.

LOCKS, in the *Manege*, in French called *entraves*, are pieces of leather two fingers broad, turned round, and ſtuffed on the inſide, to prevent their hurting the paſtern of a horſe, round which they are clapped. An *entrave* is compoſed of two *entraves* joined by an iron chain, ſeven or eight inches long.

LOCKSPIT, among *Miners*, is the ſmall cut, or trench, made with a ſpace of about a foot wide, to mark out the firſt lines of a work.

LOCRIAN, in *Ancient Muſic*, the ſeventh ſpecies of the DIAPASON. It was alſo called *hypodorian*, and *common*.

LOCULAMENTUM, in *Botany*, denotes a cell or partition, in a ſeed-pod, for the SEED of a plant.

In ſome plants, we only find one *loculamentum* in a pod; in others two, three, or more.

LOCUS, *place*, in the general ſenſe. See PLACE.

LOCUS, among *Ancient Muſicians*, was uſed to ſignify the interval between one degree of acuteneſs, or gravity of ſound, and another. The Greeks uſed the word *τονος* in the ſame ſenſe, for the ſpace through which the voice moved. See MOTION.

This motion the Greeks diſtinguiſhed into two kinds; one continued, *τονος*, the other diſjunct, *διαστημα*.

Inſtances of the firſt kind are in ſpeaking; of the ſecond, in ſinging; and this they called melodic motion, or what was adapted to ſinging. Ptolemy in like manner divides ſounds of unequal pitch, *φθογγοι διαστηματικοι*, into continued and diſcrete, and ſays the firſt kind are improper, and the ſecond proper, for harmony.

Ariſtides Quintilianus interpoſes a third kind of motion between the two here mentioned, ſuch as that of a perſon reciting a poem.

LOCUS, the *boxthorn*, in *Botany*, is uſed by ſome for the tree whoſe juices afford us the gum anime of the ſhops. See LUCUS-*arbores*.

LOCUS, in *Rhetoric*, a topic, or head, whence arguments are brought to prove the queſtion in hand. Some of theſe are called *loci communes*, or common topics, as being common to all ſorts of arguments: thus, whether a thing be poſſible or impoſſible, more or leſs than ſomething elſe, &c.

Beſides theſe, three others are mentioned by rhetoricians, *perſons*, *acts*, and *circumſtances*; to which ſome add *circumdion*; but Voſſius will have this laſt to be comprehended under *acts*. See TOPIC.

LOCUS *geometricus* denotes a line, by which a local or indeterminate problem is ſolved. See LOCAL *problem*.

A *locus* is a line, any point of which may equally ſolve an indeterminate problem.

Thus, if a right line ſuffice for the conſtruction of the equation, is called *locus ad rectum*; if a circle, *locus ad circulum*; if a parabola, *locus ad parabolam*; if an ellipſis, *locus ad ellipſim*; and ſo of the reſt of the conic ſections.

The *loci* of ſuch equations as are right lines, or circles, the ancients called *plain loci*; and of thoſe that are parabolas, hyperbolas, &c. *ſolid loci*.

Wollius, and other moderns, divide the *loci* more commodiouſly into orders, according to the number of dimenſions to which the indeterminate quantities riſe. Thus it will be a *locus of the firſt order*, if the equation be $x=ay$; a *locus of the ſecond* or quadrate order, if $y^2=ax$, or $y^2=a^2-x^2$, &c. a *locus of the third* or cubic order, if $y^3=a^2x$, or $y^3=ax^2+x^3$, &c.

The better to conceive the nature of the *locus*, ſuppoſe two unknown and variable right lines AP, PM (*Vide Analyſis, fig.* 29, 30.) making any given angle APM with each other; the one whereof, as AP, we call x, having a fixed origin in the point A, and extending itſelf indefinitely along a right line given in poſition; the other PM, which we call y, continually changing its poſition, but always parallel to itſelf; and moreover an equation only containing theſe two unknown quantities x and y, mixed with known ones, which expreſſes the relation of every variable quantity AP (x) to its correſpondent variable quantity PM (y): the line paſſing through the extremities of all the values of y, i. e. through all the points M, is called a *geometrical locus*, in general, and *the locus* of that equation in particular.

All equations, whoſe *loci* are of the *firſt order*, may be reduced to ſome one of the four following formulæ:

1. $y=\frac{bx}{a}$, 2. $y=\frac{bx}{a}+c$. 3. $y=\frac{bx}{a}-c$. 4. $y=c-\frac{bx}{a}$,

where the unknown quantity y is ſuppoſed always to be freed from fractions, and the fraction that multiplies the other unknown quantity x, to be reduced to this expreſſion $\frac{b}{a}$, and all the known terms to this c.

The *loci* of the firſt formula being already determined; ſince it is evident, that it is a right line which cuts the axis in A, and which makes with it an angle, ſuch that the two unknown quantities x, y, may be always to one another in the proportion of a to b; to find that of the ſecond, $y=\frac{bx}{a}+c$; in the line AP (*fig.* 31.) take AB $=a$, and draw BE $=b$, AD $=c$, parallel to PM. On the ſame ſide AP, draw the line AE of an indefinite length towards E, and the indefinite ſtrait line DM parallel to AE. I ſay the line DM is the *locus* of the aforeſaid equation, or formula; for if the line MP be drawn from any point M thereof parallel to QA, the triangles ABE, APF, will be ſimilar; and therefore AB (a): BE (b) :: AP (x): PF $=\frac{bx}{a}$; and conſequently PM (y) $=$ PF $\left(\frac{bx}{a}\right)+$FM ($c$).

To find the *locus* of the third form, $y=\frac{bx}{a}-c$, proceed thus. Aſſume AB $=a$ (*fig.* 32.) and draw the right lines BE $=b$, AD $=c$, parallel to PM, the one on one ſide AP, and the other on the other ſide; and through the points A, E, draw the right line AE of an indefinite length towards E, and through the point D, the line DM parallel to AE; I ſay, the indefinite right line GM ſhall be the *locus* ſought; for we ſhall have always PM (y) $=$ PF $\left(\frac{bx}{a}\right)-$FM c.

Laſtly, to find the *locus* of the fourth formula, $y=c-\frac{bx}{a}$ *i. e.* $a:b::c:\frac{bx}{a}$ in AP (*fig.* 33.) take AB $=a$, and draw BE $=b$, AD $=$ C, parallel to PM, the one on one ſide AP, and the other on the other ſide; and through the points A, E, draw the line AE indefinitely towards E, and through the point D draw the line DM parallel to AE. I ſay DG ſhall be the *locus* ſought; for if the line MP be drawn from any point M thereof, parallel to AQ, then we ſhall have always PM (y) $=$ FM (c) $-$ PF $\left(\frac{bx}{a}\right)$.

Hence it appears, that all the *loci* of the firſt degree are ſtrait lines; which may be eaſily found, becauſe all their equations may be reduced to ſome one of the foregoing formulæ.

All *loci* of the *ſecond* degree are conic ſections, viz. either the parabola, the circle, ellipſis, or hyperbola: if an equation therefore be given, whoſe *locus* is of the ſecond degree, and it be required to draw the conic ſection, which is the *locus* thereof; firſt draw a parabola, ellipſis, and hyperbola; ſo, as that the equations expreſſing the natures thereof may be as compound as poſſible; in order to get general equations, or formulæ, by examining the peculiar properties whereof we may know which of theſe formulæ the given equation ought to have regard to; that is, which of the conic ſections will be the *locus* of the propoſed equation. This known, compare all the terms of the propoſed equation with the terms of the general formula of that conic ſection, which you have found will be the *locus* of the given equation; by which means you will find how to draw the ſection, which is the *locus* of the equation given.

For example: let AP (x), PM (y), be unknown, and variable ſtrait lines (*fig.* 34.) and let m, n, p, r, s, be given right lines: in the line AP take AB $=m$, and draw BE $=n$, AD $=r$, parallel to PM; and through the point A draw AE $=s$, and through the point D the indefinite right line DG parallel to AE. In DG take DC $=s$, and with CG, as a diameter, having its ordinates parallel to PM, and the line CH $=p$, as the parameter, deſcribe a parabola CM; and it will be the *locus* of the following general formula:

$$yy-\frac{2n}{m}xy+\frac{nn}{mm}xx-2ry+\frac{2nr}{m}x+rr=0.$$
$$-\frac{sp}{m}x+ps.$$

For if from *any* point M there be drawn the right line MP, making any angle APM with AP; the triangles ABE, APF, ſhall be ſimilar; therefore AB (m): AE (s) :: AP (x): AF or DG $=\frac{sx}{m}$; and AB (m): BE (n) :: AP (x): PF $=\frac{nx}{m}$. And conſequently GM or PM $-$PF$-$FG $=y-\frac{nx}{m}-r$, and CG or DG$-$DC $=\frac{sx}{m}-s$. But from the nature of the parabola GM^2 $=$ CG $\times$ CH; which equation will become that of the general formula, by putting the literal values of thoſe lines.

Again: if through the fixed point A you draw the indefinite right line AQ (*fig.* 35.) parallel to PM, and you take AB $=m$, and draw BE $=n$, parallel to AP, and through the determinate points A, E, the line AE $=s$; and if in AP you take AD $=r$, and draw the indefinite ſtrait line DG parallel to AE, and take DC $=s$; this being done, if with the diameter CG, whoſe ordinates are parallel to AP, and parameter the line CH $=p$, you deſcribe a parabola CM; this parabola ſhall be the *locus* of this ſecond equation, or formula:

$$xx-\frac{2n}{m}yx+\frac{nn}{mm}yy-2rx+\frac{2nr}{m}y+rr=0.$$
$$-\frac{sp}{m}y+ps.$$

For if the line MQ be drawn from any point M, therein, parallel to AP; then will AB (m): AE (s) :: AQ or PM (y): AF or DG $=\frac{sy}{m}$. And AB (m): BE (n) :: AQ (y): QF $=\frac{ny}{m}$. And therefore GM or QM $-$QF$-$FG $=x-\frac{ny}{m}-r$; and CG or DG$-$DC $=\frac{sy}{m}-s$. And ſo by the common property of the parabola, you will have the aforegoing ſecond equation, or formula. So likewiſe may be found general equations, or formulæ, to the other conic ſections.

Now if it be required to draw the parabola, which we find to be the *locus* of this propoſed equation $yy - 2ay - bx + cc = 0$; compare every term of the firſt formula with the terms of the equation, becauſe yy in both is without fractions; and then will $\frac{2n}{m} = 0$, becauſe the rectangle xy not being in the propoſed equation, the ſaid rectangle may be eſteemed as multiplied by 0; whence $n = 0$, and $m = 1$; becauſe the line AE falling in AB, that is, in AP in the conſtruction of the formula, the points B, E, do coincide. Therefore, deſtroying all the terms affected with $\frac{n}{m}$ in the formula, and ſubſtituting m for 1, we ſhall get $yy - 2ry - px + rr + pt = 0$. Again, by comparing the correſpondent terms $-2ry$, and $-2ay$, as alſo $-px$, and $-bx$, we have $r = a$, and $p = b$; and comparing the terms wherein are neither of the unknown quantities x, y, we get $rr + pt = cc$; and ſubſtituting a and b for r and p, then will $s = \frac{cc - aa}{b}$, which is a negative expreſſion, when a is greater than c, as is here ſuppoſed. There is no need of comparing the firſt terms yy and yy, becauſe they are the very ſame. Now the values of m, n, r, p, t, being thus found, the ſought *locus* may be conſtructed by means of the conſtruction of the formula, and after the following manner.

Becauſe BE $(n) = 0$ (*fig.* 36.) the points B, E, do coincide, and the line AE falls in AP; therefore through the fixed point A draw the line AD $r = a$ parallel to PM, and draw DG parallel to AP, in which take DC $(s) = \frac{aa - cc}{b}$; then with DC, as a diameter, whoſe ordinates are right lines parallel to PM, and parameter the line CH $(p) = b$, deſcribe a parabola: I ſay, this will be the *locus* of the given equation, as is eaſily proved. If in a given equation, whoſe *locus* is a parabola, xx be without a fraction; then the terms of the ſecond formula muſt be compared with thoſe of the given equation.

Thus much for the method of conſtructing the *loci* of equations which are conic ſections. If, now, an equation, whoſe *locus* is a conic ſection, be given; and the particular ſection whereof it is the *locus*, be required:

All the terms of the given equation being brought over to one ſide, ſo that the other be equal to 0, there will be two caſes.

Caſe 1. When the rectangle xy is not in the given equation. 1. If either yy or xx be in the ſame equation, the *locus* will be a parabola. 2. If both xx and yy are in the equation with the ſame ſigns, the *locus* will be an ellipſis, or a circle. 3. If xx and yy have different ſigns, the *locus* will be an hyperbola, or the oppoſite ſections regarding their diameters.

Caſe 2. When the rectangle xy is in the given equation. 1. If neither of the ſquares xx or yy, or only one of them, be in the ſame, the *locus* of it will be an hyperbola between the aſymptotes. 2. If yy and xx be therein, having different ſigns, the *locus* will be an hyperbola, regarding its diameters. 3. If both the ſquares xx and yy are in the equation, having the ſame ſigns, then, according as the co-efficient of x^2 is greater, equal or leſs than the ſquare of half the co-efficient of xy, the *locus* ſhall be an ellipſe, parabola, or hyperbola. And in any caſe the *locus* of the equation is ſome conic ſection.

This method of conſtructing geometrical *loci*, by reducing them to equations as compound as poſſible, we owe to Mr. Craig, who firſt publiſhed it in his Treatiſe of the Quadrature of Curves, in 1693. It is explained at large in the ſeventh and eighth books of the Conic Sections of the marquis de l'Hoſpital. See this ſubject particularly illuſtrated in Maclaurin's Algebra, part ii.

LOCUST, *locuſta*, a genus of inſects, comprehending the *locuſt*, ſimply ſo called, the ſeveral ſpecies of other *locuſts* and graſhoppers, with the crickets of the houſe and field. Linnæus has claſſed all theſe under the genus of GRYLLUS.

Willughby obſerves, that in theſe animals there are always more males than females, which is contrary to the order of nature in other inſects, where the females are much the moſt numerous; and Swammerdam obſerves, that it is only the males that make a noiſe, which he ſays they do by a ſwift vibration of their wings, either againſt one another, or againſt their legs. See *Tab. of Inſects*, N° 3. fig.

The nymphæ, or worm of the *locuſt*, ſcarce at all differs from the creature in its perfect ſtate. It moves and eats in the nymph ſtate; and all the viſible difference is, that the wings are not expanded as in the perfect *locuſt*, but are gathered up in a ſmall compaſs, and form four little buttons on the ſhoulders. Swammerdam obſerves, that the want of attention to this particular in former writers had been the occaſion of a very unneceſſary multiplication of names; as Aldrovand, Johnſon, Mouffet, and others, have deſcribed theſe *locuſts* in the nymph ſtate under the names of *bruchi*, *attelabi*, and *aſeli*, ſuppoſing them to be ſo many diſtinct ſpecies of animals. It is obſerved, that toward the end of ſummer the males are very tender of the females, three or four of them being frequently ſeen gathered about one of that ſex, and ſeeming to do her all the kind offices in their power, fluttering about with their wings, and rubbing her with their fore-legs. The males are always more briſk and nimble than the females; and among all the kinds of *locuſts*, there are a great many naturally imperfect; particularly many have only one hinder leg, yet theſe hop almoſt as well as the reſt. Swammerd. Bibl. Natur.

We have in England but very few inſects of this kind. The ſpecies mentioned by Mr. Ray are ſeven.

1. The common ſmall green graſhopper. This has articulated antennæ, very flexile, and nearly half an inch long; its belly is green; its outer wings brown, and its inner ones membranaceous, tranſparent, and reticulated; its back is divided into eight or nine rings, and is of a browniſh colour; the hinder legs are very long, and ſtrong. There is a great variety in the colour of this ſpecies; ſome have more, ſome leſs green, and ſome have a little yellow about them. 2. The larger grey-winged graſhopper. This is diſtinguiſhed by having grey wings ſpotted with black. 3. The ſmall brown graſhopper, with a long rhomboidal head; the antennæ in this ſpecies are very ſhort. 4. The great green graſhopper. This is accurately deſcribed by Joan. de Muralto in the German Ephemerides, and Mr. Ray has taken the whole into his hiſtory: the antennæ are long and ſlender, the eyes black and prominent, and the breaſt is remarkably high and narrow. 5. The great Spaniſh *locuſt*, of a browniſh grey, with ſpotted wings: this is about three inches long, and is the ſpecies lately found in England. 6. The great African *locuſt*, with ſtriated ſhoulders: this differs from the former only in theſe ſtreaks. 7. The great African *locuſt*: this is four inches long, and is of a green colour; under the ſhoulders there are only ſmall rudiments of wings, and it has two ſtrong yellow forceps under the tail, which terminate in black points. Theſe ſpecies of this genus, commonly called *crickets*, ſee under the article CRICKET. Ephem. Germ. anno 12. obſ. 16. Ray's Hiſt. Inſ. p. 64. See alſo CICADA and HARVEST *fly*.

The country of the Coſſacks or Ukrain is, in dry ſummers, much infeſted with ſwarms of *locuſts*, driven thither by an eaſt or ſouth-eaſt wind. The number of theſe inſects is ſo great, that they darken the air, and devour all the corn of the country. They lay their eggs in autumn, and then die. It is ſaid that each of theſe creatures lays two or three hundred eggs, which hatching the enſuing ſpring, produce ſuch a number of *locuſts*, that they do far more miſchief than before, unleſs the rains fall, which kill both the eggs and the inſects, or unleſs a ſtrong north, or north-weſt wind ariſes, which drives them all into the Euxine ſea. The hogs of the country are fond of theſe eggs, and devour great quantities of them. In the night, when theſe inſects reſt on the ground, they cover it to the height of three or four inches. If a wheel paſs over them, they emit an intolerable ſtench. Phil. Tranſ. N° 8. p. 137. where Monſieur Beauplan's Deſcription of Poland, and Thevenot's Voyages, part i. are referred to.

Graſhoppers ſometimes come in ſwarms to particular places in the ſame manner that *locuſts* do. They appeared ſome years ago in Languedoc, and ſome other places, in very formidable ſwarms, and eat up all the harveſt of ſeveral years. They took their flight like birds, and were about an inch long, and of a grey colour, in ſhape wholly like the common graſhoppers. They were found in many places covering the whole ſurface of the earth four or five inches deep, and uſed to lie quiet till toward noon; but when the ſun then ſhone warmly upon them, they uſed to riſe and take wing, and ſettling on the corn-fields, they would in a few hours eat up the whole produce, ears, leaves, and even the more tender parts of the ſtalks.

When they had deſtroyed one field in this manner, they uſed to take wing and fly to another. They uſually flew very high in the air, and directly againſt the wind; but as ſoon as they ſaw a new crop of corn, they dropped together in a ſwarm, and cleared it as they had done the firſt. This practice they continued the whole day, and toward evening they ſettled upon the ground, where they remained quiet, till the heat of the following day raiſed them again. When they had deſtroyed all the corn in the country, they ſeized upon the vines, garden herbs, and willows, and at laſt upon the hemp, whole fields of which

which they eat up, notwithſtanding its great bitterneſs. Towards autumn they left off feeding, and were found in copulation, and ſoon after this the females were every where ſeen laying their eggs, which they depoſited in the ground, making a hole with their tail large enough to receive a gooſe quill.

In theſe holes every female would lay forty or fifty eggs, each of the ſize of a millet ſeed; and when they had finiſhed the laying, they covered up the hole to keep out the water; after this they died apace, and the multitudes of their carcaſes ſtunk intolerably, poiſoning the air. The next year they hatched in April; and from this one ſwarm there were ſuch prodigious numbers hatched, that fifteen tuns of them were deſtroyed, while no bigger than flies, and nine tuns of their eggs before the hatching, and yet there remained enough of them to deſtroy, in a great meaſure, the ſucceeding harveſt. After this they gradually decreaſed for ſeveral years, till they were not more numerous there than elſewhere. This was attributed to the induſtry of the farmers in killing them; but it is more probable, that unfavourable ſeaſons deſtroyed them. Phil. Tranſ. N° 182. p. 146.

LOCUST, *water, lentiſa aquatica*, the name given by authors to a ſpecies of water-inſect, ſomewhat reſembling the *locuſt* kind in ſhape. It is about three inches long, its tail an inch and quarter, and its legs are of different lengths; the anterior part being the ſhorteſt of all; its body is ſlender, and its fore-legs are always carried ſtrait forward, ſo as to reach beyond the head in the form of antennæ; theſe, as well as the other legs, end each in two claws; the eyes are ſmall, and not very prominent, and the upper wings are cruſtaceous; the under ones membranaceous, thin, and tranſparent; the middle joint of the leg is ſuch, that the creature can only move them upwards, not downwards, and there runs an acute tongue or proboſcis under the belly, as is the caſe in the water-ſcorpion and notonecta.

LOCUST, in *Botany*. See CAROB. See alſo HONEY-*flower*.

LOCUST-*tree, hymenæa*, in *Botany*, a genus of the *decandria monogynia* claſs. Its characters are theſe: the outward involucrum of the flower is divided into two parts, the inner is of one leaf, indented in five parts; the flower has five equal petals, and ten ſhort declining ſtamina; in the center is ſituated an oblong germen, which becomes a large oblong pod, with a thick ligneous ſhell, divided tranſverſely into ſeveral partitions; in each of which is lodged one compreſſed large ſeed, ſurrounded with a farinaceous pulp. We know but one ſpecies of this tree, which is a large ſpreading tree in the Weſt Indies, the wood of which is eſteemed good timber; it yields a fine clear reſin, which is the GUM *anime* of the ſhops, and makes an excellent varniſh.

LOCUST-*tree, honey*. See HONEY *locuſt*.

LOCUSTA-*pulex*, a name given by Swammerdam to a genus of inſects, deſcribed ſince by Mr. Ray under the name CICADULA.

LOCUSTÆ, is uſed by botaniſts for the tender extremities of the branches of trees; ſuch as, it is ſuppoſed, John the Baptiſt fed on in the wilderneſs.

Some alſo uſed *locuſtæ* for the beards and pendulous ſeeds of oats, and of the gramina paniculata; to which the name is given on account of their figure, which ſomething reſembles that of a locuſt.

LOCUSTELLA, the *graſs-hopper lark*, in *Ornithology*, the name of a ſmall bird of the lark-kind, the *alauda trivialis* of Linnæus. It is ſmaller than the common wren, and of a browniſh-yellow colour, ſpotted with black; its tail is long and brown, and its belly and thighs are variegated with oblong ſtreaks of a blackiſh brown; its legs are very long, ſlender, and brown; it feeds on flies, and makes the ſame ſort of noiſe that the graſshopper does, only much louder; and uſually, as it ſings, ſits on the ſummit of ſome prickly ſhrub, and vibrates its wing about very briſkly; in the midſt of ſummer it chirps the whole night, and ceaſes about the latter end of July.

LOCUTIUS, in *Mythology*, the god of ſpeech among the Romans, called by Livy *Aius Locutius*.

LOCUTORIUM. The monks and other religious in monaſteries, after they had dined in their common hall, had a withdrawing-room, where they met and talked together among themſelves, which room, for that ſociable uſe and converſation, they called *locutorium, a loquendo*; as we call ſuch a place in our houſes parlour, from the French *parler*; and they had another room, which was called *locutorium foriſecum*, where they might talk with laymen.

LODESMAN, or LODMAN, a pilot eſtabliſhed for conducting veſſels in and out of harbours, or up and down navigable rivers. See PILOT.

LODGMENT, in *Military Affairs*, ſometimes denotes an encampment made by an army.

LODGMENT is more frequently uſed for a work caſt up by the beſiegers, during their approaches, in ſome dangerous poſt, which they have gained, and where it is abſolutely neceſſary to ſecure themſelves againſt the enemies fire; as in a covert-way, in a breach, the bottom of a moat, or any other poſt gained from the beſieged.

Lodgments are made by caſting up earth, or by gabions, or paliſades, woolpacks, faſcines, mantelets, or any thing capable of covering ſoldiers in the place they have gained, and are determined to keep.

LOEFLINGIA, in *Botany*, a genus of the *triandria monogynia* claſs. Its characters are theſe: the calyx is compoſed of five leaves; the flower has five very ſmall petals; and the fruit is a ſingle-celled capſule, with three valves. There is only one ſpecies.

LOESELIA, in *Botany*, the name of a genus of plants of the *didynamia angioſpermia* claſs, called alſo *rezenia* by Houſtun. The characters are theſe: the periantkium is one-leaved, and tubular; it is ſhort, and divided into four ſegments, and remains after the flower is fallen; the flower conſiſts of one irregular petal; it is formed into a tube at the length of the cup, and itsverge is divided into five equal ſegments, all bending toward one ſide, and of an oval figure; the ſtamina are four filaments, of the length of the flower; two of theſe are ſhorter than the others; the antheræ are ſimple, and the germen of the piſtil is oval; the ſtyle is ſimple, the ſtigma thick, the capſule is of an oval figure, divided into three cells, and containing a number of ſeeds of an angular figure.

LOG, in the *Jewiſh Antiquities*, a meaſure which held a quarter of a cab, and conſequently five-ſixths of a pint. There is mention of a *log*, 2 Kings vi. 25. under the name of a *fourth part of a cab*. But in Leviticus the word *log* is often met with, and ſignifies that meaſure of oil, which lepers were to offer at the temple after they were cured of their diſeaſe.

Dr. Arbuthnot ſays, that the *log* was a meaſure of liquids, the ſeventy-ſecond part of the bath or ephah, and twelfth part of the hin, according to all the accounts of the Jewiſh writers.

LOG, a ſea-term, ſignifying a ſmall piece of timber of a triangular, ſectoral, or quadrantal figure, on board a ſhip, generally about a quarter of an inch thick, and five or ſix inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed upon the arch, or circular ſide, ſo as to ſwim perpendicularly in the water, with about two-thirds immerſed under the ſurface.

LOG-*line*, a little cord, or line, about a hundred and fifty fathoms long, faſtened to the *log*, by means of two legs, one of which paſſes through a hole at the corner, and is knotted on the oppoſite ſide, while the other leg is attached to the arch by a pin fixed into another hole, ſo as to draw out occaſionally. By theſe legs the *log* is hung in equilibrio; and the line thus annexed to it is wound round a reel fixed for that purpoſe in the gallery of the ſhip.

This line, from the diſtance of about ten, twelve, or fifteen fathom off the *log*, has certain knots or diviſions, which ought to be at leaſt fifty feet from each other; though it was the common practice at ſea, not to have them above forty-two feet aſunder.

The length of each knot ought to be the ſame part of a ſea-mile as half a minute is of an hour; and admitting the meaſurement of Mr. Norwood, who makes a degree on a great circle of the earth to contain 367,200 Engliſh feet, or about 69½ Engliſh ſtatute miles, and, therefore, 1/8th of it, or a nautical mile, will be 6120 feet; 1/120th of 6120, or 51 feet, ſhould be the length of each knot. But becauſe it is ſafer to have the reckoning rather before the ſhip than after it, therefore fifty feet may be taken as the proper length of each knot. The knots are ſometimes made to conſiſt only of forty-two feet each, even in the preſent practice; and this method of dividing the *log-line* was founded on the ſuppoſition that ſixty miles, each of 5000 Engliſh feet, made a degree; for 1/10 of 5000 is 41⅔, or, in round numbers, 42 feet. Mariners, rather than quit the old way, though known to be erroneous, uſe glaſſes for half minute ones, that run but 24 or 25 ſeconds. They have alſo uſed a line of 25 feet to 30 ſeconds, or a glaſs of 28 ſeconds to 42 feet. When this is the caſe, the diſtance between the knots ſhould be corrected by the following proportion: as 30 is to 50, ſo is the number of ſeconds of the glaſs to the diſtance between the knots upon the line. The heat or moiſture of the weather has often a conſiderable effect upon the glaſs, ſo as to make it run ſlower or faſter; it ſhould, therefore, be frequently tried by the pendulum in the following manner. On a round nail hang a ſtring that has a muſket-ball fixed to one end, carefully meaſuring between the center of the ball and the ſtring's loop over the peg 39⅛ inches, being the length of a ſecond pendulum; then ſwing it, and count one for every time it paſſes under

the

the peg, beginning at the second time it passes, and the number of twings made during the time the glass is running out, shews the seconds it contains. The line also is liable to relax and shrink, and should, therefore, be occasionally measured.

The use of the *log* and *line* is, to keep account, and make an estimate of the ship's way, or distance run; which is done by observing the length of line unwound in half a minute's time, told by a half-minute glass; for so many knots as run out in that time, so many miles the ship sails in an hour. Thus, if there be four knots veered out in half a minute, the ship is computed to run four miles an hour.

The author of this device for measuring the ship's way is not known; and no mention of it occurs till the year 1607, in an East-India voyage, published by Purchas; but from that time its name occurs in other voyages among his collections; and henceforward it became famous, being taken notice of both by our own authors, and by foreigners; as by Gunter in 1623; Snellius, in 1624; Metius, in 1631; Oughtred, in 1633; Herigone, in 1634; Saliocthal, in 1636; Norwood, in 1637; Fournier, in 1643; and almost by all the succeeding writers on navigation of every country.

Log, *to heave the*, as they call it, they throw it into the water, on the lee-side, letting it run, till it comes without the eddy of the ship's wake; then one, holding a half-minute glass, turns it up just as the first knot, or the mark from which the knots begin to be reckoned, runs off the reel, or passes over the stern. As soon as the glass is out, the reel is stopped, and the knots run off are told, and their parts estimated.

It is usual to heave the *log* once every hour in ships of war and East India men; and in all other vessels, once in two hours: and if at any time of the watch the wind has increased or abated in the intervals, so as to affect the ship's velocity, the officer generally makes a suitable allowance for it at the close of the watch.

The *log* is a very precarious way of computing, and must always be corrected by experience, and good sense; there being a great deal of uncertainty in the yawing of the ship going with the wind aft, or upon the quarter, in the heaving of it, by its coming home, or being drawn after the ship, on account of the friction of the reel, and lightness of the *log*, in the course of the current, and in the strength of the wind, which seldom keeps the same tenor for two hours together; which is the interval between the times of using the *log*, in short voyages, though in longer ones they heave it every hour. Yet is this a much more exact way of computing than any other in use; much preferable certainly to that of the Spaniards and Portuguese, who guessed at the ship's way, by the running of the froth or water by the ship's side; or to that of the Dutch, who used to heave a chip over-board, and to number the paces they walk on the deck, while the chip swims between any two marks, or bulk-heads on the side.

The above mentioned errors, and particularly the *log*'s being subject to drive with the motion which the water may have at its surface, whereas the experiment requires it to be fixed in the place where it is when the mark commencing the knots goes off the reel, have been considered by writers, and many methods have been proposed to remove, or at least to lessen them. The late M. Bouguer proposed a method, which has been thought deserving of particular attention, in the Mem. Acad. Sc. 1747; afterwards in his Treatise on Navigation, published at Paris in 1753, and since reprinted in 1760, by the abbé de la Caille. For this purpose, take for the *log* a conical piece of wood, which fix to the *log-line* passed through or along its axis, at about forty, fifty, or sixty, or more feet, from one end; and to this end fit the diver, which is a body formed of two equal square pieces of tin, or of thin iron plate, fixed at right angles to one another along their diagonals; and its size to fitted to that of the cone, that the whole may float. A cone of three inches diameter in the base, and of six inches in the slant height, is proposed by M. Bouguer to suit a diver made of plates about 9½ inches square; the intersection of the diagonals is joined to the *log-line*, and the loop and peg fixed as in the common *log*. However, it has been found, that no kind of wood used in Britih dock-yards, when formed into a cone of the above dimensions, will float a diver made of stout tin plates, one side of the square being 9½ inches. Such a diver weighing 1½ lb. avoirdupoise, required to float it a cone of five inches diameter, and twelve inches on the slant side, to as the point of the cone, which was made of light fir, should just appear above the water. Now supposing one side of such a square tin diver to be about ten inches, and made of plates only two-thirds of the thickness of the former, such a diver would weigh, with its solder, about twenty ounces, and can be floated by a light fir cone of four inches diameter in the base, and ten inches in the slant height or length; and such a compound *log* might, perhaps, be found on trial to be affected by about as much again as that proposed by M. Bouguer, and consequently the difference between the numbers given by the common *log*, and compound *log*, must be augmented by two-thirds of itself for the necessary correction, as below. When the compound *log* of Bouguer, above described, is hove overboard, the diver will sink too deep to be much affected by the current, or motion of the water at the surface; and the *log* will thereby keep more steadily in the place where it first fell; and, consequently, the knots run off the reel, will shew more accurately the ship's rate of sailing. As the common *log* is affected by the whole motion of the current, so that compound *log* will feel only a part thereof, viz. such a part nearly as the resistance of the cone is of the resistance of the diver; then the resistances of the above cone and diver are about as 1 to 5; and consequently this *log* will drive but one-fifth part of what the common *log* would do; and so the ship's true run will be affected by one-fifth part only of the motion of the waters. To obtain the true rate of sailing, it will be proper to heave alternately hour and hour, the common *log*, and this compound *log*; then the difference of their knots run off, augmented by its one-fourth part, is the correction; which applied to the knots of the common *log*, will give the ship's true rate of sailing, at the middle time between the hours when these *logs* were hove. The correction is additive, when the compound *log*'s run is the greatest, otherwise it is subtractive. To find the course made good: increase the observed angle between the *log-lines* by one-fourth part; and this gives the correction to be applied to the apparent course, or the opposite of that shewn by the common *log*; the correction is to be applied to the $\left\{\begin{matrix}\text{right}\\\text{left}\end{matrix}\right\}$ of the apparent course, when the bearing of the common *log* is to the $\left\{\begin{matrix}\text{left}\\\text{right}\end{matrix}\right\}$ of the compound *log*. Or thus: the lengths run off both *logs*, together with their bearings being known; in a card or compass apply the knots run off taken from a scale of equal parts along their respective bearings, from the center; join the ends, and in this line produced, on the side next the compound *log*'s length, take one-fourth of the interval; then a line drawn from the end, thus produced, to the center of the card, will shew the true course and distance made good. When a current, such as a tide, runs to any depth, the velocity of that current may be much better ascertained by the compound *log* than by the common one, provided the diver does not descend lower than the run of the current; for as those ships which are deepest immerged, drive fastest with the tide; so the diver, by being acted on below, as well as the *log* on the surface, their joint motion will give the total effect of the current's motion better than what could be derived from the motion at the surface only. Also by such a compound *log*, the depth to which any current runs, may be easily tried. Robertson's Nav. book ix. § 1.

We have an account in the Voyage to the North Pole, p. 97. of two other *logs*, which were tried by captain Phipps: one invented by Mr. Russel, the other by Foxon; both constructed upon this principle, that a spiral, in proceeding in its own length in the direction of its axis through a resisting medium, makes one revolution round the axis; if, therefore, the revolutions of the spiral are registered, the number of times it has gone its own length through the water will be known. In both these the motion of the spiral in the water is communicated to the clock-work within-board, by means of a small line, fastened at one end to the spiral, which rows it after the ship, and at the other to a spindle, which sets the clock-work in motion. That invented by Mr. Russel has a half-spiral of two threads, made of copper, and a small dial with clock-work, to register the number of turns of the spiral. The other *log* has a whole spiral of wood with one thread, and a larger piece of clock-work, with three dials, two of them to mark the distance, and the other divided into knots and fathoms, to shew the rate by the half-minute glass for the convenience of comparing it with the *log*. This kind of *log* will have the advantage of every other in smooth water and moderate weather; and it will be useful in finding the time of a ship when alone, in surveying a coast in a single ship, or in measuring distances in a boat between head-lands and shoals; but it is subject to other inconveniences, which will not render it a proper substitute for the common *log*.

Log-*board* is a table divided into four or five columns, wherein are marked the reckonings of every day; from whence they are entered into the *log-book* or traverse-book; whence it may be transcribed into the journals, and how much the ship gains in her course be estimated daily.

In

in the firſt column of the *log-board* is entered the hour of the day, from the noon of one day to the noon of the next; in the ſecond and third, the number of knots and fathoms the ſhip is found to run per hour, ſet againſt the hours when the *log* was hove; in the fourth, the courſes which the ſhip ſteers; and in the fifth, or right hand column, the winds, the alteration of the ſails, the buſineſs doing aboard, obſervations made of the weather, variation of the compaſs, &c. See JOURNAL.

LOG-*book*, at ſea, a book ruled and columned like the *log-board*. It is uſed by ſome to enter the *log-board*'s account in, every day at noon, with the obſervations then made; and from hence it is corrected and entered into the JOURNALS. The intermediate diviſions or watches of the *log-book*, containing four hours each, are uſually ſigned by the commanding officer in ſhips of war, or Eaſt India men.

LOG-*wood*, in *Botany*, the wood of a tree, called by Ray *arbor ſiliquoſa floribus papilionaceis*. It is deſcribed by Breynius under the name of *triſtis pavonis coronillæ folio ſecundo*, and *erythroxylum indicum ſpiniſſimum coluteæ ſolitis, floribus luteis, ſiliquis maximis*. Linnæus calls it *hæmatoxylon*, and makes it a genus of the *decandria monogynia* claſs. Its characters are theſe: the flower hath a permanent empalement, cut into five oval ſegments, and has five oval petals, and ten awl-ſhaped ſtamina, which are longer than the petals; in the center is ſituated an oblong, oval germen, which becomes an obtuſe, compreſſed capſule, with one cell, opening with two valves, containing two or three oblong, flat, kidney-ſhaped ſeeds. We know but one ſpecies of this genus, which grows naturally in the bay of Campeachy, at Honduras, and other parts of the Spaniſh Weſt Indies. The wood of this tree is brought to Europe, where it is uſed for dying purples, and for the fineſt blacks; and therefore it is a very valuable commodity.

The uſe of *log-wood* in dying was eſtabliſhed in this country by 13 & 14 Car. II. cap. 11. before which time it was prohibited as a pernicious material. *Log-wood* is uſed in miniature painting, to make a purple waſh; which may be varied to a more red or blue colour by the addition or omiſſion of BRASIL-*wood*. The waſh may be prepared by boiling an ounce of ground *log-wood* in a pint of water, till one half of the fluid be waſted; ſtrain it then through flannel, while of a boiling heat; and add to it, when ſtrained, about ten grains of pearl-aſhes. To make it more red, add half an ounce of Braſil-wood, or in proportion as the colour wanted may require; uſing in this caſe the pearl-aſhes very ſparingly.

Beſides its uſe among dyers, it is found to be an excellent aſtringent, and is given, in doſes of from ten grains to a ſcruple and upwards, with ſucceſs, in form of extract, obtained by inſpiſſating the decoctions, in diarrhœas, dyſenteries, and other diſorders proceeding from the laxity of the ſolids. To promote the extraction, the wood ſhould be reduced into a fine powder, which is to be boiled in the water, in the proportion of a pound to a gallon, till half the liquor is waſted. Some digeſt the powdered wood in as much ſpirit as will cover it to the height of about four inches, and afterwards boil it in water; the matters taken up by the watery and ſpirituous menſtrua may be united into one extract, by inſpiſſating the watery decoction to the conſiſtence of honey, and then gradually ſtirring in the ſpirituous tincture.

LOGARITHMIC, *azimſpherical*, is a curve (*Tab. II. Aſtroſyſt. fig.* 56.) deſcribed in the following manner; let the point C repreſent the center of the earth, CA the earth's ſemidiameter, and AB any height above the ſurface; at A place a right line AD, of any finite length, at right angles with AC. In the right line AC, towards C, take A*β* ſuch, that CA may be to A*β* in the proportion of CB to BA. In a right line drawn through *β*, at right angles with AC, take *β*E, of ſuch length, as to be to AD in the proportion of the denſity of the air at B to the denſity at A, the earth's ſurface. The curve, which the point E always touches, is a *logarithmic*, of which AC is the aſymptote; and is called by Dr. Horſley the *azimſpherical logarithmic*.

Imagine this curve deſcribed, and take another height A*b*, and take $A\zeta = \frac{CA \times Ab}{CB}$, and draw *ζε* parallel to *β*E, meeting the curve in *ε*. Then *βζ* is the logarithm of the ratio of *β*E to *ζε*, or of the denſity at B to the denſity at *b*. But if the greater of the two heights, AB and A*b*, bear but a very ſmall proportion to the ſemidiameter of the earth, their difference B*b* will be very nearly equal to *βζ*.

For, becauſe CB : BA = CA : A*β* (by conſtruction)
Therefore, by converſion, CB : CA = CA : C*β*.
In like manner, and by inverſion, CA : C*b* = C*ζ* : CA.
by equi-diſtance perturbate, CB : C*b* = C*ζ* : C*β*.

and converting, CB : B*β* = C*ζ* : *βζ*
by permutation, B*b* : *βζ* = CB : C*β*.

But when AB is infinitely diminiſhed, CB = CA ultimately. Alſo A*b* being infinitely diminiſhed, C*ζ* = C*b* ultimately. Therefore CB = C*ζ* ultimately, and B*b* = *βζ* ultimately. Q. E. D.

Now AB and A*b* will always be ſo ſmall, with reſpect to CA, if B and *b* be ſuppoſed to repreſent any acceſſible places, that CB, C*ζ*, and B*b*, *βζ*, may always, in this caſe, be conſidered as in their ultimate proportion of equality.

It is ſtill therefore to be admitted, as a principle, in practice, that the difference of elevation of any two places, is as the difference of the tabular logarithms of the height of the quickſilver in the barometer at the ſame time, at both places; that is, it is the logarithm of the ratio of thoſe heights in *ſome* ſyſtem of logarithms. And the heights of the quickſilver being given, by obſervation, the difference of elevation will be known, if that particular ſyſtem can be determined; that is, if the *modulus* of the ſyſtem, or the length of the ſubtangent of the curve DE of that ſyſtem, can be aſcertained, in ſome known meaſure, as Engliſh fathoms, or Paris toiſes.

The eaſieſt method of doing this, that theory ſuggeſts, is to compare barometers at two ſtations, ſuppoſe B and *b*, each at a known elevation AB and A*b*, above the level of the ſea. For the logarithms of any given ratio, in different ſyſtems, are proportional to the ſubtangents; and the difference of elevation, B*b*, diminiſhed in the proportion of CB, (the diſtance of the higher ſtation from the earth's center) to C*ζ*, (a third propotional to C*b*, the diſtance of the lower ſtation from the earth's center, and CA, the earth's ſemidiameter) is the logarithm of the ratio of the denſity at B, to the denſity at *b* (that is, of the columns of quickſilver ſuſtained in the barometer at B and *b*) in the atmoſpherical ſyſtem. Therefore, as the difference of the tabular logarithms, of theſe columns, to the ſubtangent of the tabular ſyſtem, ſo ſhould B*β*, diminiſhed as hath been ſaid (that is, ſo ſhould *βζ*) be to the ſubtangent of the atmoſpherical *logarithmic*. The utmoſt height, to which we can aſcend, above the level of the ſea, is ſo ſmall, that the reduction of B*b* may, even in this inveſtigation, always be neglected. For, if AB were four Engliſh miles, which exceeds the greateſt acceſſible heights, even of the Peruvian mountains, and AC three, *βζ* would be ſcarce one part in 500 leſs than B*b*. So that, by comparing barometers at different elevations, within a mile above the level of the ſea, the ſubtangent of the atmoſpherical curve might be determined, as it ſhould ſeem, without ſenſible error, by taking ſimply the difference of elevation, without reduction, for the logarithm of the ratio of the obſerved heights of the quickſilver in the atmoſpherical ſyſtem.

This ſubtangent is different in length at different times; though M. de Luc has ſhewn, that it is conſtant in a given temperature; ſo that if the temperature of the air is +16½ of his ſcale, the difference of the tabular logarithms of the heights of the quickſilver in the barometer, gives the difference of elevation in 100ths of a Paris toiſe; whence the number, which is the *modulus* of Briggs's ſyſtem, expreſſes the length of the ſubtangent of the atmoſpherical curve, ſuch as it is in that temperature, in 100ths of a Paris toiſe. Phil. Tranſ. vol. lxiv. part 1. p. 231, &c.

LOGARITHMIC, or *logarithmical*, relating to logarithms.

Thus we ſay, *logarithmic* arithmetic, curve, line, ſcale, ſpiral. See ARITHMETIC, &c.

LOGARITHMS, formed from the Greek λογος, *ratio*, and αριθμος, *number*; q. d. *ratio of numbers*; the indices of the ratios of numbers one to another; or a ſeries of artificial numbers proceeding in arithmetical proportion, correſponding to as many others proceeding in geometrical proportion; contrived for the eaſing and expediting of calculation.

LOGARITHMS have been uſually defined *numerorum proportionalium æquidifferentes termines*; but this definition Dr. Halley and Stifelius think deficient, and more accurately define them, *the indices or exponents of the ratios of numbers*; ratio being conſidered as a quantity *ſui generis*, beginning from the ratio of equality, or 1 to 1 = 0; and being affirmative when the ratio is increaſing, and negative when it is decreaſing.

Thus, if unity be made the common conſequent of all ratios, or the common ſtandard, to which all other numbers are to be referred, then every *logarithm* will be the numeral exponent of the ratio of its natural number to unity. E. g. the ratio of 81 to 1 contains the four following ratios, viz. that of 81 to 27, 27 to 9, 9 to 3, and 3 to 1, or $\frac{81}{27} \times \frac{27}{9} \times \frac{9}{3} \times \frac{3}{1}$; but all theſe ratios are equal to one another, and $3^4 = 3 \times 3 \times 3 \times 3$: conſequently the *logarithm* of 81 is four times as great as

that of 3. In the same manner, the ratio of 24 to 1, or $\frac{24}{1} = \frac{8}{1} \times \frac{3}{1} \times \frac{1}{1}$; and, therefore the *logarithm* of 24 is equal to the sum of the *logarithms* of 2, 3, and 4. And, universally, the magnitude of the ratio of A to 1, is to the magnitude of the ratio of B to 1, as the *logarithm* of A to the *logarithm* of B. Hence we derive a method of measuring all ratios whatever, let their consequents be what they will: e. g. the ratio of A to B is the excess of the ratio of A to 1, above the ratio of B to 1; therefore the numeral exponent of the ratio of A to B, will be the excess of the numeral exponent of the ratio of A to 1, above the numeral exponent of the ratio of B to 1, that is, the excess of the *logarithm* of A above the *logarithm* of B: therefore the magnitude of the ratio of A to B is to the magnitude of the ratio of C to D as the excess of the *logarithm* of A above the *logarithm* of B, which is the measure of the former ratio, is to the excess of the *logarithm* of C above that of D, which is the measure of the latter ratio; and thus we see that *logarithms* are as true and proper measures of ratios, as circular arcs are of angles. See the sequel of this article.

The nature and genius of *logarithms* will be easily conceived, from what follows:—a series of quantities increasing or decreasing according to the same ratio is called a *geometrical progression*; e. g. 1. 2. 4. 8. 16. 32, &c. A series of quantities increasing or decreasing, according to the same difference, is called an *arithmetical progression*; e. gr. 3. 6. 9. 12. 15. 18. 21. Now, if underneath the numbers proceeding in a geometrical ratio, be added as many of those proceeding in the arithmetical one, these last are called the *logarithms* of the first.

Suppose, e. g. two progressions:

Geomet.	1.	2.	4.	8.	16.	32.	64.	128.	256. 512.
Arithmet.	0.	1.	2.	3.	4.	5.	6.	7.	8. 9.

Logarithms.

0 will be the *logarithm* of the first term 1; viz. 1; 5, of the 6th, 32; 7 the *logarithm* of the 8th, 128, &c.

These indices or *logarithms* may be adapted to any geometric series; and, therefore, there may be as many kinds of indices or *logarithms*, as there can be taken kinds of geometric series; but the *logarithms* most convenient for common use, are those adapted to a geometrical series increasing in a ten-fold progression, as in the sequel.

The doctrine and use of *logarithms* may be conceived from the following propositions.

1. *If the* logarithm *of unity be* 0, *the* logarithm *of the factors or product will be equal to the sum of the* logarithms *of the factors.*—For as unity is to one of the factors, so is the other factor to the product. So that the *logarithm* of the product, is a fourth equidifferent term to the *logarithm* of unity, and those of the factors; but the *logarithm* of unity being 0, the sum of the *logarithms* of the factors must be the *logarithm* of the factum, or product. Q. E. D. Hence, since the factors of a square are equal to each other, i. e. a square is the factum or product of its root multiplied into itself, the *logarithm* of the square will be double the *logarithm* of the root.

In the same manner it appears, that the *logarithm* of the cube is triple; of the biquadrate, quadruple; of the fifth power, quintuple; of the sixth, sextuple, &c. of the *logarithm* of the root.

Unity, therefore, is to the exponent of the power, as the *logarithm* of the root to the *logarithm* of the power.

So that the *logarithm* of the power is had, if the *logarithm* of the root be multiplied by its exponent; and the *logarithm* of the root is had, if the *logarithm* of the power be divided by its exponent.

And hence we derive one of the great uses of *logarithms*, which is to expedite and facilitate the business of multiplication, involution of powers, and extraction of roots; the former of which is here performed by mere addition, and the two latter by multiplication and division.—Thus 3, the sum of the *logarithms* 1 and 2, is the *logarithm* of 8, the product of 2 and 4. In like manner 7, the sum of the *logarithms* 2 and 5, is the *logarithm* of 128, the product of 4 and 32. Again, 6, the *logarithm* of 64, which is the third power of 4 or 4^1, is equal to 3×2. And 8, the *logarithm* of 256, which is the fourth power of 4 or 4^2, is equal to 4×2. Moreover, 3, the *logarithm* of the square root 8, is half the *logarithm* 6, of the square 64; and 2, the *logarithm* of the cube root 4, is subtriple the *logarithm* 6 of the cube 64.

2. *If the* logarithm *of unity be* 0, *the* logarithm *of the quotient will be equal to the difference of the* logarithms *of the divisor and dividend.*—For as the divisor is to the dividend, so is unity to the quotient; therefore the *logarithm* of the quotient is a fourth equidifferent number to the *logarithms* of the divisor, the dividend, and the *logarithm* of unity. The *logarithm* of unity, therefore, being 0, the difference of the *logarithm* of the divisor, and that of the dividend, is the *logarithm* of the quotient. Q. E. D.

Hence appears another great advantage of *logarithms*; viz. their expediting the business of division, and performing it by a bare subtraction. E. gr. 2, the difference between 7 and 5, is the *logarithm* of the quotient 4, obtained by dividing 128 by 32. In like manner, 5, the difference between 8 and 3, is the *logarithm* of the quotient 32, obtained by dividing 256 by 8.

An example or two will render the use of *logarithms* in multiplication, division, &c. obvious.

Num.	Log.	Num.	Log.

log. of sq. R. Cub. 729 3)2.862726(0.954242 *log.* of Cube R.

The properties of *logarithms* hitherto mentioned, and their various uses are taken notice of by Stifelius: but they come all far short of the use of *logarithms* in trigonometry, first discovered by John Napier, baron of Merchiston, in Scotland, and first published at Edinburgh in 1614, in his Mirifici Logarithmorum Canonis Descriptio. This work was translated by Mr. Edward Wright, and published by his son, with the assistance of Mr. Briggs, in the year 1616 or 1618. The method of constructing the table was reserved by the ingenious author, till the sense of the learned upon his invention should be known; nevertheless Kepler, in his Chilias Logarithmorum ad totidem Numeros rotundos, published at Marpurg in 1624; Speidell in his New *Logarithms*, published in 1619, and republished with considerable additions, in a fifth impression in 1624; Bonj. Urfinius, in his Table of *Logarithms*, printed at Cologne, in 1625, and others, at home and abroad, laboured at the computation of *logarithms*, and constructed small tables, conformable to the plan of lord Napier.

To find the logarithm *of any number, and to construct a canon of* logarithms *for natural numbers.*—1. Because, 1. 10. 100. 1000. 10000. &c. constitute a geometrical progression their *logarithms* may be taken at pleasure: to be able, then, to express the *logarithms* of the intermediate numbers by decimal fractions, take 0.00000000, 1.00000000, 2.00000000, 3.00000000, 4.00000000, &c. 2. It is manifest, that for those numbers which are not contained in the scale of geometrical progression, the just *logarithms* cannot be had: yet may they be had so near the truth, that, as to matters of use, they shall be altogether as good as if strictly just. To make this appear, suppose the *logarithm* of the number 9 were required: between 1.0000000 and 10.0000000, find a mean proportional, and between their *logarithms* 0.00000000, and 1.00000000 an equidifferent mean, which will be the *logarithm* thereof; that is, of a number exceeding three by $\frac{1}{1000000}$, and therefore far remote from nine. Between 3 and 10, therefore, find another mean proportional, which may come somewhat nearer 9; and between 10 and this mean another still; and so on between the numbers next above and next underneath 9, till at last you arrive at 9 $\frac{1}{1000000}$; which not being one millionth part from 9, its *logarithm* may, without any sensible error, be taken for that of 9 itself. Seeking then in each case for the *logarithms* of the mean proportionals, you will at last have 0.954251, which is exceedingly near the true *logarithm* of 9. 3. If in like manner you find mean proportionals between 1.0000000 and 3.1622777, and assign convenient *logarithms* to each, you will at length have the *logarithm* of the number 2, and so of the rest. 4. There needs not, however, be so much pains taken in investigating the *logarithms* of all numbers; since those that consist of aliquot parts being divided, and others mutually multiplying each other, their *logarithms* are easily found. Thus if the *logarithm* of the number 9 be bisected, we shall have the *logarithm* 0.477121125 of the number 3.

The indices, or characteristics of *logarithms*, correspond to the denominative part of the natural numbers, as the other member of the *logarithm* does to the numerative part of the number: i. e. the index shews the denomination, or place of the last (or left hand) figure of the number, and consequently of all the rest. Thus 0, affixed to a *logarithm*, denotes the last figure of the number, to which the *logarithm* answers, to be nothing distant from (i. e. in) the place of units. The index 1 shews the last figure of its number to be distant 1 place from the place of units, i. e. to be in the place of tens, and consequently the number itself to be either 10, or some number between that and 100, and so of the other indices. Hence all numbers, which have the same denominative, but not the same numerative part, as all numbers from 1 to 10, from 10 to 100, &c. will have *logarithms*, whose indices are the same, but the other members different. Again, all numbers which have the same numerative, but not

not denominative part, will have different indices; but the reſt of the *logarithms* the ſame. If a number be purely decimal, to its *logarithm* is affixed a negative index, ſhewing the diſtance of its firſt ſignificative figure, from the place of units. Thus the *logarithm* of the decimal .256 is 1.408240, of the decimal, 0256 is 2.408240, &c.

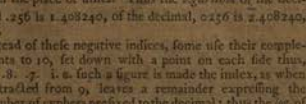
Inſtead of theſe negative indices, ſome uſe their complements to 10, ſet down with a point on each ſide thus, .9. 8. 7. i. e. ſuch a figure is made the index, as when ſubtracted from 9, leaves a remainder expreſſing the number of cyphers prefixed to the decimal: thus the *log.* of

.256 is .9.408240
of .0256, .8. 408240.

Logarithms are not only of great uſe for facilitating computations in arithmetic and trigonometry, but have been found of extenſive ſervice in the higher geometry, particularly in the method of fluxions. The nature and geneſis of *logarithms* are explained above, after the manner made uſe of in moſt elementary treatiſes; but it may be proper to add ſomething more on this ſubject from Mr. Maclaurin's Treatiſe of Fluxions, who has explained the nature and geneſis of *logarithms*, agreeably to the notion of their firſt inventor, Lord Napier, delivered in his Mirif. Logar. Canon. Deſcript.

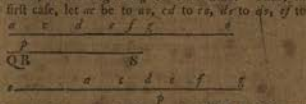
Logarithms, and the quantities to which they correſpond, may be ſuppoſed to be generated by the motion of a point. If this point moves over equal ſpaces in equal times, the line deſcribed by it increaſes equally.

Again, a line decreaſes proportionally, when the point that moves over it deſcribes ſuch parts in equal times as are always in the ſame conſtant ratio to the lines from which they are ſubducted, or to the diſtances of that point at the beginning of thoſe times, from a given term in the line. In like manner, a line may increaſe proportionally, if in equal times the moving point deſcribes ſpaces proportional to its diſtances from a certain term, at the beginning of each time. Thus, in the firſt caſe, let *ac* be to *ae*, *cd* to *eb*, *df* to *ec*, *ef* to



eo, *fg* to *fo*, always in the ſame ratio of QR to QS; and ſuppoſe that the point *p* ſets out from *a*, deſcribing *ac*, *cd*, *de*, *ef*, *fg*, in equal parts of the time; and let the ſpace deſcribed by *p*, in any given time, be always in the ſame ratio to the diſtance of *p* from *e*, at the beginning of that time, then will the right line *ae* decreaſe proportionally; and the lines *ae*, *ce*, *de*, *ee*, *fe*, &c. of the diſtances of the point *p* from *e*, at equal ſucceeding intervals of time, are in a continued geometrical progreſſion.

In like manner the line *ae* increaſes proportionally, if the point *p* in equal times deſcribes ſpaces *ac*, *cd*, *de*, *ef*, *fg*, &c. ſo that *ac* is to *ae*, *cd* to *ce*, *de* to *de*, &c. in a conſtant ratio.



If we now ſuppoſe a point P deſcribing the line AB with an uniform motion; equal to that with which *p* ſets out from *a*, in deſcribing the line *ae*, while the point *p* deſcribes a line increaſing or decreaſing proportionally, the line AP deſcribed by P with this uniform motion, in the ſame time that *ae*, by increaſing or decreaſing proportionally, becomes equal to *ep*, is the *logarithm* of *ep*. Thus AC, AD, AE, &c. are the *logarithms* of *ac*, *ad*, *ae*, &c. reſpectively; and *aa* is the quantity whoſe *logarithm* is ſuppoſed equal to nothing.

We have here abſtracted from numbers, that the doctrine may be the more general; but it is plain, that if AC, AD, AE, &c. be ſuppoſed 1, 2, 3, &c. in arithmetic progreſſion; *ac*, *ad*, *ae*, &c. will be in geometric progreſſion; and that the *logarithm* of *ae*, which may be taken for unity, is nothing.

Lord Napier, in his firſt ſcheme of *logarithms*, ſuppoſes, that while *ep* increaſes or decreaſes proportionally, the uniform motion of the point P, by which the *logarithm* of *ep* is generated, is equal to the velocity of *p* at *q*; that is, at the term of time when the *logarithms* begin to be generated. Hence *logarithms*, formed after this model, are called *Napier's logarithms*, and ſometimes *natural logarithms*.

When a ratio is given, the point *p* deſcribes the difference of the terms of the ratio in the ſame time. When a ratio is duplicate of another ratio, the point *p* deſcribes the difference of the terms in a double time. When a ratio is triplicate of another, it deſcribes the difference of the terms in a triple time; and ſo on. Alſo when a ratio is compounded of two or more ratios, the point *p* deſcribes the difference of the terms of that ratio, in a time equal to the ſum of the times in which it deſcribes the differences of the terms of the ſimple ratios of which it is compounded. And what is here ſaid of the times of the motion of *p*, when *ep* increaſes proportionally, is to be applied to the ſpaces deſcribed by P in thoſe times, with its uniform motion.

Hence the chief properties of *logarithms* are deduced. They are the meaſures of ratios. The exceſs of the *logarithm* of the antecedent above the *logarithm* of the conſequent meaſures the ratio of thoſe terms. The meaſure of the ratio of a greater quantity to a leſſer is poſitive, as this ratio compounded with any other ratio increaſes it. The ratio of equality, compounded with any other ratio, neither increaſes nor diminiſhes it; and its meaſure is nothing. The meaſure of the ratio of a leſſer quantity to a greater is negative, as this ratio compounded with any other ratio diminiſhes it. The ratio of any quantity A to unity, compounded with the ratio of unity to A, produces the ratio of A to A, or the ratio of equality; and the meaſures of thoſe two ratios deſtroy each other, when added together; ſo that when the one is conſidered as poſitive, the other is to be conſidered as negative.

When *ep* increaſes proportionally, the motion of *p* is perpetually accelerated; and, on the contrary, when *ep* decreaſes proportionally, the motion of *p* is perpetually retarded.

If the velocity of the point *p* be always as the diſtance *ep*, then will this line increaſe or decreaſe in the manner ſuppoſed by Lord Napier; and the velocity of the point *p* being the fluxion of the line *ep*, will always vary in the ſame ratio as this quantity itſelf. See Maclaurin's Flux. art. 161—166.

The fluxion of any quantity is to the fluxion of its *logarithm*, as the quantity itſelf is to unity.

Hence the FLUXION of the *logarithm* of x will be $\frac{\dot{x}}{x}$.

For $x : 1 :: \dot{x} : \frac{\dot{x}}{x}$ = the fluxion of the *logarithm* required.

When *ep* increaſes proportionally, the ſpaces generated in any equal times, are accurately in the ſame ratio as the velocities of *p*, or the fluxions of *ep*, at the beginning, end, or at any ſimilar terms of thoſe times.

When *ep* increaſes or decreaſes proportionally, the fluxions of this line, of all the higher orders, increaſe or decreaſe in the ſame proportion as the line itſelf increaſes or decreaſes; ſo that one rule ſerves for comparing together thoſe of any kind at different terms of time: and in this caſe we never arrive at any conſtant or invariable fluxion.

If the *logarithms* of two quantities be always to each other in any invariable ratio, the fluxions of thoſe quantities ſhall be in a ratio that is compounded of the ratio of the quantities themſelves, and of the invariable ratio of their *logarithms*.

Let *op* be greater than *oa*: *od*: *op* : *oa* : *op*; and let *ao*, *p q a d e f g h k p o*

aq, *de*, *ef*, *fg*, &c. be in continued proportion: then by adding together $\frac{1}{2}aq$, $\frac{1}{2}de$, $\frac{1}{2}ef$, $\frac{1}{2}fg$, &c. we approximate continually to the value of AP, the *logarithm* of *op*. And we approximate continually to the *logarithm* of *od*, by ſumming up the differences betwixt $\frac{1}{2}aq$ and $\frac{1}{2}de$, $\frac{1}{2}ef$ and $\frac{1}{2}fg$, $\frac{1}{2}gh$ and $\frac{1}{2}hk$, &c.

Theſe theorems are demonſtrated geometrically by Mr. Maclaurin, lib. cit. art. 171, 172. From what has been ſaid, it follows, that if *oa* : *od* :: *op* : *oe*, then the *logarithm* of *oe* will be equal to the ſum of the *logarithms* of *op* and *od*; that is, to the ſum of $\frac{1}{2}qd + \frac{1}{2}de + \frac{1}{2}ef + \frac{1}{2}fg + \frac{1}{2}gh + \frac{1}{2}hk$, &c. and $aq - \frac{1}{2}de + \frac{1}{2}ef - \frac{1}{2}fg + \frac{1}{2}gh - \frac{1}{2}hk$, &c. which ſum is $2aq + \frac{1}{3}ef + \frac{1}{5}gh$, &c.

Let $aq = ad$; then the *logarithm* of *oe* will meaſure the ratio of *od* to *oq*. But *ad* and *aq* have half their ſum equal to *ao*, and half their difference equal to *ad*, which are the two firſt terms of the geometric progreſſion *ao*, *ad*, *de*, *ef*, *fg*, *gh*, *hk*, &c. Hence, if $ao = 1$, and $ad = x$, de, ef, fg, &c. will be reſpectively, x^2, x^3, x^4, &c. and the ratio of $1 + x$ to $1 - x$ will be equal to that of *od* to *op*. But the *logarithm* of this ratio is $2ad + \frac{2}{3}ef + \frac{2}{5}gh +$, &c. therefore the *logarithm* of $\frac{1+x}{1-x} = 2 \times x + \frac{2}{3}x^3 + \frac{2}{5}x^5 + \frac{2}{7}x^7 +$, &c. agreeably to what has been ſhewn by Dr. Halley and others.

This ſeries is analytically deduced from the nature of *logarithms*, by Mr. Simſon in his Trigonometry, p. 40, &c.

The hyperbolic *logarithm* of any number is the index of that term of the logarithmic progreſſion, agreeing with the propoſed number, multiplied by the exceſs of the

common

common ratio above unity: thus if e be an indefinite small quantity, the hyperbolic *logarithm* of the natural number agreeing with any term $1+e^n$ of the logarithmic progreſſion 1, $1+e$, $1+e^2$, $1+e^3$ &c. will be expreſſed by ne. And ſince $1+e)^n=N$ or the number, we ſhall have $1+e=N^{\frac{1}{n}}=1+x)^m$, by putting $1+x=N$, and $m=\frac{1}{n}$. Therefore $\overline{1+x}^m$ being $=1+mx+m\times\frac{m-1}{2}\times x^2+m\times\frac{m-1}{2}\times\frac{m-2}{3}\times x^3$, &c. we have $e=mx+m\times\frac{m-1}{2}\times x^2$, &c. where m being rejected in the factors $m-1$, $m-2$, &c. as indefinitely ſmall in compariſon of 1, 2, &c. becauſe n is, from the nature of *logarithms*, indefinitely great, the equation will become $e=mx-\frac{mx^2}{2}+\frac{mx^3}{3}-\frac{mx^4}{4}$, &c. whence $\frac{e}{m}\,(=ne=\mathrm{L})=x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}$, &c. But this ſeries, though the moſt eaſy and natural, is of little uſe in determining the *logarithms* of large numbers, becauſe, in all ſuch caſes, it diverges, inſtead of converging.

In order to obtain a ſeries that will always converge, let the number, whoſe *logarithm* is wanted, be denoted by $\frac{1}{1-x}$, in which quantity will be always leſs than unity, and let $1+e^n$ as before be $=\frac{1}{1-x}$; then $1+e=\frac{1}{1-x})^{\frac{1}{n}}=\overline{1-x}^{-\frac{1}{n}}=\overline{1-x}^m$ (by making $m=-\frac{1}{n}$) $=1-mx+m\times\frac{m-1}{2}\times x^2-m\times\frac{m-1}{2}\times\frac{m-2}{3}\times x^3$, where m being rejected in the factors $m-1$, $m-2$, &c. as before, the equation will become $1+e=1-mx+\frac{mx^2}{2}-\frac{mx^3}{3}$, &c. whence $x+\frac{x^2}{2}+\frac{x^3}{3}$, &c. $=\frac{e}{-m}=ne=$ the hyperbolic *logarithm* of $\frac{1}{1-x}$; which ſeries will always converge, let the value of $\frac{1}{1-x}$ be ever ſo great, becauſe x will be always leſs than unity. But this ſeries being added to the former, expreſſing the *logarithm* of $1+x$, the ſeries $2x+\frac{2x^3}{3}+\frac{2x^5}{5}+\frac{2x^7}{7}$, &c. thence ariſing will be more ſimple than either of them, ſince one half of the terms will be entirely deſtroyed thereby: conſequently, as the ſum of the *logarithms* of any two numbers is equal to the *logarithm* of the product of thoſe numbers, the ſeries $2x+\frac{2x^3}{3}+\frac{2x^5}{5}$, &c. will truly expreſs the *logarithm* of $\frac{1+x}{1-x}$, or $\frac{1}{1-x}\times 1+x$. In order to find the value of x, let $\frac{1+x}{1-x}=N$, and x will be $=\frac{N-1}{N+1}$; but if the quantity propoſed be a fraction $=\frac{P}{Q}$, make $\frac{P}{Q}=\frac{1+x}{1-x}$, and x will be $=\frac{P-Q}{P+Q}$; either of which values ſubſtituted in the foregoing ſeries $2x+\frac{2x^3}{3}$, &c. will give the hyperbolic *logarithm* of the reſpective number.

To find, for example, the *logarithm* of 2, from this expreſſion of the *logarithm* of $\frac{1+x}{1-x}$. Then $\frac{1+x}{1-x}=2$, or $1+x=2-2x$, and $3x=1$, or $x=\frac{1}{3}$; that is in decimals:

x	$(=\frac{1}{3})$	$=0.333333333$, &c.
x^3	$(=\frac{1}{27})$	$=.037037037$, &c.
x^5	$(=\frac{1}{243})$	$=.004115226$, &c.
x^7	$(=\frac{1}{2187})$	$=.000457247$, &c.
x^9	$(=\frac{1}{19683})$	$=.000050805$, &c.
x^{11}	$(=\frac{1}{177147})$	$=.000005645$, &c.
x^{13}	$(=\frac{1}{1594323})$	$=.000000627$, &c.
x^{15}	$(=\frac{1}{14348907})$	$=.000000069$, &c.

Theſe values being reſpectively divided by the numbers 1, 3, 5, 7, 9, &c. and the ſeveral quotients added together, we ſhall have .346573590, &c. whoſe double, being .693147180, &c. is the hyperbolical or Napier's *logarithm* of the number 2. In the ſame manner the hyperbolic *logarithms* of any other numbers may be determined; but the moſt ready way of deriving *logarithms* from others already known is the following: let a, b, c, denote any three numbers in arithmetical progreſſion, whoſe common difference is unity; then, a being $=b-1$, and $c=b+1$, we ſhall have $ac=b^2-1$, and $\frac{b^2}{ac}=\frac{ac+1}{ac}$: whence, by the nature of *logarithms*, we ſhall have $2\ log.\ b-log.\ a-log.\ c=log.\ \frac{ac+1}{ac}$; but the *logarithm* of $\frac{ac+1}{ac}$ putting $\frac{1}{2ac+1}=x$, ſince $\frac{P}{Q}=\frac{ac+1}{ac}=\frac{1+x}{1-x}$, and $x=\frac{P-Q}{P+Q}=\frac{1}{2ac+1}$, will be $\frac{2x}{1}+\frac{2x^3}{3}+\frac{2x^5}{5}+\frac{2x^7}{7}$, &c. which being denoted by S, we ſhall have $\left\{\begin{array}{l} log.\ b=\frac{1}{2}\,log.\ a+\frac{1}{2}\,log.\ c+\frac{1}{2}\,S. \\ log.\ a=2\,log.\ b-log.\ c-S. \\ log.\ c=2\,log.\ b-log.\ a-S. \end{array}\right\}$

E. g. To find the hyperbolic *logarithm* of 3.

The *logarithm* of 2 being known, that of 4, which is the double of the former will alſo be known. Therefore, taking $a=2$, $b=3$, and $c=4$, we ſhall have $x\left(=\frac{1}{2ac+1}\right)=\frac{1}{17}$; and $x^2=\frac{1}{289}$. Whence,

$x\left(=\frac{1}{17}\right)=.058823529$, &c.

$x^3\left(=\frac{x}{289}\right)=.000203542$, &c.

$x^5\left(=\frac{x^3}{289}\right)=.000000704$, &c. Therefore, $\frac{1}{2}S\left(x+\frac{x^3}{3}+\frac{x^5}{5},\text{ &c.}\right)=.058891517$, &c. and conſequently the hyperbolic *log.* of $3\left(\frac{hyp.\ log.\ 2+hyp.\ log.\ 4}{2}+\frac{1}{2}S\right)=1.098612288$, &c.

If the hyperbolic *logarithm* of 10 were required; the *logarithms* of 8 and 9 being given from thoſe of 2 and 3 already found, a may be $=8$, $b=9$, and $c=10$; then $x\left(\frac{1}{2ac+1}\right.$ being $\left.=\frac{1}{161}\right)$, we ſhall have $\frac{1}{2}S\left(x+\frac{x^3}{3}+\frac{x^5}{5},\text{ &c.}\right)=.006211180$, &c. $+.000000079$, &c. &c. $=.006211259$, &c. and, therefore, the *logarithm* of 10 $(2\ log.\ 9-log.\ 8-S)=2.302585092$, &c.

Logarithms of any other kind may be derived from theſe by multiplying by the proper multiplicator or modulus. Thus to convert any of Napier's, or of the natural *logarithms* into Brigg's, or thoſe of the common form, where the *logarithm* of 10 is unity, ſince the *logarithms* of all forms preſerve the ſame proportion with reſpect to each other, ſay, as Napier's *logarithm* of 10 is to 1, ſo is any other of Napier's *logarithms* to Brigg's *logarithm* of the ſame number. Hence, Brigg's *logarithm* will be equal to Napier's divided by 2.302585092, &c. or, which comes to the ſame thing multiplied by its reciprocal $\frac{1}{2.302585092}$ or 0.434294481, &c. And *vice verſa*, Brigg's *logarithms* being given, to find Napier's correſponding, multiply Brigg's by 2.302585092, &c.

In general, to find Brigg's *logarithm* of any number n. Let $\frac{1+x}{1-x}=n$, and conſequently $x=\frac{n-1}{n+1}$. Multiply x by 0.868588096, &c. $(=2\times 0.434294481$, &c.) and then continually multiply this product by xx, and divide the reſulting products, reſpectively, by the terms of the progreſſion 1, 3, 5, 7, &c. The ſum of theſe quotients will be Brigg's *logarithm* required.

Thus, $2x+\frac{2x^3}{3}+\frac{2x^5}{5}$, &c. $\times\ 0.434294481$, &c. expreſſing the common *logarithm* of $\frac{1+x}{1-x}$, this ſeries, by making $R=.868588963$, &c. will be $Rx+\frac{Rx^3}{3}+\frac{Rx^5}{5}+\frac{Rx^7}{7}$, &c. Therefore, to find the *logarithm* of 7, thoſe of 8 and 9 being known, we ſhall have $log.\ 7=2\ log.\ 8-log.\ 9-S$; and $S=Rx+\frac{Rx^3}{3}+\frac{Rx^5}{5}$, &c. $=$ the common *logarithm* of $\frac{64}{63}$. $\frac{ac+1}{ac}$ being $=\frac{64}{63}$; and $x=\frac{64-63}{64+63}=\frac{1}{127}$; whence $\left(x^2\text{ being}=\frac{1}{16129}\right)$ we ſhall have,

$Rx\left(=\frac{868\text{ &c.}}{127}\right)=.006839283$, &c.

$Rx^3\left(=\frac{Rx}{16129}\right)=.000000424$, &c.

Rx^5

$R+\left(=\frac{R^3}{10.179}\right)=.0000000002$, &c. Consequently S $\left(R+\frac{R^3}{3}+\frac{R^5}{5}, \text{ &c.}\right)=.0006839474$, &c. and 2 *log.* 8 $-$ *log.* 9 $-$ S $=.8450980400$, &c. $=$ the common *logarithm* of 7 required. But this may be obtained by fewer terms of the series from the *logarithms* of the 3 firſt primes 2, 3, and 5; becauſe theſe of 48 and 50, compoſed of them, will alſo be known: therefore the *logarithm* of 7 $\left(=\frac{1}{4}\text{log. } 49=\frac{\text{log. } 48+\text{log. } 50+S}{4}\right)$ will be $=.8450980400$, &c. as before, true from the firſt term of the ſeries only, to 11 places of figures.

Thus alſo the *logarithm* of the next prime number 11 may be obtained: by making $a=10$. $b=11$, and $c=11$; or by making $a=98$, or $2\times7\times7$ $b=99$ or $3\times3\times11$, and $c=100$ or $2\times2\times5\times5$; and then, by the firſt term of the ſeries, the *logarithm* of 99 will be found true to 14 places; whence that of 11 (*log.* 99 $-$ *log.* 9) is alſo known. Simpſon ubi ſupra. Cotes's Harm. Menſ. prop. I and II. Saunderſon's Algebra, vol. ii. part 2. p. 616.

As to the various compendia ariſing in the practice of conſtructing a table of *logarithms*, we refer to Gardiner's, and to Sherwin's Tables.

We have already obſerved, that Napier's, or the natural *logarithm* of any quantity, is found by ſuppoſing the uniform motion of the point P, by which the *logarithm* of op is generated, to be equal to the velocity of p, at the term of time when the *logarithms* begin to be generated.

But the uniform motion of P may be ſuppoſed equal to the motion of p at any other term, as when it comes to s; in which caſe, the conſtant velocity of P is to the velocity with which p ſets out from a, when the *logarithm* begins to be generated, as sv is to sa. Thus, we may have as many *logarithms* as we pleaſe; and the line se is what Mr. Cotes calls the *modulus of the ſyſtem*.

The meaſures of a given ratio in the different ſyſtems are in the ſame proportion as the lines se, e being always the term where the velocity of p becomes equal to the conſtant velocity of P. Hence, the *logarithm* of any quantity in Napier's firſt ſyſtem becomes equal to the *logarithm* of the ſame quantity in any other ſyſtem, whoſe modulus is se, by multiplying by the number which expreſſes the ratio of se to sa; and the modulus of any ſyſtem is to the modulus of any other ſyſtem, as the *logarithm* of any given quantity in the firſt is to its *logarithm* in the ſecond. Thus in Napier's firſt ſcheme, in the ſame time that op, from being equal to sa, becomes equal to ten times sa, the point P deſcribes a line, the ratio of which to sa is that of 2.30258509, &c. to unity. But it was found convenient, that the *logarithm* of 10 ſhould be 1; and the motion of P was ſuppoſed to be ſo far diminiſhed, that the ſpace deſcribed by it in that time might be equal only to sa; that is, its velocity, in this caſe, was ſuppoſed leſs than its velocity in the former, in the ſame ratio, as 1 is leſs than 2.30258, &c. If se be taken leſs than sa in the ſame ratio, the velocity of P ſhall be equal, in this caſe, to the velocity of p at e; and se will be the modulus of this ſyſtem, which will therefore be expreſſed by $\frac{1}{2.30258509, \text{ &c.}}=.43429448$, &c. $=\frac{1}{sa}$, sa being unity. Maclaurin, lib. cit. art. 174.

When a ratio is given, its meaſure is always as the modulus of the ſyſtem. It is therefore the ſame invariable ratio that is always meaſured by the modulus of the ſyſtem, which is called by Mr. Cotes *ratio modularis*. This ratio is that of sm to se, if op by increaſing proportionally, from being

equal to se, becomes equal to sm, in the ſame time that P, by its uniform motion, deſcribes a line equal to the modulus se. Ibid. art. 175, 753.

This *ratio modularis* is found to be that of 2.71828182845, &c. to 1; or of 1 to 0.36787944117, &c. Cotes, Harm. Menſur. p. 7.

If a *logarithm* x be given, the number correſponding, if x be a natural *logarithm*, will be expreſſed by this ſeries, $1+x+\frac{1}{2}x^2+\frac{1}{6}x^3+\frac{1}{24}x^4+\frac{1}{120}x^5+\frac{1}{720}x^6+$, &c. or generally, if the modulus be M, by this, $1+\frac{x}{M}+\frac{x^2}{2M^2}+\frac{x^3}{6M^3}+$, &c. which when $x=M$ is changed into $1+1+\frac{1}{2}+\frac{1}{6}+\frac{1}{24}+\frac{1}{120}+$, &c. or $1+\frac{1}{1}+\frac{1}{1.2}+\frac{1}{1.2.3}+\frac{1}{1.2.3.4}+\frac{1}{1.2.3.4.5}+\frac{1}{1.2.3.4.5.6}+$, &c. $=2.7182818$, &c. the ratio of which to 1 is the ratio modularis. See Maclaurin, Flux. art. 753. Cotes, Harm. Menſ. p. 6, 7.

We have ſaid, that in Lord Napier's firſt ſyſtem, the conſtant velocity of P, by which the *logarithm* AP is generated, is equal to the velocity with which p ſets out from a. Therefore, if we ſuppoſe AP and ap to be diminiſhed continually,

AP being always the *logarithm* of op, their ratio ſhall continually approach to a ratio of equality as its LIMIT. And, an being ſuppoſed to repreſent unity, if op be very ſmall compared with an, it may be ſuppoſed in approximations to be the *logarithm* of on, in this ſyſtem; and any very ſmall fraction may be ſuppoſed to be the *logarithm* of the ſum of unity and that fraction added together. From this it follows, that if a ſeries of mean proportionals be interpoſed between sa and any given line ab, and the number of all the terms, excluſive of sa, be x; and sn being the ſecond term of the ſerics, an be to ab as unity is to the number q: then, by increaſing continually the number of mean proportionals betwixt sa and ab, the ratio of x to q ſhall approach continually to the ratio of AB (the *logarithm* of ob) to ab, as its limit. For the number x is to unity as AB is to AN (the *logarithm* of on); and unity is to q as an (which approaches continually to AN) is to ab. Therefore the ratio of x to q approaches continually to that of AB to ab. For inſtance, if ab be double of sa, the ratio of x to q approaches continually to the ratio of the natural *logarithm* of 2 to unity, which is nearly that of 7 to 10. Maclaurin lib. cit. art. 179. and De Moivre Doctr. of Chances, probl. 5.

The firſt canon of *logarithms* for natural numbers, from 1 to 20000, and from 90000 to 101000, was conſtructed by Hen. Briggs, with the approbation of the inventor, the lord Napier, and in purſuance of a hint ſuggeſted by him in 1616, who propoſed altering his firſt canon, by making 0 the *logarithm* of unity, and 10 that of the fine total, and the manner of conſtructing them ſhewn in his Arithmetica *Logarithmica*, publiſhed in 1624. Of this method Dr. Halley ſays, that to have his *logarithms* true to 14 places of figures, Mr. Briggs, by continual extraction, was obliged to find the root of more than the 140 million of millionth power. Briggs lived to complete a table of logarithmic fines and tangents, to the 100th part of every degree, and to 14 places of figures, beſides the index; to which he intended to have added a full deſcription and uſe: but, being prevented by death, this was done by Mr. Henry Gellibrand, in his Trigonometria Britannica, publiſhed at London, or as ſome ſay, at Gouda, in 1633. The chaſm between 20000 and 90000, was filled up by Adrian Ulacq, who publiſhed a ſecond edition of the Arithmetica *Logarithmica*, at Tergou, in 1628, in which was contained all the *logarithms* from 1 to 100000 to 10 places of figures, together with a table of artificial fines, tangents, and ſecants, to every minute of the quadrant. Some copies of Ulacq's tables were purchaſed by our bookſellers, and publiſhed at London, with an Engliſh explanation premiſed, dated 1631. Ulacq alſo publiſhed at the ſame place, in 1633, his Trigonometria Artificialis, with tables of logarithmic fines and tangents to every tenth ſecond of the quadrant. Ulacq's tables are in high eſteem for their exactneſs, as are alſo amongſt us Sherwin's firſt edition, in 1706, in which we have the *logarithms* of numbers from 1 to 101000, together with the differences and proportional parts, whereby the *logarithm* of any number under 10.000.000 may eaſily be found; and Gardiner's in 1742, containing the *logarithms* for all numbers from 1 to 102100, with the differences and proportional parts. M. de Fontenelle, in the Hiſtory of the Academy of Sciences, for 1717, commends an edition of Ulacq's ſmaller tables, made at Lyons, in 1670. and M. de la Lande, in his Aſtronomy, printed at Paris in 1764. tables publiſhed there in 1760.

In the common tables we have only a canon from 1 to 10000.—There are various other methods of conſtructing *logarithms*, by Dr. Halley, Mercator, Mr. Cotes, Dr. Brook Taylor, &c. which the reader may find in the Philoſophical Tranſactions, and other treatiſes on this ſubject.

As we have frequent occaſion for recurring to tables of *logarithms*, in the courſe of this work, we ſhall here, with a view of rendering the work more complete, annex thoſe in common uſe.

A Table of Logarithms, from 1 to 10000.

Use of the preceding table.

To find the logarithm *of any number within the compass of the table.*—If the number be under 100, it is eafily found in the firſt diviſion at the head of the firſt page; if it be betwixt 100 and 1000, over againſt the number in the firſt column of the following pages, in the next column under 0 will be found the *logarithm* required. If the number be betwixt 1000 and 10000, the firſt three figures of the number are to be found in the column marked N° and the fourth figure at the top, and in the column under it, lineally againſt the firſt three figures, will be found the *logarithm* required, changing the index 2 into 3. The column, marked Diff. and ſhewing the common difference by which each of thoſe columns increaſes, ſerves to find the *logarithms* of numbers beyond 10000. Thus,

To find the logarithm *for a number greater than any in the common canon, but leſs than* 100000.—Cut off four figures on the left of the given number, and ſeek the *logarithm* in the table; add as many units to the index, as there are figures remaining on the right; ſubtract the *logarithm* found from the next following it, in the table; then, as the difference of numbers in the canon is to the tabular diſtance of the *logarithms* anſwering to them, ſo are the remaining figures of the given number to the logarithmic difference; which, if it be added to the *logarithm* before found, the ſum will be the *logarithm* required. Suppoſe v. g. the *logarithm* of the number 93275 required. Cut off the four figures 9327, and to the characteriſtic of the *logarithm* correſponding to them, add an unit; then,

From the *logarith.* of the numb. 9328	=3.965578
Subtract *logarith.* numb. 9327	=3.965531
Remains tabular difference	47

Then 100 : 47 :: 5 : 23

Now to the *logarithm*	4.965531
Add the difference found	23
The ſum is the *logarithm* required	4.965554

Or more briefly; find the *logarithm* of the firſt four figures as before; then multiply the common difference which ſtands againſt it by the remaining figures of the given number; from the product, cut off as many figures at the right hand as you multiplied by, and add the remainder to the *logarithm* before found, fitting it with a proper index. Thus $47 \times 5 = 235$; cut off 5 and add 23.

To find the logarithm *of a fraction.*—Subtract the *logarithm* of the numerator from that of the denominator, and to the remainder prefix the ſign of negation. Thus ſuppoſe it required to find the *logarithm* of the fraction $\frac{3}{7}$,

Logarithm of 7 =	0.845098
Logarithm of 3 =	0.477121
Logarithm of $\frac{3}{7}$ =	0.367977

The reaſon of the rule is, that a fraction being the quotient of the numerator divided by the denominator, its *logarithm* muſt be the difference of the *logarithms* of thoſe two; ſo that the numerator being ſubtracted from the denominator, the difference becomes negative. Obſerve, that the *logarithms* of a proper fraction muſt always be negative, if that of unity be 0; which is evident, a fraction being leſs than one.

Or, the *logarithm* of the denominator, though greater than that of the numerator, as in the caſe of a proper fraction, may be ſubtracted from it, regard being had to the ſign of the index, which alone in that caſe is negative. Thus,

Log. of 3 =	0.477121
Log. of 7 =	0.845098
Log. of $\frac{3}{7}$ =	1.632023 which produces the

ſame

same effect in any operation, as that before found, viz. —0.387077, this being to be subtracted, and the other to be added.

Or again, the fraction may be reduced to a decimal, and its *logarithm* found; which differs from that of a whole number only in the index, which is to be negative.

For an improper fraction v. gr. $\frac{7}{5}$, its numerator being greater than its denominator, its *logarithm* is had, by subtracting the *logarithm* of the latter from that of the former.

The *logarithm* of 7 = 0.8450980
Logarithm of 5 = 0.6989700
Logarithm $\frac{7}{5}$ = 0.1561280

In the same manner may a *logarithm* of a mixt number, as $7\frac{3}{5}$, be found, it being first reduced into an improper fraction $\frac{38}{5}$.

Or, this improper fraction may be reduced to a mixed number, whose *logarithm* must be found as if it were wholly integral, and its index taken according to the integral part. We shall here observe, that the *logarithms* of whole numbers are added, subtracted, &c. according to the rules of those operations in decimal arithmetic; but with regard to the management of *logarithms* with negative indices, the same rules are to be observed as those given in Algebra for like and unlike signs.

In addition, all the figures, except the index, are reckoned positive, and, therefore the figure to be carried to the index from the other part of the *logarithm*, takes away so much from the negative index. Thus 1.8823526 + 3.699972 = 1.582238. In subtraction, if either one or both of the *logarithms* have negative indices, you muſt change the ſign of the index of the ſubtrahend, after you have carried to it what may ariſe from the decimal part, and then add the indices: thus 1.582208 − 1.883326 = 3.699972. In multiplication, what is carried from the product of the other parts of the *logarithms* muſt be ſubtracted from the product of the indices: thus 2.477121 × 5 = 8.385605. In diviſion, if the diviſor will exactly meaſure the index, proceed as in common arithmetic: e. g. 3.924384 ÷ 2 = 2.462192. But if the diviſor will not exactly meaſure the index, add units to the index, till you can exactly divide it, and carry thoſe units to the next number: e. g. 8.385605 ÷ 5 = 2.477121.

To find the number corresponding to any given logarithm. If the *logarithm* be within the limits of the table, i. e. if its index does not exceed 3, then, neglecting the index, look down in the column of *logarithms* under 0, for the two or three firſt figures of your given *logarithm*, and if you exactly find all the figures of the given *logarithm* in that column, you have the number corresponding at the left hand. But if you do not find your *logarithm* exactly in the column under 0, you muſt run through the other columns, till you find it exactly, or till you obtain the next leaſt *logarithm*; and in the column of numbers baſically againſt it, you have the firſt 3 figures of the number ſought, to which join the figure over the column, where your *logarithm* or its next leaſt was found, and you have the correſponding number. E. g. The number anſwering to the *logarithm* 3.544812 is 3560.

If the index of this *logarithm* had been 1, then the two laſt figures of the number would have been decimal; with the index 0, its correſponding number would have been 3.560; with 2, 356.0; with 3, 3560, &c.

If the *logarithm* cannot be found exactly, take the next leaſt, and make the difference between the given *logarithm* and the next leaſt the numerator of a fraction, whoſe denominator ſhall be the common difference, and add the fraction to the number found in the table.

To find the number corresponding to a logarithm *greater than any in the table.*—Firſt, from the given *logarithm*, ſubtract the *logarithm* of 10, or 100, or 1000, or 10000, till you have a *logarithm* that will come within the compaſs of the table; find the number correſponding to this, and multiply it by 10, or 100, or 1000, or 10000, the product is the number required.

Suppoſe, for inſtance, the number correſponding to the *logarithm* 7.758981 be required: ſubtract the *logarithm* of the number 10000, which is 4.0000000, from 7.758981; the remainder is 3.758981; the number correſponding to which is 5741.11: this multiplied by 10000, the product is 57411100, the number required.

Otherwiſe look the decimal number of the *logarithm* in the table, and if you can find it exactly, you have the four firſt figures of the number in the table, to which affix as many cyphers as the given index exceeds 3, and it is the number required. But if you cannot find the *logarithm* exactly, take the next leaſt, and find the four firſt figures of the correſponding number; then take the difference between the given *logarithm* and the next leaſt, and annex to it as many cyphers as the index exceeds 3; then divide by the common difference, and affix the quotient to the 4 firſt figures, and you have the number required.

To find the number corresponding to a negative logarithm.—To the given negative *logarithm*, add the laſt *logarithm* of the table, or that of the number 10000; i. e. ſubtract the firſt from the ſecond, and find the number correſponding to the remainder: this will be the numerator of the fraction, whoſe denominator will be 10000; v. gr. ſuppoſe it to be required to find the fraction correſponding to the negative *logarithm* ——————0.367977, ſubtract this from
4.0000000

The remainder is ——— 3.632023, the number correſponding to which is 4285/10000, the fraction ſought therefore is $\frac{4285}{10000}$.—The reaſon of the rule is, that as a fraction is the quotient, ariſing on the diviſion of the numerator by the denominator, unity will be in the fraction, as the denominator to the numerator; but as unity is to the fraction correſponding to the given negative *logarithm*, ſo is 10000 to the number correſponding to the remainder: therefore, if 10000 be taken for the denominator, the number will be the numerator of the fraction required.

The negative *logarithm* —0.367977 is equal to the *logarithm* 1.632023, and the number anſwering to it, found in the manner already directed, will be .4285/10000.

To find a fourth proportional to three given numbers.—Add the *logarithm* of the ſecond to that of the third, and from the ſum ſubtract the *logarithm* of the firſt; the remainder is the *logarithm* of the fourth required. E. gr. let the given numbers be 4, 68, and 3.

Logarithm 68 = 1.832509
Logarithm 3 = 0.477121
Sum = 2.309630
Logarithm 4 = 0.602060
Logarithm required 1.707570

The number to the tables correſponding to which is 51.—Otherwiſe, againſt the firſt term, write the ARITHMETICAL *complement* of its *logarithm*, and againſt the ſecond and third terms write their *logarithms*; and the ſum of theſe three *logarithms*, abating 10 in the index, will be the *logarithm* of the fourth term. Thus

4 — 9.397940
68 — 1.832509
3 — 0.477121
51 — 1.707570 as before.

This problem is of the utmoſt uſe in trigonometry. See TRIANGLE and TRIGONOMETRY.

For the method of performing multiplication, diviſion, involution, and extraction of roots by *logarithms*, ſee the beginning of this article.

In the common tables of *logarithms* we find the *logarithm* correſponding to any given number within the limits of the table by inſpection; but it is of uſe alſo to have a table wherein the *logarithms* are placed in their natural order from 0 to 100000 for inſtance, and with the correſponding natural numbers; ſo that a *logarithm* being given, we may find the correſponding number by inſpection only, which can ſeldom be done by the common tables; nor can the correſponding number to a *logarithm* not in the table be found without ſome trouble.

A table of this ſort is called by Dr. Wallis an *anti-logarithmic canon*; and by this canon a *logarithm* being given, its number may be found with the ſame facility that a *logarithm* of a given number may be found by the common canon.

Dr. Wallis tells us, that a canon of this kind was formed many years ago. It was begun, perhaps, by Harriot, and it was diſtributed at leaſt, and prepared for the preſs, if not begun by Warner. This canon ſeems to have been loſt; but the loſs has been ſupplied by Mr. Dodſon. See the *Anti-logarithmic canon* by James Dodſon, Lond. 1742. fol. where the author alſo ſhews the conſtruction and uſe of his table at large; and in which he has computed the numbers correſponding to every *logarithm* from 1 to 100000, to 11 places of figures.

LOGARITHMIC, *hyperbola*, are the ſame as natural *logarithms*, or thoſe of Napier's firſt ſcheme.

The reaſon of the appellation is the analogy *hyperbolic* ſpaces have to *logarithms*. Thus,

It is known, that if on the aſymptote OS of an hyperbola LMN, Tab. II. *Analyſis*, fig. 49. the abſciſſæ OA, OP, OG, OR, &c. be taken in geometric progreſſion, the correſponding ſectors LOM, LON, LOQ, &c. or the ſegments LAPM, LAGN, LARQ, &c. will be in arithmetical progreſſion. Hence, the ſegments or ſectors will be the *logarithms* of their correſponding abſciſſæ, OP, OG, OR, &c. And the ſector LOM, or the ſegment LAPM meaſures the ratio OP to OA. The modulus of this ſyſtem of *logarithms* is the parallelogram OALB, which being ſuppoſed unity, theſe *logarithms* coincide with Napier's.

Hyperbolic ſectors meaſure ratios as circular ſectors or arches meaſure angles. See Maclaurin, l. c. Art. 177. L'Hoſpital Sect. Conic. art. 221.

By means of the hyperbola having the *hyperbolic logarithms*

of $1=0$, it is eafy to find the hyperbolic *logarithm* of 10. Let EZ and ET (*Tab.* III. *Analyfis*, *fig.* 66.) be the aſymptotes of the rectangular hyperbola YAI, whoſe parameter is $AP=PE=1$. Then, the area of the ſpace PABC will be the *hyperbolic logarithm* of $\frac{EC}{EP}$, that is, of EC; the area of the ſpace PA*bc* will be the *hyperbolic logarithm* of $\frac{EP}{Ec}$, that is of $\frac{1}{Ec}$; and the area of the ſpace *cb* BC will be the *hyperbolic logarithm* of $\frac{EC}{Ec}$; the right lines or ordinates CB and *cb* being ſuppoſed parallel to the aſymptote EZ. Now, to find theſe areas.

1. Put $Pc=x$, and $cb=y$; then, by the known property of the curve, $y=\frac{1}{1-x}$; which, drawn into $\dot{x}$, is $y\dot{x}=\frac{\dot{x}}{1-x}$ = the fluxion of Pb= (by throwing $\frac{\dot{x}}{1-x}$ into a ſeries,) $\dot{x}+x\dot{x}+x^2\dot{x}+x^3\dot{x}+x^4\dot{x}+x^5\dot{x}+x^6\dot{x}+x^7\dot{x}+x^8\dot{x}+x^9\dot{x}+x^{10}\dot{x}+x^{11}\dot{x}$, &c. therefore the fluent of this ſeries, *viz.* $x+\frac{1}{2}x^2+\frac{1}{3}x^3+\frac{1}{4}x^4+\frac{1}{5}x^5+\frac{1}{6}x^6+\frac{1}{7}x^7+\frac{1}{8}x^8+\frac{1}{9}x^9+\frac{1}{10}x^{10}+\frac{1}{11}x^{11}+\frac{1}{12}x^{12}$, &c. is=Pb.

2. Put $Pc=x$, and $CB=y$; then $y=\frac{1}{1+x}$, and $y\dot{x}=\frac{\dot{x}}{1+x}$ = the fluxion of PB= (by throwing $\frac{\dot{x}}{1+x}$ into a ſeries,) $\dot{x}-x\dot{x}+x^2\dot{x}-x^3\dot{x}+x^4\dot{x}-x^5\dot{x}+x^6\dot{x}-x^7\dot{x}+x^8\dot{x}-x^9\dot{x}+x^{10}\dot{x}-x^{11}\dot{x}$ &c. therefore the fluent of this ſeries, *viz.* $x-\frac{1}{2}x^2+\frac{1}{3}x^3-\frac{1}{4}x^4+\frac{1}{5}x^5-\frac{1}{6}x^6+\frac{1}{7}x^7-\frac{1}{8}x^8+\frac{1}{9}x^9-\frac{1}{10}x^{10}+\frac{1}{11}x^{11}-\frac{1}{12}x^{12}$ &c. is=PB.

Hence if $Pc=PC$, the area *cb*BC, *viz.* the ſum of Pb and PB, will be $=2x+\frac{1}{3}x^3+\frac{1}{5}x^5+\frac{1}{7}x^7+\frac{1}{9}x^9+\frac{1}{11}x^{11}+$ &c. And Pb—PB will be $=x^2+\frac{1}{2}x^4+\frac{1}{3}x^6+\frac{1}{4}x^8+\frac{1}{5}x^{10}+\frac{1}{6}x^{12}+$, &c. That is, if $Ec=.9$, and $cP=PC=.1$; then, by ſubſtituting .1 for x, we ſhall have *cb*B=.2006706954, &c. and Pb—PB=.0100503358, &c. half of which added to half *cb*B is .1053605156, &c. $=Pb=$ the *hyperbolic logarithm* of $\frac{1}{.9}$. And, if $Ec=.8$, and $cP=PC=v=.2$; then, by writing .2 for x, we have *cb*B=.4054651081, &c. = the *hyperbolic logarithm* of $\frac{1.2}{.8}$; and Pb—PB=.0408213945, &c. half of which ſubtracted from half *cb*B is .1823215567, &c. = PB = the *hyperbolic logarithm* of $\frac{1.2}{1}$ or 1.2; and this ſubtracted from *cb*B leaves .2231435513, &c. = Pb = the *hyperbolic logarithm* of $\frac{1}{.8}$. Therefore, by the nature of *logarithms*, the *hyperbolic logarithm* of $\frac{1}{.9}\times\frac{1.2}{.8}\times 1.2$, *viz.* of 2, is =.1053605156, &c. +.4054651081, &c. +.1823215567, &c. =.6931471806, &c. and, the *hyperbolic logarithm* of 2^3, *viz.* of 8, is $=3\times.6931471805$, &c. $=2.0794415416$, &c. and, the *hyperbolic logarithm* of $8\times\frac{1}{.8}$, *viz.* of 10, is $=2.0794415416$, &c. +.2231435513, &c. $=2.3025850929$, &c. Q. E. I. Rowe's Fluxions, p. 204, &c.

LOGARITHM, *imaginary*, is uſed for the *logarithm* of negative and imaginary quantities, ſuch as $a-\sqrt{-a}$, &c. Thus alſo the fluents of certain imaginary fluxionary expreſſions, ſuch as $\frac{\dot{x}}{x\sqrt{-1}}$, $\frac{a\dot{x}}{z\,b\,x\sqrt{-1}}$, &c. are *imaginary logarithms*. Euler Analyſ. infin. vol. i. p. 72, 74.

The expreſſion $\frac{\dot{x}}{x}$ repreſents the fluxion of the *logarithm* of x, and the fluent therefore of $\frac{\dot{x}}{x}$ is the *logarithm* of x; but no *logarithm* can repreſent the fluent of $\frac{\dot{x}}{x\sqrt{-1}}$, which is therefore called an *imaginary logarithm*.

However, when theſe *imaginary logarithms* occur in the ſolutions of problems, they may be tranſformed into circular arcs or ſectors; that is, the *imaginary logarithm*, or imaginary hyperbolic ſector becomes a real circular ſector. See Bernoulli, Oper. tom. i. p. 400, and p. 512. Mac Laurin's Fluxions, art. 762, ſeq. Walmeſley, Anal. des Mef. p. 63.

LOGARITHMIC *curve*. See CURVE.

LOGGERHEAT, in the *Sea Language*, denotes a large round ball of iron, with a long handle, for heating pitch.

LOGIC, the art of thinking juſtly; or of making a right uſe of our rational faculties, in defining, dividing, and reaſoning: or, as it is defined by an excellent writer on this ſubject, *logic* is the art of uſing reaſon well in our enquiries after truth, and the communication of it to others. Watts.

The word is Greek, λογικη, derived from λογος, *ſermo*, *diſcourſe*; in regard, thinking is only an inward, mental diſcourſe, wherein the mind converſes with itſelf.

Logic is alſo ſometimes called *dialectica*; and ſometimes the *canonical art*, as being a canon, or rule, for directing us in our reaſonings.

As, in order to think aright, it is neceſſary, that we apprehend, judge, diſcourſe, and diſpoſe, or methodize, rightly: hence perception or apprehenſion, judgment, diſcourſe or reaſoning, and diſpoſition, whence reſults method, become the four fundamental articles of this art; and it is from our reflections on theſe operations of the mind, that *logic* is, or ought to be, wholly drawn.

Lord Bacon divides *logic* into four branches, according to the ends propoſed in each: for a man reaſons, either to find what he ſeeks, or to judge of what he finds, or to retain what he judges, or to teach what he retains; whence ariſe ſo many arts of reaſoning; viz. the art of *inquiſition*, or invention; the art of *examining*, or judgment; the art of *preſerving*, or of memory; and the art of *elocution*, or delivery.

Logic, having been extremely abuſed, is now in ſome diſrepute. The ſchools have ſo clogged it with barbarous terms and phraſes, and have run it out ſo much into dry uſeleſs ſubtleties, that it ſeems rather intended to exerciſe the mind in wrangling and diſputation, than to aſſiſt it in thinking juſtly. It is true, in its original, it was rather intended as the art of cavilling, than of reaſoning; the Greeks, among whom it had its riſe, being a people who piqued themſelves mightily upon their being able to talk *ex tempore*; and to argue, by turns, on either ſide of the queſtion.—Hence their dialectici, to be always furniſhed with arms for ſuch rencounters, invented a ſet of words and terms, rather than rules and reaſons, fitted for the uſe of contention and diſpute.

Logic, then, was only an art of words, which frequently had no meaning, but ſerved well enough to hide ignorance inſtead of improving knowledge; to baffle reaſon inſtead of aſſiſting it, and to confound the truth inſtead of clearing it.—Much of that heap of words, and rules, which we have borrowed from the old *logic*, is of little uſe in life; and is ſo far out of the common uſage, that the mind does not attend to them without trouble; and finding nothing in them to reward its attention, it ſoon diſcharges itſelf, and loſes all ideas it had conceived of of them.

But *logic*, diſengaged from the jargon of the ſchools, and reduced into a clear and intelligible method, is the art of conducting the underſtanding in the knowledge of things, and the diſcovery of truth.

From its proper uſe we gain ſeveral very conſiderable advantages: for, 1. The conſideration of rules incites the mind to a cloſer attention and application in thinking; ſo that we hereby become aſſured, that we make the beſt uſe of our faculties. 2. We hereby more eaſily and accurately diſcover and point out the errors and defects in our reaſoning; for the common light of reaſon, unaſſiſted by *logic*, frequently obſerves an argumentation to be faulty, without being able to determine wherein the preciſe failure conſiſts. 3. By theſe reflections on the order and manner of the operations of the mind, we are brought to a more juſt and complete knowledge of the nature of our own underſtanding. See SOUL and UNDERSTANDING.

LOGICAL *concrete*. See CONCRETE.

LOGICAL *part*. See PART.

LOGISTA, the title of an officer at Athens, whoſe buſineſs was to receive and paſs the accounts of magiſtrates, when they came out of their office.

The *logiſtæ* were in number ten; they were elected by *lot*, and had ten euthyni, or auditors of accounts, under them.

LOGISTIC, or *logarithmic line*, a curve ſo called, from its properties and uſes, in conſtructing and explaining the nature of logarithms.

If the right line AX (*Tab. Analyſis*, *fig.* 37.) be divided into any number of equal parts, and to the points of thoſe diviſions, A, P, *p*, &c. be drawn lines continually proportional, the points, N, M, *m*, &c. form the *logiſtic* or *logarithmic*, *line*, or *curve*.

Here the abſciſſes AP, A*p*, &c. are the logarithms of the ſemiordinates PM, *pm*, &c.

Hence, if $AP=x$, $Ap=z$, $PM=y$, $pm=v$, and the logarithms of y and $x=ly$ and $v=lx$; conſequently $x:v=ly:lx$; that is, the denominators of the ratios AN: PM, and AN: *pm*, are to one another as the abſciſſes AP and A*p*.

Hence it follows, that there may be infinite other *logiſtic* lines invented: provided $x^m:v^n::ly:lx$, that any of the roots, or powers, may be the logarithms of the ſemiordinates. The *logiſtic* will never concur with the axis, except at an infinite diſtance; ſo that AX is its aſymptote. See *Logarithmic* CURVE.

LOGISTIC, *quadrature of the*. See QUADRATURE.

LOGISTIC, *or logarithmic spiral*, a line, whose construction is as follows.—Divide the quadrant of a circle into any number of equal parts, in the points N, *n*, *n*, &c. (*Tab. Analysis. fig.* 22.) and from the radii CN, C*n*, C*n*, &c. cut off C M, C*m*, C*m*, &c. continually proportional, the points M, *m*, *m*, &c. form the *logistic spiral*.

The arches, therefore, AN, A*n*, A*n*, &c. are the logarithms of the ordinates CM, C*m*, &c. whence also it follows, that there may be infinite *logistic spirals*.

LOGISTICA, or LOGISTICAL *arithmetic*, a denomination sometimes given to the arithmetic of sexagesimal fractions, used by astronomers in their calculations.

It was so called from a Greek treatise of one Barlaamus Monachus, who wrote about sexagesimal multiplication very accurately; and intitled his book Λογιστικη. This author Vossius places about the year 1350, but he mistakes the work for a treatise of algebra.

Shakerly, in his Tabulæ Britannicæ, has a table of logarithms adapted to the sexagesimal fractions; which, therefore, he calls, *logistical logarithms*; and the expeditious arithmetic of them, which is by this means obtained, and by which all the trouble of multiplication, and division, is saved, he calls *logistical arithmetic*.

LOGOGRAPHI, Λογοσγραφοι, among the *Ancients*, were the secretaries of the LOGISTÆ, and kept an account of the public revenues.

LOGOGRIPHUS, from the Greek λογος, *discourse*, and γριφος, or γρυπος, *net*, a kind of fymbol, or riddle, propofed to ftudents for their folution, in order to exercife and improve the mind.

The *logogriphus* ufually conſiſts in ſome equivocal alluſion, or mutilation of words; which, literally taken, ſignify ſomething different from the thing intended by it; ſo that it is a kind of medium between a REBUS and proper ENIGMA.

According to Kircher, *logogriphi* are a kind of canting arms: thus a perſon called Leonard, who bore in his arms a lion and nard, or ſpikenard, according to that father, made a *logogriphus*. Œdip. Ægypt.

In another place, the ſame author defines *logogriphus* to be an enigma; which, under one name, or word, will bear various meanings, by adding or retrenching ſome part of it.—This kind of enigmas is well known to the Arabs; among whom are authors who treat expreſly of it.

LOGOTHETA, an officer under the emperors of the Eaſt, who kept an account of the various branches of public and private expence.

There were ſeveral kinds of them diſtinguiſhed by the particular branch they ſuperintended, as the *logotheta τη δρομε*, or *poſt-maſter general*; *logotheta των οικιακων*, or *maſter of the houſehold*, &c.

LOHOCH. See LOCH.

LOINS, *lumbi*, in *Anatomy*, that part of the body about the reins, properly the lower part of the ſpine of the back, compoſed of five vertebræ, larger than thoſe of the back, and ſerving them as a baſe; having their articulations pretty looſe, that the motion of the *loins* may be more free. See *Tab. Anat. (Oſteol.) fig.* 3. *n.* 12. *fig.* 7. *n.* 16. *fig.* 9. * *fig.* 11. See alſo SPINE, and VERTEBRA.

LOKE, in *Mythology*, the name of one of the deities of the northern nations, anſwering to the Arimanes among the Perſians, whom they repreſent as at enmity both with Gods and men, and the author of all the evils which deſolate the univerſe. *Loke* is deſcribed in the EDDA as producing the great ſerpent which encircles the world; which ſeems to have been intended as an emblem of corruption or ſin: he alſo gives birth to Hela or death, the queen of the infernal regions; and alſo to the wolf Fenris, that monſter, who is to encounter the Gods and deſtroy the world. North. Ant. vol. ii. p. 85, &c.

LOLIUM, in *Botany*, *darnel*, or *rye-graſs*, a genus of the *triandria digynia* claſs, with a ſingle-leaved, fixed, many-flowered empalement.

The ancients uſed the word *lolium*, as the name of a diſeaſed ſtate of corn of any kind, and have given accounts of ſeveral ſorts of diſeaſed appearances, to all of which they indifferently gave this name. See GRASS.

LOLLARDS, in *Eccleſiaſtical Hiſtory*, a religious ſect, differing in many religious points from the church of Rome, which aroſe in Germany about the beginning of the fourteenth century; ſo called, as many writers have erroneouſly imagined, from Walter Lollard, who began to dogmatize in 1315, and was burnt at Cologn: but it is evident that Lollard was no ſurname, but merely a term of reproach applied to all heretics who concealed the poiſon of error under the appearance of piety.

The monk of Canterbury derives the origin of the word *Lollard*, among us, from *lolium*, *a tare*; as if the *Lollards* were the tares ſown in Chriſt's vineyard.—Abelly ſays, that the word *Lollard* ſignifies *praiſing God*, from the German *loben*, *to praiſe*, and *herr*, *Lord*; becauſe the *Lollards* employed themſelves in travelling about from place to place, ſinging pſalms and hymns.

Others, much to the ſame purpoſe, derive *lollhard*, *lullhard*, or *lollert lullert*, as it was written by the ancient Germans, from the old German word *lullen*, *lollen*, or *lullen*, and the termination *hard*, with which many of the High Dutch words end. *Lollen* ſignifies to ſing with a low voice, and, therefore, *Lollhard* is a ſinger, or one who frequently ſings; and in the vulgar tongue of the Germans, it denotes a perſon who is continually praiſing God with a ſong, or ſinging hymns to his honour. The Alexians or CELLITES were called *Lollards*, becauſe they were public ſingers, who made it their buſineſs to inter the bodies of thoſe who died of the plague, and ſang a dirge over them in a mournful and indiſtinct tone as they carried them to the grave. The name was afterwards aſſumed by perſons that diſhonoured it; for we find, among thoſe *Lollards* who made extraordinary pretences to piety and religion, and ſpent the greateſt part of their time in meditation, prayer, and ſuch acts of piety, there were many abominable hypocrites, who entertained the moſt ridiculous opinions and concealed the moſt enormous vices under the ſpecious mark of this extraordinary profeſſion. And many injurious aſperſions were propagated againſt thoſe who aſſumed this name, by the prieſts and monks; ſo that by degrees, any perſon who covered hereſies or crimes under the appearance of piety, was called a *Lollard*. Thus the name was not uſed to denote any one particular ſect, but was formerly common to all perſons and all ſects, who were ſuppoſed to be guilty of impiety towards God or the church, under an external profeſſion of extraordinary piety. However, many ſocieties, conſiſting both of men and women, under the name of *Lollards*, were formed in moſt parts of Germany, and Flanders, and were ſupported partly by their manual labours, and partly by the charitable donations of pious perſons. The magiſtrates and inhabitants of the towns, where theſe brethren and ſiſters reſided, gave them particular marks of favour and protection, on account of their great uſefulneſs to the ſick and needy. They were thus ſupported againſt their malignant rivals, and obtained many papal conſtitutions, by which their inſtitute was confirmed, their perſons exempted from the cognizance of the inquiſitors, and ſubjected entirely to the juriſdiction of the biſhops; but as theſe meaſures were inſufficient to ſecure them from moleſtation, Charles, duke of Burgundy, in the year 1472, obtained a ſolemn bull from pope Sixtus IV. ordering that the CELLITES, or *Lollards*, ſhould be ranked among the religious orders, and delivered from the juriſdiction of the biſhops; and pope Julius II. granted them yet greater privileges in the year 1506. Moſheim informs us, that many ſocieties of this kind are ſtill ſubſiſting at Cologn, and in the cities of Flanders, though they have evidently departed from their ancient rules. Eccl. Hiſt. vol. iii. p. 188. 8vo.

Lollard and his followers rejected the ſacrifice of the maſs, extreme unction, and penances for ſin; arguing, that Chriſt's ſufferings were ſufficient. He is likewiſe ſaid to have ſet aſide baptiſm, as a thing of no effect; and repentance, as not abſolutely neceſſary, &c.—In England, the followers of Wickliffe were called, by way of reproach, *Lollards*, from ſome affinity there was between ſome of their tenets; though others are of opinion, that the Engliſh *Lollards* came from Germany.

They were ſolemnly condemned by the archbiſhop of Canterbury, and the council of Oxford.

LOMBAIRE *externe*, in *Anatomy*, a name given by Winſlow, and ſome other of the French writers, to a muſcle, called by the earlier authors the *primus dorſi*, and now generally known by the name *quadratus lumborum*. The French call this the external lumbal muſcle, in diſtinction from the *pſoas magnus*, which they call the *lombaire interne*.

LOMBAIRE *interne*, in *Anatomy*, a name given by Winſlow, and ſome other French writers, to the muſcle generally called *pſoas magnus*.

LOMENTUM, a word uſed by the old writers on medicine, to expreſs a meal made of beans, or bread made of this meal, and uſed as a waſh. See DETERSORIUM.

Others have applied it to the French chalk, or morochthus, uſed by the ſcowerers of cloaths, which is brought over in large cakes, reſembling loaves or cakes of bread.

LOMMIA, in *Ornithology*, the name of a web-footed water-fowl common on the Engliſh ſhores, and called in different places the *guillem*, *guillemot*, *ſea-hen*, *kiddow*, and *ſcout*: the laſt name, however, is ſomewhat equivocal as the Scotch call the common *razor-bill* by this name.

The *lommia*, or kiddaw, or COLYMBUS *troile* of Linnæus, is much like the razor-bill, but it is larger, being of the full

full size of a common duck; its head, neck, wings, back, and tail, as also the upper part of its throat, are of a mixed colour, between brown, black, and grey; its breast, belly, and lower part of its throat are white, and its wings are variegated with a mixture of white; its bill is straight, black and sharp, and is three fingers breadth long, and rounded; its legs are placed far behind, and it has no hinder toes. It is very plentiful on the high cliffs on several of our coasts, and builds on the naked rocks there. It is a very simple bird, for when it is shot at and sees some of its companions killed by it, it will not quit the rock. Ray's Ornithol. p. 244.

There is a better variety of this bird, which frequents the Welsh coasts in winter; and which haunt the frith of Forth in pursuit of sprats, where they are called *marrots*; but they all retire before spring.

LONCHITIS, in *Botany*. See SPLEENWORT.

LONCHOTON, a word used by some chemical writers to express the best and purest kinds of native vitriol, of the green or bluish green kinds.

LONDON *pride*, in *Botany*. See SAXIFRAGE.

LONG *accent*, in *Grammar*. See ACCENT.

LONG *hand*. See *Long* HAND.

LONG *measure*. See MEASURE.

LONG *muscles*, in *Anatomy*. See LONGUS.

LONG-*jointed*, in the *Manege*. A horse is said to be *long-jointed*, whose pastern is slender and pliant. *Long-jointed* horses are wont to have wind-galls.

LONG-*legs*, in *Natural History*. See TIPULA.

LONGA, *long*, in the *Italian Music*, is a character marked thus 𝅜, containing four semi-breves, in common time, and consequently eight minims, unless tied to a breve; for in that case, in such case, see LIGATURE.

LONGANON, a name given by some authors to the intestinum rectum.

LONGEVITY, length of life. See LIFE and AGE.

From the different *longevities* of men in the beginning of the world, after the flood, and in these ages, Mr. Derham draws a good argument for the interposition of a Divine Providence.

Immediately after the creation, when the world was to be peopled by one man and woman, the ordinary age was 900 years and upwards,—Immediately after the flood, when there were three persons to stock the world, their age was cut shorter; and none of those patriarchs, but Shem, arrived at 500. In the second century we find none that reached 240; in the third, none, but Terah, that came to 200 years; the world, at least a part of it, by that time being so well peopled, that they had built cities, and were cantoned out into distant nations. By degrees, as the number of people increased, their *longevity* decreased, till it came down, at length, to 70 or 80 years; and there it stood, and has continued to stand, ever since the time of Moses. This is found a good medium, and, by means hereof, the world is neither overstocked, nor kept too thin; but life and death keep a pretty equal pace.

That the common duration of man's life has been the same in all ages since the world was peopled, is plain, both from sacred and profane history. To pass by others, Plato lived to 81, and was accounted an old man: and the instances of *longevity* produced by Pliny, lib. vii. cap. 48. as very extraordinary, may most of them be paralleled in modern histories, particularly in Dr. Plott's Nat. Hist. of Ox. and Staff.—Among others, he tells of twelve tenants to the same person, who made up 1000 years; to say nothing of old Parr, who lived 152 years 9 months; nor of H. Jenkins, of Yorkshire, who lived 169 years; or of the countess of Desmond, or Mr. Eckleston, both of Ireland, who each exceeded 140 years.

LONGIMETRY, the art of measuring lengths, both accessible as roads, &c. and inaccessible, as arms of the sea, &c.

Longimetry is a part of trigonometry, and a dependent on geometry, in the same manner as altimetry, planimetry, stereometry, &c.

The art of *longimetry* see under the names of the instruments used in it, particularly THEODOLITE, CHAIN, DISTANCE, &c.

LONGISSIMUS *dorsi*. See DORSI.

In conjunction with some others, this helps to keep the body erect.

LONGISSIMUS *Oculi*. See OBLIQUUS *superior*.

LONGITUDE *of the earth*, is sometimes used to denote its extent from west to east, according to the *direction* of the equator.

By which it stands contradistinguished from the *latitude of the earth*, which denotes its extent from one pole to the other.

LONGITUDE *of a star*, in *Astronomy*, is an arch of the ecliptic, counted from the beginning of Aries, to the place where a star's circle of *longitude* cuts the ecliptic.

The *longitude* of a star, as *S* (Tab. *Astronomy*, fig. 14. n. 2.) is an arch of the ecliptic ♈L, comprehended between the beginning of Aries, and the circle of *longitude* TM, drawn through the centre of the star *S*.

Longitude stands in the same relation to the ecliptic, that *right ascension* does to the equator.

In which sense, the longitude of a star amounts to much the same, as the star's place in the ecliptic, reckoned from the beginning of Aries; which to find, see PLACE *of the sun, or star*.

LONGITUDE *of the sun*, or a *star*, from the next equinoctial point, is the number of degrees, and minutes they are from the beginning of Aries, or Libra, either before or after them; which can never be more than 180 degrees.

LONGITUDE, *geocentric, of a planet*. See GEOCENTRIC.

LONGITUDE *of a place*, in *Geography*, is its distance from some first meridian; or an arch of the equator, intercepted between the meridian of the place, and the *first* MERIDIAN. See a table exhibiting the quantity of each degree of *longitude* in each parallel of latitude, under DEGREE.

LONGITUDES, in *Navigation*, is the distance of a ship, or place, east or west, from another, counted in degrees of the equator. If this distance be counted in leagues, or miles, or in degrees of the meridian, and not in those proper to the parallel of latitude, it is usually called DEPARTURE.

To discover an exact method of finding the *longitude* at sea, is a problem that has extremely perplexed the mathematicians of these two last ages; and for the solution whereof, great rewards have been publicly offered by the English, French, Dutch, and other nations; this being the only thing wanting to render navigation perfect.

In the year 1598, Philip the third, king of Spain, offered a reward of 1000 crowns for the solution of this problem; this noble example was followed by the States General, who offered 10,000 florins; and in 1635, John Morin, professor of mathematics at Paris, proposed a method of resolving it to cardinal Richlieu; though the commissioners, who were appointed to examine this method, judged it insufficient, on account of the imperfection of the lunar tables. cardinal Nazarin, in 1645, procured for him a pension of 2000 livres. In 1714, an act was passed in the British parliament, appointing and empowering certain commissioners to make out a bill for a sum not exceeding 20000*l.* towards making necessary experiments; and also granting a reward to the person who should discover the *longitude* at sea, proportioned to the degree of accuracy that might be attained by such method; viz. a reward of 10,000*l.* if it determines the said *longitude* to one degree of a great circle, or sixty geographical miles; 15,000*l.* if it determines the same to two-thirds of that distance; and 20,000*l.* if it determines it to half that distance. It is added, that one moiety or half part of such rewards or sum, shall be due and paid when the said commissioners, or the major part of them, do agree, that any such method extends to the security of ships, within eighty geographical miles from the shores, which are places of the greatest danger; and the other moiety or half part, when a ship, by the appointment of the said commissioners, or the major part of them, shall thereby actually sail over the ocean, from Great Britain to any such port in the West Indies, as those commissioners or the major part of them shall chuse, or nominate for the experiment, without losing her *longitude* beyond the limits above mentioned. 12 Ann. cap. 15. See also stat. 14 Geo. II. cap. 30. 26 Geo. II. cap. 25. By stat. 14 Geo. III. all former acts concerning the *longitude* at sea are repealed, except so much of them as relates to the appointment and authority of the commissioners thereby constituted, and also such clauses as relate to the contracting, printing, publishing, &c. of nautical almanacs, and other useful tables; and it is enacted, that any person, who shall discover any method for finding the *longitude* by means of a time-keeper, the principles of which have not hitherto been made public, shall be intitled to the reward of 5000*l.* if, after certain trials prescribed by the commissioners, such method shall enable a ship to keep her *longitude*, during a voyage of six months, within sixty geographical miles, or a degree of a great circle; to 7500*l.* if it serves to keep her *longitude* for the same time, within forty geographical miles, or two-thirds of a degree of a great circle; or to a reward of 10,000*l.* if, for that time, it enables her to keep her *longitude* within thirty geographical miles, or half a degree of a great circle. If the method proposed shall be by means of improved lunar tables, the author of such tables shall be intitled to a reward of 5000*l.* when they shew the distance of the moon from the sun and stars within 15″ of a degree, answering to about 2′ of *longitude*, after making an allowance of half a degree for the errors of observation, and under certain restrictions, and after comparison with astronomical observa-

tions for a period of 18½ years, which is deemed the period of the irregularities of the lunar motions. In case any other method shall be proposed for finding the *longitude* at sea, beside those already mentioned, the author shall be intitled to 5000*l.* if it shall determine the faid *longitude* within one degree of a great circle, or fixty geographical miles; to 7500*l.* if it fhall determine the fame to two-thirds of that diftance; and to 10,00*l.* if it fhall determine the fame to one half of that diftance. The commiffioners are impowered by this act to make out bills upon the treafurer of the navy for any fums of money, which they fhall think neceffary for making experiments with relation to any probable difcovery or improvement. It is obfervable, that there is an ambiguity in the limits preferibed by this and other acts, relating to the *longitude*, which may poffibly be the occafion of difputes; for fixty geographical miles or one degree of a great circle may make either one or one hundred and eighty degrees of *longitude*; and, therefore, the determination ought to have been expreffed in minutes of the equator.

Various are the attempts that authors have made for this purpofe, and various the methods they have propofed, which have been attended with different degrees of fuccefs. What moft of them aim at is, a method of determining the difference of time between any two points on the earth; for the *longitude* of any place is an arc of the equator intercepted between the faid meridian and the meridian of that place, and this arc is proportional to the quantity of time which the fun requires to move from the one meridian to the other; and every fifteen degrees of the equator anfwering to an hour, i. e. one degree to 4 minutes of time, and one minute of a degree to 15 feconds of time; the difference of time being known, and turned into degrees, will give the *longitude*, and *vice verfa*. This fome have attempted to effect by clocks, watches, and other automata: for, if a clock or watch was fo contrived, as in all feafons and in all places to go uniformly; fuch a watch being regulated to London or Greenwich time, would always fhew the time of the day at London or Greenwich, then the time of the day under any other meridian being found, the difference between that time and the London or Greenwich time correfponding, would give the difference of *longitude*.

Gemma Frifius, in a tract intitled De Principiis Aftronomiæ et Geographiæ, printed at Antwerp in 1530, feems to have been the firft who fuggefted the method of finding the *longitude* at fea by means of watches, or time-keepers; which machines were then, as he fays, but lately invented. After him, Metius, about 1631, and fome others attempted it; but the ftate of watch-making was then too imperfect for this purpofe. Dr. Hooke and M. Huygens, about the fame time, *viz.* about the year 1664, applied the invention of the pendulum-fpring to watches; and employed it for the purpofe of difcovering the *longitude* at fea. Some difputes, however, between the former of thofe gentlemen and the Engliſh miniſtry, prevented any experiments being made with watches conſtructed by him; but many experiments were made with watches conſtructed by M. Huygens. Major Holmes, in a voyage from the coaſt of Guinea in 1665, predicted with one of his watches, the *longitude* of the iſland of Fuego to a very great degree of accuracy: this ſucceſs encouraged Huygens to improve the ſtructure of his watches, (ſee Phil. Tranſ. N° 47, for May, 1669), but experience ſoon convinced him, that unleſs methods could be diſcovered for preſerving the regular motion of ſuch machines, and preventing the effects of heat and cold, and other diſturbing cauſes, they could never anſwer the intention of diſcovering the *longitude*; and on this account his attempts failed. The firſt perſon who turned his thoughts this way, after the public encouragement held out by the act of 1714, was Henry Sully, an Engliſhman; who in 1714, printed at Vienna, a ſmall tract on the ſubject of watch-making, and afterwards removing to Paris, employed himſelf in improving time-keepers for the diſcovery of the *longitude*. He is ſaid to have greatly diminiſhed the friction, and to have rendered that which remained uniform. The greater part of what is yet known of watch-making in France, is principally to be attributed to him; for the famous Julien le Roy was his pupil, and owed moſt of his inventions to him, which he afterwards perfected and executed; and this gentleman, his ſon, and M. Berthoud are the only perſons in France, who have turned their thoughts this way ſince the time of Sully. Several watches, made by the two latter artiſts, have been tried at ſea, at the expence of the king of France, and voluminous accounts have been publiſhed of theſe trials; but it does not appear that they afford any conſiderable advantage with regard to the main object. In the year 1726, our own countryman, Mr. John Harriſon, produced a time-keeper of his own conſtruction, which was found to keep time ſo exactly with the heavens, as not to err above one ſecond in a month, for ten years together; and in the year 1736, this machine was tried, on board one of his majeſty's ſhips, in a voyage to and from Liſbon; and by its exact meaſure of time, in the ſhip's return from Liſbon, corrected an error of almoſt a degree and a half, in the computation of the ſhip's reckoning. Mr. Harriſon, in conſequence of this ſucceſs, received public encouragement to proceed; and he made three other time-keepers, every one of which was more accurate, and better adapted to the purpoſe of meaſuring time truly at ſea, than the former. The ſecond of his machines was finiſhed in 1739; the third in 1758; and the fourth in 1761: this laſt proved ſo much to Mr. Harriſon's ſatisfaction, that he applied to the commiſſioners of the board of *longitude* for orders to make a trial of this inſtrument in a voyage to ſome port in the Weſt Indies, according to the directions of the ſtatute of 12th of Anne above cited. Accordingly, Mr. William Harriſon, ſon of the inventor, embarked on board his majeſty's ſhip Deptford, in November, 1761, with this fourth time-keeper, on a voyage for Jamaica; and the *longitude* of the iſland, as ſhewn by the time-keeper, on his arrival there, differed but one minute and a quarter of the equator from the true *longitude*, deduced from aſtronomical obſervations. The time-keeper alſo pointed out the *longitudes* of the ſeveral places, which they law in the courſe of the voyage, in a very exact manner. Mr. Harriſon, junior, returned to England, with the time-keeper, in the latter end of March, 1762; and found that it had erred, in the whole, from its ſetting out to its return to England, no more than 1′ 54″ in time, or 28′ minutes of *longitude*; whereas the act requires no greater exactneſs than 30 minutes, in a voyage to the Weſt Indies. Mr. Harriſon now claimed the whole reward of 20,000*l.* offered by the ſaid act; but ſome doubts ariſing in the minds of the commiſſioners concerning the true ſituation of the iſland of Jamaica and the manner in which the time at that place had been found, as well as at Portſmouth; and it being farther ſuggeſted by ſome, that although the time-keeper had proved to be right at Jamaica and after its return to England, it was by no means a proof that it had been always ſo in the intermediate times, another trial was propoſed in a voyage to the iſland of Barbadoes, in which precautions were taken to obviate as many of theſe objections as poſſible. Accordingly, the commiſſioners previouſly ſent out proper perſons to make aſtronomical obſervations at that iſland, which, when compared with other correſponding ones made in England, would determine, beyond a doubt, its true ſituation. Mr. William Harriſon again ſet out with his father's time-keeper, in March 1764, the watch having been compared with equal altitudes, before he ſet out, at Portſmouth, and arrived at Barbadoes about the middle of May; where, on comparing it again with equal altitudes of the ſun, it was found to ſhew the difference of *longitude* between Portſmouth and Barbadoes, 3ʰ 55′ 3″; the true difference of *longitude* between theſe places, reſulting from aſtronomical obſervations, being 3ʰ 54′ 20″, ſo that the error of the watch was 43″, or 10′ 45″ of *longitude*. The watch gained at the rate of 2″,58 a day, on mean time, from February 29th to March 21ſt, at Portſmouth, and loſt at the rate of 2″,8 a day, from May 14th to May 17th, at Barbadoes: and from its departure from Surry-ſtreet, in the Strand, where it had been compared with Mr. Short's regulator, till its arrival there again, after one hundred and fifty-ſix days, it had gained fifty-four ſeconds. In conſequence of this and the former trials, Mr. Harriſon received a moiety of the reward offered by the 12th of Queen Anne, on his explaining the principles by which his time-keeper was conſtructed, and delivering this as well as the former three, to the commiſſioners of the *longitude*, for the uſe of the public. He was alſo promiſed the other moiety of the reward, when other time-keepers were made, on the ſame principles, either by himſelf or others, which performed equally well with that which he had laſt made. This laſt time-keeper was alſo ſent down to the royal obſervatory at Greenwich, to be tried there, under the direction of the Rev. Mr. Maſkelyne, his majeſty's aſtronomer royal. It did not appear, however, that during the time of this trial, the watch went with the regularity that was expected, which gave reaſons for apprehending that the performance even of the ſame watch, was not at all times equal; and conſequently that little certainty could be expected in the performance of different ones. Moreover, the watch was now found to go faſter than it did during its voyage to and from Barbadoes, by about eighteen or nineteen ſeconds in twenty-four hours; but this circumſtance was accounted for by Mr. Harriſon; who informs us, that he had altered the rate of its going by trying ſome experiments, which he had not time to finiſh before he was ordered to deliver up the watch to

the board. Soon after this trial, the commissioners of *longitude* agreed with Mr. Kendall, one of the watch-makers appointed by them to receive Mr. Harrison's discoveries, to make another watch on the same construction with this, in order to determine whether other watch-makers could make them from the account which Mr. Harrison had given, as well as himself. The event proved the affirmative; for the watch produced by Mr. Kendall, in consequence of this agreement, went considerably better than that which had been made by Mr. Harrison himself. This watch was sent out with Capt. Cooke in his second voyage towards the South Pole and round the world, in 1772, 1773, 1774, and 1775, to be tried under the care of Mr. Wales, employed by the board of *longitude* for that purpose. The only defect which appears to have been in this watch is, that its rate of going was continually accelerated; but in the 38 years, during this trial, it never amounted to 14′ 2 a day. In consequence of the going of this watch, the house of commons were pleased, in 1774, to order the other moiety of the reward, offered by the act of the 12th of queen Anne, to be given to Mr. Harrison, and to pass the act above recited. Mr. Arnold has lately constructed a watch, which seems to be more accurate than any of the former; though it has not yet been tried at sea. During thirteen months of trial from February 1779, to February 1780, the greatest difference between the rates at which the watch went on any two days, was 6″,69: the greatest difference between its rates of going on any day and the next to it, was 4″,13; so that the greatest error it would have committed in the difference of *longitude*, on any one day, would have been very little more than one minute; which, as Mr. Arnold observes, in determining the *longitude* daily, to as great precision as the latitude can, in general, be determined. If the mean rate at which it went during the month of February 1779, be taken as a standard rate with which we may compare its going for the following twelve months, the greatest error which it would have committed in the *longitude* shewn by it, would have been 2′, 33″, 2, or 38′ 18″ in *longitude*: the parts of this machine, which are to counteract the effects of heat and cold, seem to be most exactly adjusted; and the balance is so adjusted likewise, that it is capable of going alike in the different positions into which the watch may be placed. Account kept during thirteen Months in the Royal Observatory at Greenwich, of the going of a Pocket chronometer, made on a new Construction, by John Arnold, &c. 4to. 1780. See TIME-*keeper* and PENDULUM.

Others have proposed various astronomical methods for finding the *longitude* in the heavens; for, if the exact times of any celestial appearance be known for two places, the difference of those times gives that of the *longitude* of those places. These methods chiefly depend on having an ephemeris or almanac, suited to the meridian of some place, suppose Greenwich, for which the *Nautical* ALMANAC is fitted, which ephemeris shall contain for every day of the year the sun's place, right ascension, declination, the times of the planets passing the meridian, as also their rising and setting, the times of the eclipses of the sun and moon, together with those of Jupiter's satellites, the distance of the moon from the sun, and some zodiacal stars at certain times; and, in general, the times when any other remarkable celestial appearances may be seen at the place for which the ephemeris is calculated: therefore, if the hour and minute be known, wherein any of the same phenomena are observed in any unknown place, the difference between the hour and minute of that place, and that other to which the tables are calculated, and consequently, the difference of their meridians, and their *longitude*, from each other, are known also.

Now the difficulty here does not consist in the exact finding of the time, which is easily had, from the sun's altitude, or azimuth, but the defect lies in the paucity of proper appearances, capable of being thus observed; for all slow motions (v. gr. that of Saturn) are at once excluded, as shewing but little difference in a considerable space of time; and it being here required, that the phenomenon be sensibly varied in two minutes time, an error of two minutes in time produces another of thirty miles in *longitude*.—Now there are no phenomena in the heavens that have these requisites, excepting the several stages of an eclipse of the moon: her *longitude*, or place in the zodiac; her distance from the fixed stars, or appulse to them; her ingress into the ecliptic; or the points of her orbit, where that cuts the ecliptic, and the conjunction, distances, and eclipses of Jupiter's satellites.—Of each of which in their order.

1. The method, by the eclipses of the moon, is very easy, and sufficiently accurate, if there were but eclipses every night.—At the moment wherein we see the beginning, or middle, or end of a lunar eclipse by a telescope, we have nothing to do but take the altitude, or azimuth, of some fixed star, from which the hour and minute are easily found; or without the altitude, if the star be in the meridian.—This hour and minute, therefore, thus found, and compared with that expressed in the tables, gives the *longitude*.

But as the beginning or end of an eclipse of the moon cannot be generally observed nearer than one minute, and sometimes two or three minutes of time, the *longitudes* of places cannot be certainly determined by this method from a single observation of the beginning or end, nearer than a degree. However, if both the beginning and end of the eclipse be observed, a considerably greater degree of exactness will be attained.

2. The moon's place in the zodiac is a phenomenon more frequent than that of her eclipses; but then the observation thereof is difficult, and the calculus intricate and perplexed, by reason of two parallaxes; so that it is scarce practicable, to any tolerable degree of accuracy. Indeed, by waiting till the moon comes into the meridian of the place, and then taking the altitude of some remarkable star (the altitude being supposed to be first known), from this altitude, and the latitude, we shall be able to find the time pretty accurately; though it will be better to do it by some star in the meridian. Now the time being found, it will be easy to find what point of the ecliptic is then in the meridian, or mid-heaven. Thus we shall have the moon's place in the zodiac, corresponding to the time of our place. Then in the ephemeris we find what hour it is in the meridian of the ephemeris, when the moon is in that part of the zodiac: thus we shall have the hour and minute of the two places for the same time; the difference of which will give the difference of *longitude*.

3. In regard there are many times when the moon cannot be observed in the meridian, there is, therefore, another still more frequent phenomenon, from which the *longitude* is sought; viz. the moon's appulse, and recess from the fixed stars; for from thence the moon's true place may be investigated for the given time of observation.

The first person who recommended the investigation of the *longitude* from observing the distance between the moon and some star, is said to have been John Werner, of Nuremberg, who printed his annotations on the first book of Ptolemy's Geography, in 1514: Peter Apian, professor of mathematics at Ingolstadt, in 1524; Orontius Finè, of Briançon, about 1530; Gemma Frisius, at Antwerp, in 1530; Nonius or Pedro Nunez, in 1560; and Kepler, in 1620, all suggest and recommend the same method. In 1665, king Charles II. erected the observatory at Greenwich, and appointed Mr. Flamsteed his astronomical observer, with this express command, that he should apply himself with the utmost care and diligence to the rectifying the table of the motions of the heavens, and the places of the fixed stars, in order to find out the so much desired *longitude* at sea, for perfecting the art of navigation. To the fidelity and industry with which Mr. Flamsteed executed his commission, we are in a great measure indebted for that curious theory of the moon, which was afterwards formed by the immortal Newton. This incomparable philosopher made the best use which human sagacity could make of the observations with which he was furnished; but, as these were interrupted and imperfect, the difference of Sir Isaac's theory from the heavens would sometimes amount at least to five minutes. Dr. Halley employed much time on this subject; and a starry zodiac was published under his direction, containing all the stars to which the moon's appulse can be observed: but for want of proper instruments and correct tables, he could not proceed in making the necessary observations: in a paper on this subject he expresses his hope, that the instrument just invented by Mr Hadley, might be applied to taking angles at sea with the desired accuracy. See Phil. Trans. N° 421. This great astronomer, and after him the abbé de la Caille, and others, have reckoned the best astronomical method for finding the *longitude* at sea, to be that wherein the distance of the moon from the sun, or from a star is used; for the moon's daily mean motion being about thirteen degrees, her hourly mean motion is about half a degree, or one minute of a degree in two minutes of time; and so an error of one minute of a degree in position will produce an error of two minutes in time, or half a degree in *longitude*: and if by observation it is determined what part of her daily motion the moon has run through during the interval between a certain point of time under a known meridian, and the instant of time when the observations are made on her, under an unknown meridian, then her daily motion at that time will have, to the part thereof determined by observation, the same ratio, which twenty-four hours has to the interval of time taken to definite that arc. From the very considerable improvements made by Sir Isaac Newton in the theory of the moon, and more lately by Mr. Euler, and others on his

principles, M. Tobias Mayer, professor, of Gottingen, was enabled to calculate lunar tables more correct than any that were before published, and he has succeeded so far as to give the moon's place within one minute of the truth. This has been proved by a comparison of the tables with the observations made at the Greenwich observatory by the late Dr. Bradley, and by the present astronomer royal. These tables, for which the widow of Mr. Mayer was rewarded by the British parliament, were published in 1770, by Mr. Maskelyne, by order of the commissioners of *longitude*. Mr. Maskelyne, in his voyage to St. Helena, in 1761, made use of these tables, and found them to answer for the discovery of the *longitude*, within a degree; and in order to facilitate the general use of them, he proposed a nautical ephemeris, the scheme of which was adopted by the commissioners of *longitude*, and first executed in the year 1767: and the publication has been regularly continued ever since. But as the rules that were given in the appendix to one of those publications, for correcting the effects of refraction and parallax were deemed too difficult for general use, they were reduced to tables: so that by the help of the ephemeris, these tables, and others that are provided, the calculations relating to the *longitude*, which could not be performed by the most expert mathematician in less than four hours, may now be completed with great ease and accuracy in half an hour. Mr. Maskelyne observes, that the error of Mr. Mayer's last lunar tables seldom exceeds 1′ at the most, and seldom amounts to 20″; and, therefore, the uncertainty hence arising in the determination of the *longitude*, can scarcely exceed half a degree, and generally will not exceed ten miles. As this method of determining the *longitude* depends on the use of the tables, annually published for this purpose, we shall refer those who wish for farther information, to the instructions that accompany them, and particularly to those that are annexed to the tables requisite to be used with the astronomical and nautical Ephemeris, 1769, p. 241, &c.

4. To find the *longitude* by the moon's ingress into the eclipse, observe the moment of that ingress: then, in the ephemeris, see what hour it is in the meridian of the ephemeris, when that ingress happens. The difference between these times gives the difference of *longitude*. See MOON.

5. The phænomena of Jupiter's satellites have been generally preferred to those of the moon, for finding the *longitude*; because the former are less liable to parallaxes; and do, farther, afford a very commodious observation, in every situation of that planet above the horizon. Their motion is very swift, and must be calculated for every hour; and, for that reason, they are not found in the common ephemerides, but are had elsewhere; particularly in the Nautical Ephemeris. These satellites of Jupiter were no sooner discovered by Galileo, in his Sydereus Nuncius, first printed at Venice, in 1610, than the frequency of their eclipses recommended them for this purpose; and among those who attempted this subject, none were more successful than Cassini. This great astronomer, in 1688, published at Bologna, tables for calculating the appearances of their eclipses, with directions for finding thence the *longitudes* of places; and being invited to France by Lewis XIV. he there published corrected tables in 1693. But the mutual attractions of the satellites rendering their motions very irregular, the tables soon became useless; insomuch that they require to be renewed from time to time, which has been performed by ingenious persons, as Dr. James Pound, Dr. James Bradley, M. Cassini the son, and M. Peter Wargentin. Wargentin's tables are much esteemed; they were first published at Stockholm, in the Acta Societatis Regiæ Scientiarum Upsaliensis, for the year 1743; and since more correctly from a new copy of the author's at Paris, in 1755, by M. de la Lande. They are also published in the Nautical Almanac for 1771 and 1779, &c.

Now, to find the *longitude* by these satellites, with a good telescope observe a conjunction of two of them, or of one of them with Jupiter, or any other the like appearance; and, at the same time, find the hour and minute from the meridian altitude of some star, or by means of a clock or watch, previously regulated for the place of observation; then, consulting tables of the satellites, observe the hour and minute wherein such appearance happens in the meridian of the place to which the tables are calculated. The difference of time, as before, will give the *longitude*.

The eclipses of the first and second of Jupiter's satellites are the most proper for this purpose: and the best telescopes for observing them are common refracting telescopes, from fifteen to twenty feet, reflecting telescopes of eighteen inches or two feet, and telescopes of Mr. Dollond's construction, with two object glasses, from five to ten feet; or, which are still more convenient, those of three feet and a half, constructed with three object glasses, which are as manageable as reflecting telescopes, and perform as much as those of ten feet, with two object glasses. As these eclipses happen almost daily, they afford the most ready means of determining the *longitude* of places at land, and have very much contributed to the modern improvements in geography. If it were possible to observe them with sufficient accuracy in a ship under sail, they would be of great service in ascertaining its *longitude* from time to time. In order to remedy the inconvenience to which these observations are liable from the agitation of the ship, Mr. Christopher Irwin invented what he calls a marine chair. This chair was tried by Mr. Maskelyne, in his voyage to Barbadoes, who found it totally impracticable to derive any advantage from the use of it: and indeed, considering the great power requisite in a telescope for making these observations well, and the violence, as well as irregularities of the motion of a ship, there is reason to fear that the complete management of a telescope on ship board will always remain among the desiderata in this part of nautical science. Since all methods which depend on the phenomena of the heavens have also this other defect, that they cannot be observed at all times; the improvement of time-keepers is an object of very great importance.

Mr. Whiston and Mr. Ditton have proposed a method of determining the *longitude*, by the flash and report of great guns. Sounds, it is known, move pretty equably in all their stages, whatever the sonorous body be that occasions them, or whatever the medium that conveys them. If, then, a mortar, or great gun, be exploded, at a place whose *longitude* is known, the difference between the time wherein the flash (which moves, as it were instantaneously) is seen, and the sound, which moves at the rate of a mile in four seconds, is heard, will give the distance of those places from each other: whence if their latitudes be known, the difference of *longitude* will be likewise known.

Again, if the hour and minute of the explosion be known (for the place where it is made), by observing the hour and minute from the sun or stars, at the place whose *longitude* is required; the difference between those times will give the *difference of longitude*.

Again, if the said mortar be loaded with an iron shell, full of combustible matter, and pointed perpendicularly, it will carry the same a mile high, which will be seen near a hundred miles: if therefore, neither the sound shall be heard, nor the flash seen, the distance of any remote place from the place of the mortar, may be determined from the altitude of the shell above the horizon of the place unknown: and the distance and latitudes known, the *longitude* is easily found. According to this scheme, it was proposed to have such mortars fixed at proper distances, and at known stations, on all the frequented coasts, islands, capes, &c and to be exploded at certain hours, for the observation of mariners.

This method, though good in the theory, yet is found useless in the practice; as being extremely troublesome, and yet precarious. It supposes that sounds may be heard forty, fifty, or sixty miles; of which, it is true, we have instances, but they are very rare; and, ordinarily, the report of a cannon is not heard above half so far, and sometimes much less. It supposes, again, sound to move always with equal velocity; whereas, in fact, its velocity is increased or diminished as it moves with or against the wind. It supposes, again, the strength of powder uniform; and that the same quantity carries the same range; the contrary whereof is known to every gunner. We say nothing of thick cloudy nights, when no lights can be seen; nor of stormy nights, when no sound can be heard; even at inconsiderable distances.

We have another method of finding the *longitude*, proposed by the same Mr. Whiston, *viz.* by the inclinatory, or DIPPING-*needle*.

LONGITUDE, *angle of*. See ANGLE.

LONGITUDE, *argument of*. See ARGUMENT.

LONGITUDE, *circles of*. See CIRCLE.

LONGITUDE, *degrees of*. See DEGREE.

LONGITUDE, *parallax of*. See PARALLAX.

LONGITUDE *refraction of*. See REFRACTION.

LONGITUDE *of motion*, is used by Dr. Wallis for the measure of motion, estimated according to the line of direction; on which principle, *longitude* of motion is the distance, or length, which the centre of any moving body runs through, as it moves on in a right line.

The same author calls the measure of any motion, estimated according to the line of direction of the vis motrix, the *altitude* of it.

Bellini also uses the terms *longitude* and *altitude* in the same sense, in many places of his writings, which an ordinary reader finds hard to understand, for want of this interpretation.

interpretation." By *altitudo* alſo in his nineteenth propoſition *de fabrikâ*, he means the thickneſs of the viſcid matter in the blood-veſſels; or the greateſt length a viſcid particle is extended into, from the ſide of a canal to its axis.

LONGITUDINAL, in *Anatomy*, is uſed to ſignify ſome part, or member, extended in length, or poſited lengthwiſe.

The membranes which compoſe the veſſels, are woven out of two kinds of fibres, the one *longitudinal*, the other *circular*, cutting the *longitudinal* at right angles.

The *longitudinal* fibres are tendinous and elaſtic; the *circular*, muſculous, and motrices, like ſphincters.

LONGUS, LONG, an epithet given by *Anatomiſts*, to a great number of muſcles, hereby contradiſtinguiſhed from BREVIS.

The ſecond extenſor of the carpus is called *longus*, in compariſon of the third extenſor, which is called *brevis*, *ſhort*. The *longus* has its origin in the bottom of the humerus, and, lying along the radius, paſſes underneath the ligamentum annulare, and is inſerted into the carpus.

The ſecond of the flexors of the neck is alſo called the *longus* or *longus colli*, and ſometimes *rectus*. It has its origin in the lateral part of the body of the four upper vertebræ of the back; and is inſerted into the body of the four vertebræ of the neck, and ſometimes into the occiput: this, in conjunction with the ſcalenum, bends the neck.

The third of the ſix muſcles of the elbow, or arm, which is the firſt of its extenſors, is alſo called *longus*, as being the longeſt of the extenſors. It has its origin on the upper ſide of the omoplate, near the neck, and deſcending by the hind part of the arm, is inſerted into the olecranum by a ſtrong aponeuroſis, which is common to it, and the ſecond and third extenſor of the arm.

The ſecond muſcle of the thumb, which is the firſt of its extenſors, is alſo called *longus*, as being longer than another extenſor of the ſame thumb, called *brevis*. The *longus* proceeds from the upper and external part of the bone of the elbow; and, riſing over the radius, is inſerted, by a forked tendon, into the ſecond bone of the thumb, which it extends. One of the four muſcles of the radius is alſo called the *longus*: this is the firſt of the two ſupinators, and has its origin three or four fingers breadth above the outer apophyſis of the humerus, whence running along the radius, it is inſerted into the inner parts of its lower apophyſis. It is called *longus* with regard to the other ſupinator, which is called *brevis*. Theſe two muſcles ſerve to turn the radius, ſo that the palm of the hand looks upward; which makes the ſupination.

The firſt of the abductors of the leg is alſo called the *longus*, or *longus tibiæ*; and bears this title more juſtly than any of the others, as being the longeſt muſcle in the whole body. It is alſo denominated *fascialis*, on account of its bearing ſome reſemblance to a *faſcia*, ſwathe; and *ſartorius*, or taylor's muſcle, becauſe it ſerves to bend the legs inward, as the taylors uſe to have them when at work. See *Tab. Anat. Muſcl.* fig. 1 n. 40. fig. 2 n. 38.

LONGUS *colli*, is a muſcle, which, with others, extends the cubitus. It ariſes from the inferior coſta of the ſcapula nigh its neck; and, paſſing between the two round muſcles, deſcends on the back ſide of the humerus; where it joins with the brevis, and brachiæus externus.

LONICERA. *See Upright* HONEYSUCKLE.

LOOF, or, as it is uſually pronounced, LUFF, a term uſed in conding of a ſhip. Thus,

LOOF *up*, is to bid the ſteerſman keep nearer to the wind.

LOOF *into a harbour*, is to ſail into it cloſe by the wind.

LOOF, *in ſpring-tides*, or *luff*, is when a ſhip that was going large before the wind, is brought cloſe by the wind.

When a ſhip ſails on a wind, that is, on a quarter-wind, they ſay to the ſteerſman, *keep your luff! veer as more! keep her to! touch the wind! have a care of the lee-latch!* All which words ſignify much the ſame thing, and bid the man at the helm to keep the ſhip near the wind.

LOOF *of a ſhip*, denotes the after-part of a ſhip's bow; or that part of her ſide forward where the planks begin to be incurvated into an arch, as they approach the ſtem. Hence, the guns which lie here are called *loof-pieces*.

LOOF-*lock*, in a ſhip, a tackle with two hooks to it, one of which is to hitch into the crengle of the main and fore-ſail, and the other is to hitch into a certain ſtrap, which is ſpliced into the cheſs-tree, and ſo down the ſail. Its uſe is to ſuccour the tackles in a large ſail, that all the ſtreſs may not bear upon the tack. Sometimes alſo it is uſed when the tack is to be ſeized the furer.

LOOF-*tackle*, or LUFF-*tackle*, in a *Ship*, a large *tackle*, larger than the jigger-tackle, but ſmaller than thoſe which hoiſt the heavier materials into and out of the veſſel, ſuch as the main and fore-tackles, the ſtay and quarter-tackles, &c. ſerving to lift all the ſmall weights in or out of the ſhip, and otherwiſe variouſly employed as occaſion requires.

LOOK-OUT, in *Sea Language*, denotes a watchful attention to ſome important object, or event, which is expected to ariſe from the preſent ſituation of a ſhip, &c. It is principally uſed when there is a probability of danger from the real or ſuppoſed proximity of land, rocks, enemies, &c. There is always a *look-out* kept on a ſhip's forecaſtle at ſea, to watch for any dangerous objects lying near her track; the mate of the watch accordingly calls often from the quarter-deck, *look-out afore there!* to the perſons appointed to this ſervice. Falconer.

LOOKING-*glaſs*, a plain glaſs ſpeculum, or mirror, which, being impervious to the light, reflects its rays, and ſo exhibits the images of objects placed before it.

The theory of *looking-glaſſes*, and the laws whereby they give the appearance of bodies, ſee under MIRROR.

LOOKING-*glaſſes, the manner of grinding and preparing*, is as follows:—A plate of glaſs is fixed to a horizontal table, and to another leſſer table is fixed another plate, over the hind part of which is added a box loaded with ſtones, and other weights. Over the firſt plate is ſprinkled fine ſand and water, in a ſufficient quantity for the grinding, and the ſecond or leſs plate is laid on it, and thus worked this way and that way, till each has planed the other's ſurface. As they begin to grow ſmoother, finer ſand is uſed, and at laſt powder of emalt. Being thus fitted for poliſhing, a wooden parallelopiped, lined with Tripoli earth, or burnt tin, tempered with water, is laid on the plate, and worked to and again, till the glaſs hath got a perfect politure.

It is found extremely difficult to bring a glaſs to an exact planeneſs. Hevelius judges more art required to bring glaſs to a perfect plane than to a ſphere. For poliſhing large plates of glaſs, they have a machine for the purpoſe. See GLASS.

The plates being poliſhed, a thin blotting paper is ſpread on a table or marble ſlab, and ſprinkled with fine powdered chalk; and this done, over the paper is laid a thin lamina or leaf of tin, on which is poured mercury, which is to be equally diſtributed over the leaf, with a hare's foot or cotton. Over the leaf is laid a very thin ſmooth paper, of which the kind called ſan-paper is beſt, and over that the glaſs-plate. With the left hand the glaſs-plate is preſſed down, and with the right the paper is gently drawn out; which done, the plate is covered with a thicker paper, and loaden with a greater weight, that the ſuperfluous mercury may be driven out, and the tin adhere more cloſely to the glaſs. When it is dried, the weight is removed, and the *looking-glaſs* is complete.

Some uſe an ounce of mercury with half an ounce of marcaſite or biſmuth, melted by the fire; and left the mercury evaporate in ſmoke, pour it into cold water; and when cold, ſqueeze it through a cloth or leather. Some alſo add a quarter of an ounce of lead and tin to the marcaſite, that the glaſs may dry the ſooner. See FOLIATING.

LOOKING-*glaſs*, *Venus's*, in *Botany*. See CAMPANULA.

LOOL, in *Metallurgy*, a veſſel made to receive the waſhings of ores of metals. The heavier or more metalline part of the ores remain in the trough in which they are waſhed; the lighter, and more earthy, run off with the water, but ſettle in the *lool*.

LOOM, the weaver's frame; a machine whereby ſeveral diſtinct threads are woven into one piece.

Looms are of various ſtructures, accommodated to the various kinds of materials to be woven, and the various manner of weaving them; viz. for woollens, ſilks, linens, cottons, cloths of gold; and other works, as tapeſtry, ribbands, ſtockings, &c. divers of which will be found under their proper heads. See WEAVING.

The weaver's *loom*-engine, otherwiſe called the Dutch *loom*-engine, was brought into uſe from Holland to London, in or about the year 1676.

LOOM, *heir*, in *Law*. See HEIR-*Loom*.

LOOM, at *Sea*. If a ſhip appear big, when ſeen at a diſtance, they ſay the *loom*, or appears a great ſail: the term is alſo uſed to denote the indiſtinct appearance of any other diſtant objects.

LOOM-*gale*, at *Sea*, a gentle, eaſy gale of wind, in which a ſhip can carry her top-ſails *a-trip*.

LOON, in *Ornithology*, a name given to the *columbus major*, or great diver; and alſo to the *columbus minor*. See *Tropic*-CREEK and DOB-CHICK.

LOOP, in the *Iron Works*, is a part of a ſow or block of caſt iron broken or melted off from the reſt, and prepared for the forge or hammer. The uſual method is, to break off the *loop* of about three quarters of a hundred weight. This *loop* they take up with their ſhingling-tongs, and beat it with iron hedges upon an iron-plate near the fire, that ſo it may not fall to pieces, but be in a condition to be carried under the hammer. It is then placed under the hammer, and a little water being drawn to make the hammer move but ſoftly, it is beat very gently, and by

this means the dross and foulness are forced off, and after this they draw more and more water by degrees, and beat it more and more till they bring it to a four-square mass, of about two feet long, which they call a bloom.

LOOP-*Holes*, in the *Sea-language*, are holes made in the coamings of the hatches of a ship, to fire muskets through in a close fight.

LOOPING, in *Metallurgy*, a word used by the miners of some counties of England, to express the running together of the matter of an ore into a mass, in the roasting, or first burning, intended only to calcine it so far as to make it fit for powdering. This accident, which gives the miners some trouble, is generally owing to the continuing the fire too long in this process.

To LOOSE, in *Sea-language*, is to unfurl or call *loose* any sail, in order to be set or dried, after rainy weather.

LOOSE-*strife*, *Lysimachia*, in *Botany*, a genus of the *pentandria monogynia* class, the characters of which are these: the empalement of the flower is permanent, and cut into five acute segments that are erect; the flower is of one petal, cut into five oblong oval segments to the bottom, which spread open flat; it hath five awl-shaped stamina about half the length of the petal, terminated by acute-pointed summits; in the center is situated a roundish germen, supporting a slender style of the length of the stamina, crowned by an obtuse stigma; the germen afterwards turns to a globular capsule, with one cell opening with ten valves, and filled with small angular seeds. Miller enumerates ten, and Linnæus eleven species. See MONEY-*wort*.

Pliaded LOOSE-*strife*, in *Botany*. See WILLOW-*herb*.

Purple and *spiked* LOOSE-*strife*, *hyssopus*, in *Botany*, a genus of the *dodecandria monogynia* class, the characters are, that the flower hath a cylindrical striated empalement of one leaf, indented at the brim in twelve parts, which are alternately smaller; it has six oblong blunt petals, inserted in the indentures of the empalement, and ten slender stamina of the length of the empalement, the upper being shorter than the lower, terminated by single rising summits; in the center is situated an oblong germen, which turns to an oblong acute capsule, with two cells filled with small seeds. Miller reckons ten and Linnæus nine species.

Virginian LOOSE-*strife*. See GAURA.

LOOSE *Style*. See STYLE.

LOOSENED. See HOOF-*loosened*.

LOPHIA, in *Anatomy*, a term for the upper part of the *cervix*, or back part of the human neck.

LOPHIUS, in *Ichthyology*, a genus of the *amphibia nantes* in the Linnæan system; having solitary spiracles near the branchiæ; many small teeth, pectoral fins, incident in the branchiæ; and only three branchiæ. The species are the GUACUCIA and RANA *piscatrix*.

LOPPA, a word used by the chemical writers, to express the metallic mass, which results from a crementatory calcination, either with or without regulus.

LOPPING, among *Gardeners*, the cutting in a proper and artful manner the branches of trees, so as to make them grow more beautiful or more durable.

It is observable, that most old trees are hollow within, and this is in general owing to their wrong management, the tops being suffered to grow too large before they are lopped. This is a very common error in regard to the ash, elm, hornbeam, &c. and is owing to peoples persuading themselves, that by this means they shall have more great woods; but they do not consider, that the cutting off large tops destroys or decays the tree, so that it decays more in the body than it grows in the head. And though the hornbeams and elm will bear large tops when the outside is little more than a shell, yet this is not at all the case with the ash, which should therefore always be cut down as soon as it begins to decay. See HOLLOWNESS *of Trees*.

The *lopping* of young trees, that is of such as are ten or twelve years old, will preserve them much longer, and will occasion the shoots to grow more into the wood in one year, than they do in old tops in two or three. The taking off of large boughs in a careless manner destroys many a tree; they should therefore always be lopped close and smooth, and not parallel to the horizon, and the wound covered with some loam to keep it from rotting, and preventing the wet from entering and getting into the body of the tree.

All sorts of resinous trees, or such as abound with a milky juice, should be lopped but very sparingly, for they are very subject to decay when cut. The best season for the *lopping* these is the end of August, when they will not bleed very much, and the wounds will heal before the hard weather. Miller.

Whatever shape a tree is intended to be of, it must be thrown into it by *lopping* while young, for the branches being then small, full of juice, heal easily and never endanger the tree. When a tree is intended for timber it must be left to grow to its own height, and its top is never to be cut off on any account. Those trees which have large pithy, as the ash, elm, willow, poplar, and the like, must never have their heads cut off, if intended to stand long, for the wet gets into the soft part of the tree, and begins to hollow, and rot it where cut off, and soon spreads to the very root, so that the whole is but a shell or case of a tree. If a tree grow top heavy, and be in danger of breaking down, then some think it necessary to take off the top to preserve it; but this may be much better done only by thinning the top, that is cutting off the small branches that grow from the main boughs of the head, and leaving them bare, so as to let the wind have a free passage through them. This is a very good practice for young trees, which are intended to be spreading ones; and if they are intended to be tall and slender ones, the best method to be taken with them, while young, is rubbing off the buds as fast as they appear in the spring, and taking off the side-shoots as they grow, leaving only here and there one; when any new shoots break out, some of them may be saved, and the others cut off in their place, always observing to cut off the largest, and leave the youngest; the whole intent being to leave some check there for the sap, to prevent its all running up to the head, which would endanger the breaking of the body in some weak place. When the trunk learns strong and robust, the shoots of these roots need be left in the great care. In this case, it is to be employed about the head. The leading shaft or branch, must be carried on all the way straight and single, and not suffered to fork or split till it come to the head, and the quantity of boughs left there must be such as will not leave the whole top-heavy. When the tree is grown to its proper height, the head is to be suffered to break out in its natural way, and the side branches are to be kept cut off as they shoot, or at any proper distances of time.

If the side-boughs are found still breaking out, and the top is able to sustain itself, the boughs that put out in spring should be lopped very close in summer, a little after Midsummer; this will cause the bark to shoot over them, and they will not be liable to grow again. This is the only method of making a tree grow with a fine straight and handsome body.

The generality of the world are against pruning timber-trees at all, and where they naturally grow straight and regular, it is much better let alone. But all the common faults in shape may be regulated by this *lopping* them while young, and it can be attended with no ill consequence to the timber; for the cut not lying near the timber pith, cannot affect it when grown up, and squared in the working for beams or other uses, or to be quartered; for all the defects, occasioned by such wounds, are in the superficial parts, and all the four quarters are perfectly sound within.

As to the large forest-trees they should not be lopped at all, except in cases of great necessity, and then the large boughs must not be cut, but only the side-branches, and even these must be cut off close, that the bark may soon cover the wound, and yet a little slanting, that the water may run off, and not lodge upon the cut part.

If there is a necessity of cutting off a large bough, as by its being broken or cankered, let it be cut off slanting at about four feet distance from the body of the tree, and that if possible near some place where there is a young shoot from it, which may receive the sap and grow up in its place. No stump must be left standing out farther than this, because they are wounded parts which never can heal, and which will always be letting in the water, and will serve as pipes to convey that water to the heart of the body of the tree, and by degrees will utterly spoil it. All that grow upright, whether they be large or small branches, must in cutting be taken off slanting, never evenly for the same reason; those boughs that bear from the head are to be cut with the slope on the lower side, and on any occasion that great wounds are given to a tree, they should be covered with a mixture of clay and horse-dung, which will make them heal much sooner than they otherwise would do. Mortimer. See SUMMER-*Trees*.

LORANTHUS, in *Botany*, a genus of the *decandria monogynia* class. Its characters are these: the flower is tubulous, and cut into six narrow segments, almost to the bottom, which are reflexed; the germen is situated below the empalement, and becomes a berry containing one seed. Linnæus enumerates nine species.

LORARII, among *the Romans*, officers whose business it was, with whips and scourges, to compel the gladiators to engage. The *lorarii* also punished slaves who disobeyed their masters.

LORD, a title of honour attributed to those who are no-

ble, either by birth, or creation; and vested with the dignity of a baron.

The word is of Saxon origin, and primarily denotes a bread-giver, alluding to the hospitality of our ancient nobles: it is formed, according to Camden, from *hlaford*, afterwards written *lisford*, a compound of *hlaf*, *bread*, and *ford*, *to supply, afford*.

In this sense, *lord* amounts to the same with *peer* of the realm, *lord* of parliament.

LORD is also applied to those so called by the courtesy of England; as all sons of a duke or marquis, and the eldest son of an earl.

LORD is also an appellation given to divers persons honourable by office; as *lord* chief justice, *lord* chancellor, *lord* of the treasury, admiralty, *&c.*

LORD is also a title sometimes given to an inferior person who has a fee, and consequently the homage of tenants within his manor.

The by his tenants he is called *lord*, and in some places, for distinction-sake, *landlord*.

It is in this last signification that the word *lord* is principally used in our law-books; where it is divided into *lord paramount*, and *lord mesne*.

LORD *mesne*, is he that is owner of a manor, and by virtue thereof hath tenants holding of him in fee, and by copy of court-roll; and yet holds himself of a superior *lord* called *lord paramount*.

We also read of *every lord*, and *every tenant*.

LORD *in gross*, he who is *lord*, not by reason of any manor, as the king in respect of his crown, *&c.*

Very LORD, is he who is immediate *lord* to his tenant; and *very tenant*, he who holds immediately of that *lord*.

So that where there is *lord* paramount, *lord* mesne, and tenant; the *lord* paramount is not very *lord* to the tenant.

LORD *high-admiral* of England, is one of the great officers of the crown, whose trust and honour is so great, that it was formerly seldom given, except to some of the king's youngest sons, or near kinsmen.

To him is, by the king, intrusted the management of all maritime affairs, as well in respect to jurisdiction as protection; with the government of the British navy; and a power to decide all controversies and causes maritime, as well civil as criminal; such as happen either on our coasts, or beyond sea, among his majesty's subjects.

To him also belong such wrecks and prizes, as are called LAGON, JETSON, and FLOTSON; that is, goods lying in the sea floating, or cast on shore, excepting in such royalties as are granted to other *lords* of manors, *&c.* with all great fishes, called *royal* FISH, except whales and sturgeon; a share of prizes in time of war, and the goods of pirates and felons condemned.

The *lord high admiral* has under him many officers of high and low condition, some at sea, others at land; some of a military, others of a civil capacity; some judicial, others ministerial. See ADMIRAL.

This great office is now usually executed by seven commissioners, who are styled *lords of the admiralty*: one is called the first *lord*, with a salary of 3000*l.* a year, the others have 1000*l.* a year each. Under these there are a secretary and deputy-secretary and several inferior clerks.

In this court, called the *court of admiralty*, all proceeds issue in his name, not the king's, as they do in all other courts; to that the dominion and jurisdiction of the sea may justly be styled another commonwealth, or kingdom apart, and the *lord high admiral*, the viceroy of the maritime kingdom.

He hath under him a lieutenant, or deputy, who is judge of the admiralty, commonly a doctor of the civil law. See COURT *of Admiralty*.

LORD *privy-seal*, has his office by patent: before the fifteenth of Henry VIII. he was generally, an ecclesiastic; since which, the office has been usually conferred on temporal peers, above the degree of barons.

The *lord privy-seal*, receiving a warrant from the signet-office, issues the privy-seal, which is an authority to the lord chancellor to pass the great seal, where the nature of the grant requires the SEAL.—But privy-seals for money begin in the treasury, from whence the first warrant issues, countersigned by the lord treasurer.—On the *lord privy-seal* are attendant four clerks, who have two deputies to act for them.

LORD *steward of the king's household*, is the principal officer for the civil government of the king's servants below-stairs; over the officers of which he has jurisdiction. See HOUSEHOLD.

He is constituted by the delivery of the white staff, which is esteemed his commission.—By virtue of his office, without any other commission, he judges of all offences committed within the court, or the verge thereof; and gives judgment according to their several deserts.

At the death of the sovereign he breaks his staff over the grave in which the royal corpse is deposited, and thereby discharges all the officers under his power.

LORD *advocate*. See ADVOCATE.

LORD *high-treasurer*. See TREASURER.

LORD *chamberlain of the household*. } See CHAMBERLAIN.
LORD *great-chamberlain of England*. }

LORD *high-chancellor of England*. See CHANCELLOR.

LORDS *of the bed-chamber* are fourteen in number under the *Lord* Chamberlain. See BED-CHAMBER.

LORDS *of session*. See SESSION.

LORDS, *house of*. See PEER.

LORDS *of the treasury*. See TREASURY.

LORDS *lieutenants of counties*, are officers of great distinction, appointed by the king for the managing the standing militia of the county, and all military matters therein. They are supposed to have been introduced about the reign of king Henry VIII. for they are mentioned as known officers in the statute 4 and 5 Ph. and M. c. 3. though they had not been then long in use; for Camden speaks of them, in the time of queen Elizabeth, as extraordinary magistrates constituted only in times of difficulty and danger.

They are generally of the principal nobility, and of the best interest in the county: they are to form the militia in case of a rebellion, *&c.* and march at the head of them, as the king shall direct.

They have the power of commissioning colonels, majors, captains, and subaltern officers; also to present the king with the names of deputy-lieutenants, who are to be selected from the best gentry, in the county, and act in the absence of the *lords-lieutenants*.

Subservient to the *lords-lieutenants*, and deputy-lieutenants, are the justices of peace; who, according to the order they receive from them, are to issue out warrants to the high and petty-constables, *&c.* for military service, *&c.*

LORD'S *Day*. See SUNDAY.

LORDOSIS, of ὁρδὸς, *bent inwards*, in the *Medical Writings*, a name given to a distempered state of the spine, in which it is bent inwards, or toward the anterior parts. It is used in opposition to gibbous, or hump-backed.

LORICATION, or CRATING, in *Chemistry*, is the covering a glass or earthen vessel with a coat or crust of a matter able to resist the fire, to prevent its breaking in the performing an operation that requires great violence of fire.

When vessels are exposed to a fire too strong for their structure, or to the corrosive quality contained in them, or on the throwing on of fresh cold fuel into the fire where they stand, it frequently happens that they crack and burst; for the preventing of which, the operator has recourse to this method of *coating* or *lorication* his vessels. It is performed in the following manner: take a quantity of washed clay, with an admixture of pure sand, powder of calcined flints, or broken crucibles; and instead of pure water moisten it with fresh blood that has not yet been coagulated, diluted with twice or three times its quantity of water; make the clay with this into a thin paste, and work into it some cow's hair, or other hair not too long nor too fine, and a little powdered and sifted glass, if you have it at hand; smear over the vessel intended to be used with this paste, by means of a pencil, and let it to dry; when dry, besmear it again, and repeat the operation till the vessel have a crust of a third, or a quarter of an inch, at least, thick of this matter, and let it be thoroughly dry before it is used.

To keep blood in a proper state for this use, it must, when just let out from the animal, be well stirred about with a stick for some time, at least till it is quite cold; and being thus prepared, it will keep for some days without coagulating, and fit for use.

This composition, with an admixture of hole, worked into a paste with the whites of eggs, diluted with water, makes also the proper LUTE for closing the junctures of other chemical vessels, in the distilling strong spirits.

LORIMERS, one of the COMPANIES of London, that make bits for bridles, spurs, and such like small iron ware. They are mentioned Stat. 1 Rich. II. cap. 12.

The word seems derived from the Latin, *lorum*, a thong.

LORIPES, in *Zoology*, the name used by some authors for the HIMANTOPUS, a bird of the water-kind, remarkable for the length and weakness of its legs.

LORIS, in *Zoology*, a species of LEMUR in the Linnæan system, being the *lemur tardigradus* of Buffon, described by Buffon. Nat. Hist. vol. xxii. p. 277. *Tab.* III. *Quadrupeds*, N° 29. See MALACCO.

LORUS, a name by which some of the chemical writers have called mercury.

LOT

LOT in a legal ſenſe. See SCOT.

LOT, or LOTH, in *Mining*, is the thirteenth diſh, meaſure, or part of the miner's ore, which the bar-maſter takes up for the king, or the farmer.

LOTA, in *Zoology*, the name of a ſpecies of the *muſtela fluviatilis*, or RIVER-*ſtoat*, differing from the ordinary kind, in that it has no hairs or excreſcences on the upper jaw; the tail is flat, and like the point of a broad ſword, whereas that of the common kind is more rounded; and that it is covered with eaſily diſtinguiſhable ſcales.

LOTE-*tree*, in *Botany*. See NETTLE *tree*.

LOTION, LOTIO, popularly called *waſh*, denotes a form of medicine, made up of liquid matters, chiefly uſed for beautifying the ſkin, and cleanſing it from thoſe deformities which a diſtempered blood ſometimes throws on it, or rather, which are occaſioned by a preternatural ſecretion. For, generally ſpeaking, thoſe diſtempers of the ſkin, which are accounted ſigns of a foul blood, proceed from the natural ſalts thrown off by the cutaneous glands, which ought to be waſhed away through the kidneys; ſo that inſtead of ſweeteners, which are uſually preſcribed on thoſe occaſions, Dr. Quincy thinks the urinary diſcharge ſhould be promoted, or that of the ſkin reſtored by proper *lotions*, or ointments and frictions.

LOTION alſo denotes a remedy, conſiſting a medium between a fomentation and a bath.

There are refreſhing and ſomniferous *lotions* for feverith perſons, made of leaves, flowers, and roots boiled, wherewith the feet and hands of the patient are waſhed; and after waſhing, wrapped up in linen, ſteeped in the ſame decoction, till dry.

There are *lotions* alſo for the head and hair, made of the aſhes of vine-twigs.

LOTION *of the philoſophers*, in *Chemiſtry*, is a coboabation which nature makes of what is raiſed up, and afterwards falls back again to the bottom of the veſſel.

LOTION, in *Pharmacy*, denotes a preparation of medicines, by waſhing them in ſome liquid, either made very light, ſo as to take away only the dregs; or ſharp, ſo as to penetrate them, in order to clear them of ſome fait, or corroſive ſpirit, as is done to antimony, precipitates, magiſteries, &c. or intended to take away ſome foulneſs, or ill quality, or to communicate ſome good one.

LOTIO *ſaponacea*, the *ſapunaceous lotion*, the name of a form of medicine preſcribed in the late London Pharmacopœia, being properly ſoap in a liquid form. It is ordered to be made thus: take damaſk roſe-water, three quarters of a pint; oil of olives, a quarter of a pint; ley of tartar, half an ounce in meaſure: rub the ley and oil together till they are mixed, and then gradually add the water.

LOTOMETRA, in *Botany*, a name given by many of the antients to the *nymphæa Indica*, or *Ægyptiaca*, called alſo the *faba Ægyptiaca*, and originally the *nilufar*, an abbreviation of *nilufar*; *nufar* ſignifying a water lily, and the prefix *nil* expreſſing its growing particularly in the river Nile.

Neophytus tells us, that this *lotometra* has leaves of a middle form between thoſe of the common *nymphæa*, which are roundiſh, and thoſe of the *arum*, which are oblong and pointed, and are cordated at the baſe; and this is the very figure of the leaves of the *faba Ægyptiaca*, as we ſee it in all paintings, &c.

LOTTERY, a kind of game at hazard, wherein ſeveral lots of merchandize, or ſums of money, are depoſited as prizes, for the benefit of the fortunate.

The deſign of *lotteries*, and the manner of drawing them, are too well known among us to need a deſcription: they are very frequent in England and Holland, where they cannot be ſet on foot without the permiſſion of the magiſtrate.—In France too, there have been ſeveral *lotteries* in favour of their hoſpitals.

M. le Clerc has compoſed a treatiſe of *lotteries*, wherein is ſhewn what is laudable, and what blameable in them.—Gregorio Leti has alſo a book on the ſubject of *lotteries*. Father Meneſtrier has a treatiſe on the ſame, publiſhed in 1700, where he ſhews their origin, and uſe among the Romans. He diſtinguiſhes ſeveral kinds of *lotteries*, and takes occaſion to ſpeak of chances, and reſolves ſeveral caſes of conſcience relating thereto.

The firſt *lottery* in England of which we have any account, was drawn at the weſt door of St. Paul's cathedral, in the year 1569, and conſiſted of 40,000 lots, at ten ſhillings each lot; the prizes were plate; and the profits were to be applied towards repairing the havens of this kingdom. At this time there were only three *lottery* offices in London.

In 1612, king James, for the plantation of Engliſh colonies in Virginia, appointed a *lottery*, to be held at the weſt end of St. Paul's: the chief prize of which was 4000 crowns, in fair plate. But by 10 and 11 W. c. 17. all *lotteries* are declared to be public nuiſances, and all grants, patents and licences, for ſuch *lotteries*, to be againſt law. They are farther prohibited under penalties by 9 Ann. c. 6.

By the 8 Geo. I. c. 2. for ſuppreſſion of private *lotteries*, no perſon ſhall ſet up or keep any office, or ſales of houſes or lands, plate, goods, &c. for improvement of ſmall ſums of money, or expoſe to ſale any houſes or goods by way of *lottery*, lots, tickets, or numbers, or publiſh propoſals relating to the ſame, &c. on pain of forfeiting 500l. And adventurers in ſuch ſales ſhall forfeit double the ſum contributed. See 9 Geo. I. No perſon ſhall ſell the chance of any ticket in a public *lottery* for leſs than the whole time of drawing; nor any ſhares therein, or receive money on conſideration of repayment, if tickets prove unfortunate, on forfeiture of treble the ſum received: to be recovered in the courts of Weſtminſter, &c. Stat. 6 Geo. II.

See other ſtatutes relating to *lotteries* under the article GAMING. The act paſſed in 1778, for regulating the conduct of the *lottery* reſtrains any perſon from keeping an office for the ſale of tickets, ſhares, or chances, or for buying, ſelling, inſuring or regiſtering, without a licence; for which licence each office-keeper muſt pay 50l. to continue in force for one year, and the produce to be applied towards defraying the expences of the *lottery*. And no perſon is allowed to ſell any ſhare or chance leſs than a ſixteenth, on the penalty of 50l. All tickets divided into ſhares or chances are to be depoſited in an office, to be eſtabliſhed in London by the commiſſioners of the Treaſury, who are to appoint a perſon to conduct the buſineſs thereof; and all ſhares are to be ſtamped by the ſaid officer, who is to give a receipt, for every ticket depoſited with him. The numbers of all tickets ſo depoſited are to be entered in a book, with the names of the owners, and the number of ſhares into which they are divided; and two pence for each ſhare is to be paid to the officer on depoſiting ſuch tickets, who is therewith to pay all expences incident to the office. All tickets depoſited in the office are to remain there three days after the drawing. And any perſon keeping an office, or ſelling ſhares, or who ſhall publiſh any ſcheme for receiving moneys in conſideration of any intereſt to be granted in any ticket in the ſaid *lottery*, &c. without being in poſſeſſion of ſuch ticket, ſhall forfeit 500l. and ſuffer three months impriſonment. And no buſineſs is to be tranſacted at any of the offices after eight in the evening, except on the evening of the Saturday preceding the drawing. No perſon is to keep any office for the ſale of tickets, &c. in Oxford or Cambridge, on penalty of 20l. Before this regulating ſtatute took place, there were upwards of 400 *lottery* offices in and about London only; but the whole number afterwards, for all England, as appeared by the liſt publiſhed by authority, amounted to no more than 51.

The various calculations, relating to *lotteries*, depend on an acquaintance with the doctrine of chances, a ſummary of which the reader will find under the article of GAMING. Thus by Prob. II. under that article, it is eaſy to find how many tickets one muſt take in a *lottery* where of the number of blanks to the number of prizes as 39 to 1, in order to make it an equal chance for one or more prizes. Multiply 39 by 0.7, and the product 27.3 ſhews that the number of tickets for this purpoſe will be 27 or 28 at moſt. In a *lottery* likewiſe, whereof the number of blanks is to the number of prizes as 5 to 1, multiply 5 by 0.7, and the product 3.5 ſhews, that there is more than an equality of chance in four tickets for one or more prizes, but leſs than an equality in three. But if, in a *lottery* having the blanks to the prizes as 39 to 1, the whole number of tickets were only 40, the above proportion would be altered; for 20 tickets would be a ſufficient number for the juſt expectation of the ſingle prize; becauſe it is evident, that the prize may be as well among the tickets which are taken, as among thoſe that are left behind. Moreover, if the number of tickets were 80, and the ſame proportion of blanks to prizes preſerved, the proportion would ſtill be altered; for by the doctrine of combination it appears, that the probability of taking one prize, or both in 20 tickets would be but $\frac{1}{2}\frac{9}{0}$, and the probability of taking none would be $\frac{1}{2}\frac{7}{0}$, wherefore the odds againſt taking any prize would be as 177 to 130, or nearly as 9 to 7. By the ſame doctrine of combination it alſo appears, that 23 tickets would not be quite ſufficient for the expectation of a prize in this *lottery*; but that 24 would rather be too many: ſo that one might with advantage lay an even wager of taking a prize in 24 tickets.

If the proportion of 39 to 1 be oftener repeated, the number of tickets requiſite for the equal chance of a prize, will ſtill increaſe with that repetition; yet let the

proportion of 39 to 1 be repeated ever ſo many times, nay, an infinite number of times, the number of tickets requiſite for the equal chance of a prize would never exceed $\frac{1}{39}$ of 39, that is about 27 or 28. Wherefore, if the proportion of the blanks to the prizes be often repeated, as it uſually is in *lotteries*, the number of tickets requiſite for a prize will always be found by taking $\frac{1}{39}$ of the proportion of the blanks to the prizes.

Again, by Prob. IV. under GAMING, it may be found how many tickets muſt be taken, in a *lottery* whoſe number of blanks is to that of the prizes, as 39 to 1, in order to make it as probable that 2 or more benefits will be taken as not: multiply 39 by 1.678, and the product 65.4 will ſhew, that no leſs than 65 tickets will be requiſite to that effect.

Farther, by Prob. IX. under GAMING, we may find, in a *lottery* conſiſting of 40000 tickets, among which are three particular benefits, what is the probability that taking 8000 of them, one or more of the particular benefits ſhall be among them. Subſtitute 8000, 40000, 32000, 3, and 1 reſpectively for c, n, a, e, and p, in that problem; and the probability of taking preciſely one of the three particular benefits will appear to be $\frac{8000 \times 32000 \times 31999 \times 3}{40000 \times 39999 \times 39998} = \frac{48}{125}$ nearly. If $p=2$, the probability of taking preciſely 2 of the particular benefits will be $\frac{8000 \times 7999 \times 32000 \times 3}{40000 \times 39999 \times 39998} = \frac{12}{125}$ nearly. If $p=3$, the probability of taking all the 3 particular benefits, will be $\frac{8000 \times 7999 \times 7998}{40000 \times 39999 \times 39998} = \frac{1}{125}$. And the probability of taking one or more of the three particular benefits will be $\frac{48+12+1}{125} = \frac{61}{125}$ very nearly. Theſe three operations might have been contracted into one by inquiring the probability of not taking any of the three particular benefits, which will be found to be $\frac{32000 \times 31999 \times 31998}{40000 \times 39999 \times 39998} = \frac{64}{125}$ nearly, which being ſubtracted from unity, gives a remainder, $1 - \frac{64}{125} = \frac{61}{125}$, ſhewing the probability required; and therefore the odds againſt taking any of three particular benefits will be 64 to 61 nearly.

2. To find by the ſame problem how many tickets ought to be taken in a *lottery* conſiſting of 40000, among which are three particular benefits, to make it as probable that one or more of theſe three may be taken as not. Let the number of tickets requiſite to be taken be $= x$, and the probability of not taking any of the particular benefits will be $\frac{n-x}{n} \times \frac{n-x-1}{n-1} \times \frac{n-x-2}{n-2}$ but this probability is equal to $\frac{1}{2}$, ſince by hypotheſis, the probability of taking one or more of them is equal to $\frac{1}{2}$; whence we ſhall have the equation $\frac{n-x}{n} \times \frac{n-x-1}{n-1} \times \frac{n-x-2}{n-2} = \frac{1}{2}$, from the ſolution of which x will be found nearly equal to 8252. The terms of this equation, Mr. De Moivre obſerves, may be conſidered as being in geometric progreſſion; ſince the factors both of the numerator and denominator are few and in arithmetic progreſſion, and their difference very ſmall in reſpect of n: and, therefore, the cube of the middle term may be ſuppoſed equal to the product of the multiplication of theſe terms; whence will ariſe the equation, $\left(\frac{n-x-1}{n-1}\right)^3 = \frac{1}{2}$, or, neglecting unit both in the numerator and *denominator*, $\left(\frac{n-x}{n}\right)^3 = \frac{1}{2}$ and x, conſequently, $= n \times 1 - \sqrt[3]{\frac{1}{2}}$, or $n \times 1 - \frac{1}{2}\sqrt[3]{4}$: but $n = 40000$, and $1 - \frac{1}{2}\sqrt[3]{4} = 0.20634$; therefore $x = 8252$.

3. To determine accurately, in a *lottery* of 100000 tickets, whereof 90000 are blanks, and 10000 are benefits, what the odds are of taking or not taking a benefit, in any number of tickets aſſigned. Let the number be 6; and it will appear, by the above cited problem, that the number of chances for taking no prize in 6 tickets, making $a=100000$, $b=90000$, $c=b$, $p=6$, $n=100000$, will be $\frac{90000}{1} \times \frac{89999}{2} \times \frac{89998}{3} \times \frac{89997}{4} \times \frac{89996}{5} \times \frac{89995}{6}$ and that the whole number of chances will be $\frac{100000}{1} \times \frac{99999}{2} \times \frac{99998}{3} \times \frac{99997}{4} \times \frac{99996}{5} \times \frac{99995}{6}$ then dividing the firſt number of chances by the ſecond, by means of LOGARITHMS, the quotient will be 0.53143, the probability required: this decimal fraction being ſubtracted from unity, the remainder 0.46857 ſhews the probability of taking one prize or more in 6 tickets; wherefore the odds againſt taking any prize in 6 tickets will be 53143 to 46857. If the number of tickets be 7, then carrying each number of chances above written one ſtep farther, we ſhall find that the probability of taking no prize in 7 tickets is 0.47828, which ſubtracted from unit leaves a remainder 0.52172, which ſhews the odds of taking one prize or more in 7 tickets to be 52172 to 47828.

4. By the ſame problem, to find the value of the chance of a prize, ſuppoſing each ticket to be 10*l.* and that after the *lottery* is drawn, 7*l.* 10*s.* be returned to the blanks. There being 90000 blanks, to each of which is returned 7*l.* 10*s.* the total value of the blanks is 675000*l.* and conſequently, the total value of the benefits is 325000*l.* which being divided by 10000, the number of benefits, gives a quotient 32*l.* 10*s.* and, therefore, one might for the ſum of 32*l.* 10*s.* be intitled to have a benefit certain, taken at random out of the whole number of benefits: the purchaſer of a chance has, therefore, one chance in ten for the ſum of 3*l.* 10*s.* and nine chances in ten for loſing his money, from whence it follows, that the value of his chance is the 10th part of 32*l.* 10*s.* *i. e.* 3*l.* 5*s.* And conſequently the purchaſer of a chance, by giving the ſeller 3*l.* 5*s.* is intitled to the chance of a benefit, and ought not to return any thing to the ſeller, although he ſhould have a prize; for the ſeller having 3*l.* 5*s.* ſure, and nine chances in ten for 7*l.* 10*s.* the value of which chance is 6*l.* 15*s.* it follows that he has his 10*l.* 5*s.*

In the ſame kind of *lottery*, let A engage to furniſh B with a chance, on condition that whenever the ticket on which the chance depends, ſhall happen to be drawn, whether it proves a blank or prize, A ſhall furniſh B with a new chance, and ſo on, as often as there is occaſion, till the whole *lottery* is drawn; it is propoſed to find what conſideration B ought to give A before the *lottery* begins to be drawn, for the chance or chances of one or more prizes, admitting that the *lottery* will be 40 days in drawing.

Let the abſolute value of a chance, or 3*l.* 5*s.* be called s. Firſt A who is the ſeller ought to conſider, that on the firſt day he furniſhes neceſſarily a chance whoſe value is s.

2dly, That on the ſecond day, he does not neceſſarily furniſh a chance, but conditionally, *viz.* if it ſo happen that the ticket on which the chance depends, ſhould be drawn on the firſt day; but the probability of its being drawn on the firſt day is $\frac{1}{40}$, and therefore, he ought to take $\frac{1}{40}s$ for the conſideration of the ſecond day.

3dly, That in the ſame manner he does not neceſſarily furniſh a change on the third day, but conditionally, in caſe the only ticket depending (for there can be but one) ſhould happen to be drawn on the ſecond day; of which the probability being $\frac{1}{39}$, by reaſon of the remaining 39 days from the ſecond incluſive to the laſt, it follows, that the value of that chance is $\frac{1}{39}s$.

4thly, And for the ſame reaſon the value of the next is $\frac{1}{38}s$, &c. the purchaſer ought, therefore, to give the ſeller $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c. + \frac{1}{39} + \frac{1}{40} \times s$, or $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c. + \frac{1}{38} \times s$. The ſum of theſe 40 terms, being 4.2785 nearly, multiplied by s or 3*l.* 5*s.* will give a product 13*l.* 9*s.* ſhewing that the purchaſer ought to give the ſeller about 13*l.* 18*s.*

From what has been ſaid it appears, that the value of the chance 1 for one ſingle day that ſhall be fixed upon is the value of that chance divided by the number of days intercepted between that day inclusive and the number of days remaining to the end of the *lottery*: which, however, muſt be underſtood with this reſtriction, that the day fixed upon muſt be choſen before the *lottery* begins; or if it be done on any other day, the ſtate of the *lottery* muſt be known, and a new calculation made accordingly for the value of s. De Moivre's Doctrine of Chances, 1756.

LOTTERY is alſo the name of a well known game at cards.

LOTUS, in *Botany*; ſee *Bird's Foot* TREFOIL.

LOTUS *Africana*. See *Indian date* PLUM.

Bladder LOTUS, a name ſometimes given to a ſpecies of *colutea*, or *anthyllis*. See LADY's *Finger*.

LOTUS, *coryalamus*, a name given by the ancient Greeks to an Egyptian plant according to ſome, and according to others, to a rare plant, found only in few places, and only met with by accident, by the people who made long and uncommon voyages. The whole account given of it, by the earlieſt writers, is no more than

that it was of a very sweet and pleasant taste. Mysepsus uses the term frequently, and his interpreters understand him to mean the *cassia fistula* by it. But we have accounts from Homer, that the followers of Ulysses were detained by eating the *lotus glycycalamus*; and it is not at all probable, that the *cassia fistula* could be the thing meant by the word in this place; neither will the words of the author allow it to be any thing of this kind. The *cassia fistula* is the fruit of a tree; but this *glycycalamus* we find in Homer himself was an herbaceous plant. Quintilian calls it expressly a kind of grass, *gramen*; and from the other accounts of its growing in form of reeds, and in wet places; it seems very probable, that it was the sugar-cane that they called by this name. See *Indian Date* PLUM.

LOVAGE, *ligusticum*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: it has an umbellated flower, the general umbel composed of several smaller; this umbel has an involucrum of seven unequal leaves; the perianthium of the flower is indented in five parts, and the flower has five equal petals, which are inflexed at their points, and five hairy stamina; the germen, which is situated under the flower, turns to an oblong fruit, divided into two parts; it is angular and channelled, containing two oblong smooth seeds. Miller reckons five and Linnæus six species.

The root, leaves, and seeds of the common *lovage* with many leaves, whose lobes are cut toward the tops, are of the aromatic kind: they warm and comfort the stomach, expel wind, and provoke urine. They have been supposed particularly useful in female disorders.

LOVE, in *Ethics*, is one of the primitive passions; and may be generally defined to be the gravitation or tendency of the soul towards good. If this affection be conceived separate from any alteration in the body, it is called intellectual or rational *love*; if it be attended with an agitation of blood and spirits, it is called sensitive or passionate *love*. It is observed by moral writers, that those passions in which *love* predominates are more agreeable to the original intention of nature than those which are ranged under hatred; because they are found to have a more friendly influence upon the body, and tend, within proper bounds, to the preservation and happiness of life, which the others do not. See Cumberland de Leg. Nat. c. 2. § 18. *Love* regarding its object as absent, begets desire; as present, either immediately or in prospect, joy and hope. *Love* of desire, abstractedly considered, is a simple tendency towards good; when considered as wishing the good desired to some being or other, it is called BENEVOLENCE, and SELF-*love*. See PLEASURE, and PAIN.

LOVE, *family of*. See FAMILY.

LOVE, *Platonic*. See PLATONIC.

LOVE-*apple* is the English name for the fruit of the LYCOPERSICON, a plant cultivated in gardens with us, for the singularity of its appearance. The Portuguese call it *tomato*, and eat the fruit, either raw or stewed; as do also the Jew families in England.

LOVE-*grass*; see GRASS.

LOVE *in a mist*; see PASSION *Flower*.

LOVE *lies a bleeding*. See AMARANTH.

Tree of LOVE. See JUDAS *Tree*.

LOUIS, LEWIS, LOUIS D'OR, or LEWIDORE, a French coin, first struck in 1641, under the reign of Louis XIII. and which has now a considerable currency.

Louis d'ors, at first, were valued at ten livres, afterwards at eleven, and at length at twelve and fourteen. In the latter end of the reign of Louis XIV. they were risen to twenty, and in the beginning of that of Louis XV. to thirty and thirty-six, nay, forty and upwards; with this difference, however, that in the last coinings the weight was augmented in some proportion to the price, which, in the former reign, was never regarded.

On one side of the coin is the king's head seen, with his name; and on the other, a cross composed of eight L's cantoned with crowns. The legend is, *Christus regnat, vincit, imperat*.—The reverse has been frequently changed; at present, it bears a hand of justice crossed in a saltier, with a sceptre.

There are also *white* LOUISES, or LOUIS *d'argent*, some of 120, others of 60 sols a-piece, called also *ecus*; and among us, *French crowns, half-crowns*, &c.

On the one side of these is the king's head, and on the other the French arms, with this legend, *Sit nomen Domini benedictum*.

Knights of S. LOUIS, is the name of a military order, instituted by Louis XIV. in 1693.

Their collar is of a flame-colour, and passes from left to right. The king is their grand-master. There are in it eight great crosses, and twenty-four commanders. The number of knights is not limited. At the time of their institution, the king charged his revenue with a fund of three hundred thousand livres, for the pensions of the commanders and knights.

LOUS, AOS, in *Chronology*, the Macedonian name for the Athenian month HECATOMBÆON, which was the first of their year, and answered to the latter part of our June and the beginning of July.

LOUSE, *pediculus*, in *Zoology*, a genus of insects of the *aptera* order, the body of which is lobated at the sides; the abdomen depressed; the legs are six, serving only for walking; the eyes are two, and are simple; the mouth is capable of putting out a small sting; and the antennæ are of the length of the thorax.

Most animals are infested with *lice*, or insects, which feed upon them; thus sheep have one species, oxen another, &c. and mankind are not free from them. For beside the common kind, whose natural habitation is in the heads of children, there is another kind called the *crab-louse*, whose residence is about the pubes. Linnæus enumerates no less than forty different species, distinguishing them by the several animals to which they belong.

The *louse* affords to the microscopic observer of the works of the creation, a very delicate and beautiful structure of parts. See *Tab. of Microscopical Objects, class* 1.

This creature has so transparent a shell, or skin, that we are able to discover more of what passes within its body, than in most other living creatures. It has naturally three divisions, the head, the breast, and the tail part. In the head appear two fine black eyes, with a horn that has five joints, and is surrounded with hairs standing before each eye; and from the end of the nose, or snout, there is a pointed projecting part, which serves as a sheath or case to a piercer, or sucker, which the creature thrusts into the skin, to draw out the blood and humours, which are its destined food, for it has no mouth that opens in the common way. This piercer, or sucker, is judged to be seven hundred times smaller than a hair, and is contained in another case within the first, and can be thrust out or drawn in at pleasure. Baker's Microscope, p. 177.

The breast is very beautifully marked in the middle, the skin is transparent, and full of little pits, and from the under part of it proceed six legs, each having five joints, and their skin all the way resembling shagreen, except at the ends, where it is smoother. Each leg is terminated by two claws, which are hooked, and are of an unequal length and size; these it uses as we would a thumb and a middle finger, and there are hairs between these claws as well as all over the legs. Lewenhoeck's Arcan. Nat. tom. ii. p. 74.

On the back of the tail part there may be discovered some ring-like divisions, abundance of hairs, and a sort of marks, which look like the strokes of a rod on a child that has been whipped; the skin of the belly seems like shagreen, and toward the lower end is very clear, and full of pits: at the extremity of the tail there are two semi-circular parts, covered all over with hairs, which serve to conceal the anus.

When the *louse* moves its legs, the motion of the muscles, which all unite in an oblong dark spot in the middle of the breast, may be distinguished perfectly, and so may the motion of the muscles of the head when it moves its horns. We may likewise see the various ramifications of the veins and arteries, which are white, with the pulse regularly beating in the arteries. But the most surprising of all the sights is the perillaltic motion of the guts, which is continued from the stomach down to the anus. Philos. Trans. N° 102.

If one of these creatures, when hungry, be placed on the back of the hand, it will thrust its sucker into the skin, and the blood it sucks may be seen passing in a fine stream to the fore-part of the head, where falling into a roundish cavity, it passes again in a fine stream to another circular receptacle in the middle of the head; from thence it runs through a smaller vessel to the breast, and then to a gut which reaches to the hinder part of the body, where in a curve it turns again a little upward. In the breast and the gut the blood is moved without intermission with a great force, especially in the gut; and that with so strong a propulsion downward, and such a contraction of the gut as is very surprising. Power's Mic. Obs. 9.

In the upper part of the crooked ascending gut before mentioned the propelled blood stands still, and seems to undergo a separation; some of it becoming clear and watery, while other little black particles pass downward to the anus.

If a *louse* be placed on its back, two bloody darkish spots appear; the larger in the middle of the body, the lesser toward the tail. In the larger spot, a white film or bladder contracts and dilates upwards and downwards from the head toward the tail, the motions of which are followed by a pulsation of the dark bloody spot, in or over which

the white bladder seems to lie. This motion of the syſtole and diaſtole is beſt ſeen when the creature begins to grow weak; and on picking the white bladder, which ſeems to be the heart, the creature always inſtantly dies. The lower dark ſpot is ſuppoſed to be the excrements in the guts.

Lice have been ſuppoſed to be hermaphrodites, but this is erroneous; for Mr. Lewenhoeck diſcovered that the males have ſtings in their tails, which the females have not. And he ſuppoſes the ſmarting pain theſe creatures ſometimes give to be owing to their ſtinging with theſe ſtings, when made uneaſy by preſſure or otherwiſe. And this accurate obſerver ſays, that he felt little or no pain from their ſuckers, though ſix of them were feeding on his hand at once.

The ſame accurate obſerver determining to know their true hiſtory and manner of breeding, put two females into a black ſtocking, which he wore night and day. He found, on examination, that in ſix days one of them had laid above fifty eggs; and upon diſſecting it, he found as many yet remaining in the ovary; whence he concludes, that in twelve days it would have laid a hundred eggs. Theſe eggs naturally hatch in ſix days, and would then probably have produced fifty males and as many females; and theſe females coming to their full growth in eighteen days, might each of them be ſuppoſed after twelve days more to lay a hundred eggs; which eggs, in ſix days more, might produce a young brood of five thouſand; ſo that in eight weeks one *louſe* may ſee five thouſand of its own deſcendents. A *louſe* may be eaſily diſſected in a ſmall drop of water upon a ſlip of glaſs; and thus placed before the microſcope, it is common to find five or ſix eggs of a ſize ready to be laid, and ſixty or ſeventy others of different bigneſs. In the male the penis is very remarkably diſtinct, as are alſo the teſtes, of which he ſeems to have a double pair, as is alſo the ſting, the ſtructure of which merits a peculiar attention. Lewenhoeck's Arcan. Natur. tom. ii. p. 78.

Many animals, both of the quadruped and flying kinds, are ſubject to *lice*: but theſe are of peculiar ſpecies on each animal, and are not at all like thoſe which infeſt the human body. Nay, even inſects are infeſted with vermin, which feed on them and torment them. Several kinds of beetles are very ſubject to *lice*, but particularly that kind called thence the *louſy beetle*. The *lice* on this are very numerous, but will not be ſhook off. The earwig is often infeſted with *lice* juſt at the ſetting on of its head; theſe are white, and ſhining like mites, but they are much ſmaller; they are round-backed, flat-bellied, and have long legs, particularly the foremoſt pair. Snails of all kinds, but eſpecially the large naked kinds, are very ſubject to *lice*, which are continually ſeen running about them, and devouring them. Numbers of little red *lice*, with a very ſmall head, and in ſhape reſembling a tortoiſe, are often ſeen about the legs of ſpiders, and they never leave the ſpider while he lives, but if he be killed, they almoſt inſtantly forſake him. A ſort of whitiſh *lice* are very common on humble-bees; they are alſo found on ants; and many ſorts of fiſhes are not leſs ſubject to them than the land animals. Kircher ſays, that he has found *lice* alſo on flies. Baker's Microſcope, p. 182.

Signior Redi, who has more accurately examined theſe creatures than any other author, has engraved ſeveral ſpecies found on different animals. He calls thoſe found on beaſts *lice*, and thoſe found on birds fleas. He is of opinion, that every ſpecies of birds has its peculiar ſort of flea, different from thoſe of other birds; and has obſerved that they are hatched white, but that they gradually acquire a colour, like that of the feathers they live among; yet they uſually remain tranſparent enough for a good microſcope to diſcover the motion of their inteſtines. The kinds he has obſerved are theſe: on the hawk three different ſorts; on the large pigeon, the turtle-dove, the hen, the ſtarling, the crane, the magpye, the heron, the leſſer heron, the ſwan, the turkey, the duck, the ſea-mew, the ſmall ſwan, the teal, the caſſtrel, the peacock, the capon, and the crow, on each one ſort; on the moorhen three ſorts; on the wild gooſe two ſorts; and on the crane, beſide the common one, a white ſort, marked, as it were, with Arabic characters. Men, he obſerves, are ſubject to two kinds, the common *louſe*, and that called the *crab-louſe*. He alſo found peculiar ſorts on the goat, the camel, thoſe, the African ram, the ſtag, which has like many of the birds, two kinds, and on the lion and the tyger. The ſame author has obſerved, that the ſize of theſe creatures is not at all proportioned to that of the animal they are to inhabit, for the ſtarling has them as large as the ſwan. Redi, Gen. Inſ. p. 312.

It is obſervable, that ſome ſort of conſtitutions are more apt to breed *lice* than others; and that in certain places of different degrees of heat, they are very certain to be deſtroyed upon people, who in other climates are overrun with them. It is an obſervation of Oviedo, that the Spaniſh ſailors, who are generally much afflicted with *lice*, always loſe them in a certain degree in their voyage to the Indies, and have them again on their coming to the ſame degree at their return: this is not only true of the Spaniards, but of all other people who make the ſame voyage; for though they ſet out ever ſo *louſy*, they have not one of theſe creatures to be found after they come to the tropic. And in the Indies there is no ſuch thing as a *louſe* about the body, though the people be ever ſo naſty. The ſailors continue free from theſe creatures till their return; but in going back they uſually begin to be *louſy*, after they come to about the latitude of Madeira. The extreme ſweats, which the working people naturally fall into between this latitude and the Indies, drown and deſtroy the *lice*, and are of the ſame effect as the rubbing over the *louſy* heads of children with butter and oil. The ſweat in and about the Indies is not rank as in Europe, and therefore it is not apt to breed *lice*; but when the people return into latitudes where they ſweat rank again, their naſtineſs ſubjects them to the ſame viſitations of theſe vermin which it uſed to have.

The people in general, in the Indies, are very ſubject to *lice* in their heads, though free from them in their bodies. The reaſon of this is, that their heads ſweat leſs than their body, and they take no care to comb and clean them. The Spaniſh negroes waſh their heads thoroughly once every week with ſoap, to prevent their being *louſy*. This makes them eſcape much better than the other negroes who are ſlaves there, for the *lice* grow ſo numerous in their heads, that they often eat large holes in this part. Mr. de la Hire has given a curious account of the creature which he found on the common fly. Having occaſion to view a living fly by the microſcope, he obſerved on its head, back, and ſhoulders, a great number of ſmall animals, crawling very nimbly about, and often climbing up the hairs, which grow at the origin of the fly's legs. He, with a fine needle, took up one of theſe, and placed it before the microſcope, uſed to view the animalcules in fluids. It had eight legs, four on each ſide; they were not placed very diſtant from one another, but the four toward the head were ſeparated by a ſmall ſpace from the four toward the tail. The feet were of a particular ſtructure, being compoſed of ſeveral fingers, as it were, and fitted for taking faſt hold of any thing; the two neareſt the head were alſo more remarkable in this particular than thoſe near the tail; the extremities of the legs, for a little way above the feet, were dry and void of fleſh, like the legs of birds, but above this part they appeared plump and fleſhy. It had two ſmall horns upon its head, formed of ſeveral hairs arranged cloſely together; and there were ſome other cluſters of hairs by the ſide of theſe horns, but they had not the ſame figure; and toward the origin of the hinder legs there were two other ſuch cluſters of hairs, which took their origin at the middle of the back. The whole creature was of a bright yellowiſh red; and the legs, and all the body, except a large ſpot in the centre, were perfectly tranſparent. In ſize, the author believes it was about a tenth part of the bigneſs of the head of the fly; he obſerves, that it is rarely that flies are found infeſted with them. Mem. Acad. Par. 1693.

LOUSE, *tree*. See APHIS.

LOUSE, *wood*. See MILLEPEDES.

LOUSE-*wort*, *pedicularis*, in *Botany*, the name of a genus of plants, of the *didynamia angioſpermia* claſs; the characters of which are theſe: the flower conſiſts of one leaf, and is of perſonated or maſked form, and divided into two lips, the upper one hooded, the lower one divided into three ſegments; the piſtil ariſes from the cup, and is fixed in manner of a nail to the hinder part of the flower; this afterwards ripens into a capſule, divided into two cells, and containing oblong, flatted, and marginated ſeeds. Linnæus enumerates fifteen ſpecies of this plant. The common ſpecies are very troubleſome weeds in paſtures.

LOUSE-*wort*, *yellow*, *rhinanthus*, in *Botany*, a genus of the *didynamia angioſpermia* claſs; the characters are, that the flower hath a permanent empalement of one leaf, which is roundiſh, compreſſed, and blown up; it hath one ringent petal, with a cylindrical tube of the length of the empalement, compreſſed at the baſe, but opening at the top; the upper lip is hooded, compreſſed, and indented at the point; the lower lip is plain, ſpreading, and cut into three obtuſe parts at the point; it has four ſtamina ſhut up in the upper lip, and an oval compreſſed germen, which becomes a capſule of the ſame form, with two cells, opening on the ſide and filled with compreſſed ſeeds. Miller enumerates three and Linnæus ſeven ſpecies.

The Dutch carry on a trade with the ſeeds and feed-veſſels of a ſpecies of this plant, reſembling the common yellow-meadow *louſe-wort*, to Germany, and call it *ſemen ſorodillæ*; they uſe it for deſtroying bugs: for this purpoſe, they boil a quantity of the ſeeds and capſules in common water, with which they waſh their wainſcots, bed-

bedſteads, &c. where theſe inſects are lodged, and thus they are effectually deſtroyed. Miller.

LOUVRE, in *Muſic*, a well known dance-tune.

LOUVRE is alſo the name of the royal palace at Paris.

LOUVRE, *bowers of the*. See HONOURS.

LOW *air*, in *Horſemanſhip*. See AIRS.

Low *ſhank, hemiſphere, maſs, ſtyle*. See the ſubſtantives.

Low-*bell*, in *Bird-ing*, a name given to a *bell*, by means of which they take birds in the night in open champaign countries, and among ſtubble in October. The method is to go out about nine o'clock in a ſtill evening, when the air is mild and the moon does not ſhine.

The *low-bell* is to be of a deep and hollow ſound, and of ſuch a ſize, that a man may conveniently carry it in one hand. The perſon who carries it is to make it toll all the way he goes, as nearly as may be, in that manner in which the *bell* on the neck of a ſheep tolls, at it goes on while it feeds. There muſt alſo be a box made like a large lanthorn, about a foot ſquare, and lined with tin, but with one ſide open. Two or three great lights are to be ſet in this, and the box is to be fixed to the perſon's breaſt, with the open ſide forwards, ſo that the light may be caſt forward to a great diſtance; it will ſpread as it goes out of the box, and will diſtinctly ſhew the perſon who carries it whatever there is in the large ſpace of ground which it extends over, and conſequently all the birds that rooſt upon the ground. Two perſons muſt follow him who carries the box and *bell*, one on each ſide, ſo as not to be within the reach of the light to ſhew themſelves. Each of theſe is to have a hand-net of about three or four feet ſquare, faſtened to a long ſtick or pole; and on which ever ſide any bird is ſeen at rooſt, the perſon who is neareſt is to lay his net over it, and take it with as little noiſe as poſſible. When the net is over the bird, the perſon who laid it, is not to be in a hurry to take the bird, but muſt ſtay till he who carries the light is got beyond it, that the motions may not be diſcovered. The blaze of the light, and the noiſe of the *bell*, terrify and amaze the birds, in ſuch a manner, that they remain ſtill to be taken; but the people who are about the work muſt keep the ſtricteſt quiet and ſtillneſs that may be.

Some people are fond of going on this ſcheme alone. The perſon then fixes the light-box to his breaſt, and carries the *bell* in one hand and the net in the other; the net, in this caſe, may be ſomewhat ſmaller, and the handle ſhorter. When more than one are out at a time, it is always proper to carry a gun. It is no uncommon thing to ſpy a hare when on this expedition; and, in that caſe, it is better to ſhoot her, than to truſt to the taking her in the net, for ſhe will very eaſily eſcape from that. Some tie the *bell* to their girdle, and carry the light in their left hand and the net in the right; the light is not to be ſo large in this caſe, and the other way is therefore rather the better.

Low-*bellers*, in our *Statute-Books*, are perſons who go in the night-time with a light and a bell; by the ſight and noiſe whereof, birds ſitting on the ground become ſtupefied, and ſo are covered with a net, and taken.

LOW, in the *Manege*—To *carry* LOW. See CARRYING.

Low-*water*. See WATER.

Low-*wines*. See *Low*-WINES.

To LOWER, in *Sea-Language*, is to eaſe down gradually, expreſſed of ſome weighty body, which is ſuſpended by tackles or other ropes, which, being ſlackened, ſuffer the body to deſcend as ſlowly or expeditiouſly as the occaſion requires. Hence *lower handſomely*, and *lower cheerly*, are oppoſed to one another; the former being the order to *lower* gradually, and the latter to *lower* expeditiouſly.

LOWERING, in the *Diſtillery*, a term uſed to expreſs the debaſing the ſtrength of any ſpirituous liquor by mixing water with it. The ſtandard and marketable price of theſe liquors are fixed, in regard to a certain ſtrength in them called PROOF; this is that ſtrength, which makes them, when ſhook in a phial, or poured from on high into a glaſs, retain a froth or crown of bubbles for ſome time. In this ſtate ſpirits conſiſt of about half pure, or totally inflammable ſpirit and half water; and if any foreign or home ſpirit is to be expoſed to ſale, and is found to have that proof wanting, ſcarce any one will buy it, till it has been diſtilled again and brought to that ſtrength; and if it is above that ſtrength the proprietor uſually adds water to it to bring it down to that ſtandard. This addition of water, to debaſe the ſtrength, is what is called *lowering* it. People well acquainted with the goods, will indeed buy ſpirits at any ſtrength, only *lowering* a ſample to the proof ſtrength, and by that judging of the ſtrength of the whole; but the generality of buyers will not enter into this, but muſt have it all *lowered* for them.

There is another kind of *lowering* in practice among the retailers of ſpirituous liquors to the vulgar, this is the reducing it under the ſtandard of proof. They buy it proof, and afterwards increaſe their profit upon it, by *lowering* it with water one eighth part. The quantity of ſpirit is what they generally allow themſelves for the addition of water; and whoever has the art of doing this, without deſtroying the bubble proof, as this is eaſily done by means of ſome addition, that gives a greater tenacity to the parts of the ſpirit, will deceive all that judge by this proof alone; that is, very nearly all who are concerned in the ſpirit trade. Such an additional quantity of water as one eighth, makes the ſpirit taſte ſofter and cooler, and will make many prefer it to the ſtronger ſpirit, which is hotter and more fiery; but unleſs the ſpirit, thus *lowered*, were tolerably clean, or the proof be ſome other way preſerved, the addition of the water lets looſe ſome of the coarſe oil, which makes the liquor milky, and leaves a very nauſeous taſte in the mouth. Shaw's Eſſay on Diſtillery.

The way to judge of ſpirits not being thus *lowered*, or debaſed in ſtrength, is to examine them by the eye and tongue; and in buying a quantity of proof goods, ſuch ſhould always be choſen as are clean, thin, and light, and have a good crown of froth which goes off in large bubbles, ſuch as taſte ſoft and uniform, and are not high flavoured, of an alcaline guſt, nor acrid and fiery, but ſoon quit the tongue.

LOWERING *the flag*. See FLAG.

LOWEST *region*. See REGION.

LOXIA, in *Ornithology*. See CROSS-*bill*. See alſo BULL-*finch*, COCCOTHRAUSTES, GREEN-*finch*, &c.

LOXODROMIC *table*. See TABLE.

LOXODROMICS, the art, or method, of oblique SAILING, by the loxodromy, or RHUMB.

LOXODROMY, LOXODROMIA, formed of λοξὸς, *oblique*, and δρόμος, *courſe*, the line which a ſhip deſcribes in ſailing on the ſame collateral RHUMB.

The *loxodromy*, called alſo the *loxodromic line*, cuts all the meridians in the ſame angle, called the *loxodromic angle*. This line is a ſpecies of the logarithmic SPIRAL, deſcribed on the ſurface of the ſphere, having the meridians for its radii.

LOYAL, in the *Manege*. A horſe is ſaid to be *loyal*, that freely bends all his force in obeying and performing any manege he is put to; and does not defend himſelf, or reſiſt, notwithſtanding his being ill treated.

A *loyal* mouth is an excellent mouth, of the nature of ſuch as we call mouths with a full reſt upon the hands.

LOZENGE, or LOZANGE, in *Geometry*, a kind of parallelogram, or quadrilateral figure, conſiſting of four equal and parallel lines, or ſides, whoſe angles are not right, but whereof two oppoſite ones are acute, and the other two obtuſe; the diſtance between the two obtuſe ones being always equal to the length of one ſide.

Scaliger derives the word *lozange* from *lauragia*; this figure reſembling, in ſome reſpects, that of a laurel-leaf. In geometry, it is ordinarily called RHOMBUS; and, when the ſides are unequal, RHOMBOIDES.

LOZENGE, in *Heraldry*, is a rhombus, or figure of equal ſides, but unequal angles; reſembling a quarry of glaſs in our old windows; placed erect, point-ways. See *Tab. II. Heraldry, fig.* 71. It is in this figure that all unmarried gentlewomen and widows bear their coats of arms becauſe, as ſome ſay, it was the figure of the Amazonian ſhield; or, as others, becauſe it is the ancient figure of the ſpindle.

The *lozenge* differs from the *fuſil*, in that the latter is narrower in the middle, and not ſo ſharp at the ends.

LOZENGES, among *Jewellers*, are common to brilliant and roſe-diamonds. In the former they are formed by the meeting of the ſtill and flat-facets on the bezil; in the latter, by the meeting of the FACETS in the horizontal ribs of the crown.

LOZENGE, is alſo a form of medicine, made into ſmall pieces, to be held or chewed in the mouth till they are melted there: the ſame with what are otherwiſe called *troches*, *troches*.

LUA, in *Mythology*, a Roman divinity mentioned by Livy, lib. viii. and invoked in war. The name is ſuppoſed to be derived from *luere, to expiate*.

LUBI, in *Botany*, a name by which many authors have called the *cocoznite-tree*, or *palma muſciferа medica* of other writers.

LUCAR, among the Romans, an appellation given to the money expended upon plays and public ſhews.

LUCARIA, an ancient feaſt celebrated by the Romans. Sext. Pompeius obſerves, that the *Lucaria* were ſolemnized in the woods, where the Romans, defeated and purſued by the Gauls, retired, and concealed themſelves. The word, according to Feſtus, and Sext. Pompeius, comes from *lucus*, a *grove*, or *wood*. Varro derives it from *lux*, the ablative of the word *lux, light* and *liberty*. But the former etymology ſeems the more natural.

It was held in the month of July, in memory of the aſylum they found in the wood, which was between the Tyber and the road called Via Salaria.

LUCE,

LUCE, *cæcitie*. See EAU *de luce*.

LUCERIUS, in *Mythology*, a name given to Jupiter, as *Lucetia* was given to Juno, as the deities which gave light to the world.

LUCERNA, in *Zoology*, the name of a fish caught in the Mediterranean and some other seas, of the oculus kind, and very nearly approaching to the shape and figure of the HIRUNDO. Its tail is but slightly forked, and what distinguishes it principally from the hirundo, is, that its side-lines near the tail divide into two, whereas in that fish they continue single; its scales are very small, and it has a furrow on the back, edged by twenty-five spines on each side; the gill-fins are of a remarkable size, and look like wings: it feeds on shrimps and other small animals. See *Tab.* II. *of Fishes*, N° 20.

LUCERNE, *medica*, in *Botany*. The flower, which hath a bell-shaped empalement of one leaf, cut into five equal acute points, is of the butterfly kind; the standard oval and entire; the border reflexed; the two wings are oblong, oval, and fixed by an appendix to the keel, which is oblong, bifid, and reflexed toward the standard; it has ten stamina, nine of which are joined almost to their tops, the other is single, terminated by small summits; it has an oblong compressed germen, which is incurved, sitting on a short style: this and the stamina are involved by the keel and standard; the germen afterward turns to a compressed moon-shaped pod, inclosing several kidney-shaped seeds. Miller enumerates eight species. Linnæus joins this genus to the medicago or *Snail* TREFOIL.

Lucerne, which is the greater upright *medica*, with purplish flowers, called also Burgundy hay, is frequently cultivated by our farmers in the manner of clover. It is the same plant which the ancients were so fond of under the name of *medica*, so called because it came originally from Media, and on the culture of which they bestowed such great care and pains.

Its leaves grow three at a joint, like those of the clover; its flowers, which appear in June, are purple, and its pods of a screw-like shape, containing seeds, which ripen in September, like those of the broad-clover, but larger and more kidney-shaped.

The stalks grow erect, and after mowing, they immediately grow up again from the parts where they were cut off. The roots are longer than those of the saint-foin, and are not single, but sometimes they run perpendicular in three or four places from the crown. Miller reckons four varieties of this species, the best of which is that with the purple flower.

This is the only plant in the world, whose hay is preferable to the saint-foin for the fattening of cattle; but its virtues, in that respect, are so great, that they are not to be credited by any that have not tried the plant. It is the sweetest grass in the world, but must be given to cattle with caution, and in small quantities, otherwise they will swell and incur diseases from it.

The ancients were at the greatest pains to plant this properly: they chose the fattest and best land they had for it, and this they dunged and laid out in beds as we do for the choicest garden-plants. They sowed it in the end of April, first carefully preparing the ground by breaking the clods, they then raked the earth over the seeds to cover them lightly, and when it was come up they carefully kept the beds clear of weeds. They sowed it very thick, and let the first crop of it stand till the seed was in part shattered out, that they might be sure of more plants in the beds; after this, they cut it as young as they pleased, and it usually yielded them four or five crops or more in a year. A land well planted with it, would, with proper management, last ten years, and produce largely all the time. It is computed that English gardeners make forty pounds of an acre of asparagus, or many other garden plants, with half the labour and expence that was bestowed upon an acre of the Roman *medica*. This was a piece of husbandry only practised while that great empire was in its glory; at present they have very little *medica* or *lucerne* in Italy, and what they have is manured in a less troublesome manner.

In the south of France there is annually a great quantity of it raised. They sow it alone in March, or in the end of September, choosing for this purpose dry and sandy lands, but such as lie low.

They prepare these by ploughing and harrowing them very fine, and the spring and autumn being rainy, they have no occasion to water the plants, while young, as the Romans did. The summers in that part of the world are much drier than in Italy, and by that means the grass is burnt up, and other weeds much destroyed, so that the crop does not want that vast expence in weeding that the Roman *medica* did: by this means the expence also is greatly abated.

On the banks of the Rhine *lucerne* is produced in great abundance, and may be mowed five or six times in a year.
